3. By a system of automatic heat storage supplied from the dispensable circuit, and arranged to absorb energy off the heavy load periods, and dispense the same automatically to maintain uniform temperature in the rooms—supplemented with a low-power radiator on the hearth in the case of sitting-rooms. Also to furnish the necessary heat for cooking operations requiring boiling water, low-pressure steam, and the like.
4. A consumer's load regulator which will automatically protect him from imposing a greater maximum load upon the supply than he is entitled to under the terms of his supply agreement.
5. A thoroughly organized department from which the cookers, heaters, and current using and controlling devices can be obtained on attractive hiring terms or hire-purchase.
6. The employment of one cheap and effective two-rate discriminating meter only on each consumer's premises.

We sincerely hope, on behalf of the gas industry, that the electrical industry will put the proposals of Mr. Wilkinson into speedy operation; for we are satisfied that one of the best ways in which the latter can serve the former is by doing its utmost to confuse the consumers it obtains for various domestic purposes, and to run up the electrical equipment of houses to a point which will have throughout a district a still more impressive advertising effect regarding installation costs.

Artificial Light Through the Window.

We have had no innovations in the application of domestic artificial lighting for some time past. The variations are between direct, semi-indirect, and wholly reflected lighting. Now a new idea is presented to us by the General Electric Company. During day time, the light of a room is derived solely from the window or windows. If that is correct for daytime, why should it not be so for night time? The Company contend that the disposition of lights overhead or on the walls in the conventional styles is wrong; and the home of the future will be illuminated from outside the window at night, the same as by day—the difference being that, when the sun is not functioning for this particular purpose, then artificial light supplied from outside the window will take its place, so that people in the room may fancy they are enjoying brilliant sunshine, although there is rather a deficiency of the natural variety in these times. What the Company appear to be doing under this system is to instal a group of lights outside the window, in an arrangement (it is said) something like a fern case; and by this means the effect will be produced of sunshine streaming into the room. "It will be," one report states, "synthetic sunshine; but it will be precisely the same in appearance as the real thing." We are a little sceptical of this new idea. The intensity of light differs as the square of the distance from the source. With artificial light streaming through a window, a room would be unequally illuminated—much more so than with in the room a centrally disposed source of illumination. Persons standing or sitting before the sources of the artificial sunlight would throw uncomfortable shadows. We can imagine that two or three people reading in a room under such conditions would all be compelled to sit with their backs to the light in order to see the print. That would not be pleasant, unless they were on unfriendly terms. The more we think about the idea, the less we like it; but perhaps an inspection of the system may change our views. Anyway, the electricians make a point of the hypothetical evils of having gas lights in a room. The unnatural sunshine proposition will annihilate the electrical objections to gas lighting. If the economical incandescent gas lights are situated in a case outside the window, and the light from them streams into the room, they will be equally as advantageous as electric lamps—perhaps more so, because of the purity of the light and the economy of supplying it, especially with preheated cluster burners. Of course, there is nothing new in the idea as applied to shop window lighting. The lighting of goods inside shop windows after daylight fails has often been carried out by externally applied lighting; it is only in domestic lighting that the system has not hitherto been adopted. We are reminded, too, of the lighting of the House of Commons through the glazed ceiling of the Chamber. But that is top lighting. It is not the same thing as a window in one of the walls of a room. However, fancy having to equip all the windows in a house with outside light sources, protected by something resembling a fern case. We hope to be defended from having the pleasant views from any of our windows obstructed in this way.

Registration of Contractors.

We have not for some time past referred to this matter. As will be remembered, the scheme was designed with the view of obtaining an authorized register of electrical installation contractors, in order to provide all concerned with a list of the firms of recognized repute in the industry. The Registration Board have recently held their annual meeting; and it is interesting to note how far they have progressed in their work. It appears that the applications for registration up to the date of the last meeting of the Board (March 14) total 728, of which 670 have been accepted. No less than 46 applications have been declined and withdrawn; and twelve additional ones are receiving consideration. These figures do not suggest that the register has secured the adherence of any large proportion of the whole number of really competent electrical contractors in the country. In London and the suburbs, without the large provincial cities and towns, there is a plurality of contractors, and from those quarters one would imagine that a very high percentage of the accepted 670 contractors could have been obtained. We do not wish in any way to belittle the effort that has been made; but if the register is to be really effective in weeding-out undesirable contractors from the wiring business, then very much more than this will have to be done. It is interesting also to notice that six municipalities—Manchester, Hull, Wolverhampton, Bristol, Preston, and Croydon—have taken official action in support of the register by issuing notifications to the effect that they will only consider tenders from registered contractors. Several engineers of other municipalities have expressed sympathy with and approval of the register, although official support cannot be given by them until instructions have been received from their respective authorities. The method which has been taken to make the use of the register effective is by circulating the information among consultants and architects. There has also been an amount of reliance on the efforts of the registered contractors themselves, who, when submitting tenders, draw special attention to the existence of the register, and the guarantee as to standing and quality of work which is connoted by admittance to the register. It is observed that the Executive Committee are proposing to collect as far as possible a complete list of all the electrical installation contractors in the country, with a view to keeping before those not yet registered the advantages of registration. With regard to publicity, last year two printed lists of names of the registered contractors were circulated to the registered firms, supply engineers, consultants, and architects. A third list is now in preparation; and it is hoped shortly to issue this to approximately 10,000 addresses. Builders, it is mentioned, are the next group to be dealt with. In the gas industry we should also find acceptable some scheme which made a serious attempt to eliminate shoddy work and inefficient appliances.

Scottish Junior Gas Association (Eastern District). A visit to the Leslie and Markinch Gas-Works has been arranged for next Saturday afternoon (the 16th inst.); and the annual outing will take place on June 6, at Anstruther.

How Gas Can Help the Cinema Industry.—Cinema proprietors are to-day seriously concerned at the high charges made for electricity for the lighting of the cinema arcs, and of the theatres themselves. They generally have to pay for current used at the lighting rates, which vary generally from about 4d. to 8d. a unit. It is not surprising to find, therefore, that many of them are now generating their own current on the premises. For this purpose they are installing dynamos driven by gas engines, and in most cases have found that they can, by this means, get all the current they require at an inclusive cost of from 1½d. to 2½d. per unit. Several cases are mentioned in the current issue (No. 134) of "A Thousand-and-One Uses for Gas" in which the bill for electricity has been reduced by one-half as the result of local generation.

British Empire Exhibition, 1925.

The Gas Industry's Exhibit.

A MESSAGE FROM THE CHAIRMAN OF THE GAS EXHIBIT GENERAL COMMITTEE,

Mr. D. MILNE WATSON, M.A., LL.B., D.L.

THE British Empire Gas Exhibit Committee have endeavoured to make the 1925 Exhibit surpass in interest and importance that of 1924, which, by common consent, was of the highest value to the industry at home and abroad.

The Committee acknowledge with gratitude the splendid financial support already accorded to them. Nearly £28,000 has been received from 394 Gas Undertakings, and £6000 (estimated) from the makers of plant and apparatus. They look with confidence to the remaining Gas Undertakings in the Empire to add their proportionate subscriptions to the fund, so that adequate publicity may be given to this co-operative enterprise—for in that lies no small part of its potential value.

It is further hoped that the Gas Undertakings throughout the country will do everything in their power locally to interest the public in the Exhibit, and persuade them to visit it when at Wembley; and that the weather will be kind!

Then we may anticipate that the success of last year will be surpassed, and a further impetus given to the advancement of the industry in the service of the Empire.

AIM OF THE GAS EXHIBIT.

By F. W. Goodenough, Chairman of the Executive Committee.

The Gas Exhibit at Wembley in 1925, though housed in the same main structure, and having the same object in view, is essentially different from that of 1924 in detail and in method, as a visit to Wembley—or a reading of the "Journal" description—will make clear. But it is the object that is important, rather than the details.

The object in view in both years has been to impress the public mind with the magnitude, scope, and progressive vitality of the gas industry; with its ever-increasing achievements and possibilities of service to the individual, the community, the nation, and the Empire.

To do that by an exhibit within an Exhibition of such multifarious interest and on such a vast scale as that at Wembley, is no easy task. Some measure of success was achieved last year. Given sufficient attendance of the public this year, it is hoped that a greater measure of success may, through the experience gained in 1924, be achieved in 1925—especially if every gas undertaking does its share in advertising the existence of the exhibit to the consumers in its district before they make their pilgrimage to Wembley; incidentally advertising effectively the "aliveness" of the gas industry to those consumers whether they visit Wembley or not, as will the general publicity campaign and the Press comments on the Gas Exhibit.

There are two things that the Gas Exhibit at Wembley is not, and could not in the nature of things be. It is not an exhibition of every gas fitting, gas appliance, and gas making and measuring apparatus on the market, for the interest and education of the gas manager and his staff—and at the same time the confusion of the man and woman in the street—such as gas exhibitions sometimes are; any more than a poster is, or can be, a catalogue. General impression, general effect, is all that one can hope to achieve with a particular exhibit within a vast and variegated exhibition. For the same reason, the Gas Exhibit at Wembley is not a showroom in which every consumer from every corner of the country can obtain the same detailed assistance in selecting fittings and appliances suitable for his own home or place of business as he should be able to obtain in the showroom of his local gas undertaking. Every effort will always be made to give individual visitors personal attention, accurate general information as to the advantages of gas, and detailed information as to the maker and list price of everything exhibited; but beyond this—unless the attendance of the public were so small that the Exhibition were a failure—it would obviously be impossible to go.

These are points that need to be borne in mind sometimes by gas experts criticizing a gas exhibit such as that at Wembley. "Gas is a great and growing industry; gas can be used with advantage by rich and poor alike; gas fittings and appliances can be made to harmonize with any style of furnishing and decoration, however simple or however luxurious. Gas is a great servant, domestic and industrial, not only of the Mother Nation, but of the world-wide British Empire; the gas industry has a great past but a still greater future; the gas industry was never more alive, alert, and advancing than it is to-day." These are the broad, all-important, all-impressive facts with which the Gas Exhibit aims to inform the public thought, and fire the public imagination in 1925, as in 1924. The complete catalogue, the detailed showroom, the itemed quotation, the actual order—these are the business of the local undertaking to provide and to secure. The Exhibit is an advertisement—almost in the nature of a poster—to attract, to interest, to create desire in the passer-by. If it attempted to be or to do more, it would fail because of over-detail, narrowness, confusion.

This year the broad note of this advertisement of gas is its world-wide utility and popularity; the fact that the most virile children of the Motherland use gas in ever-increasing degree; that it is, like the British race itself, ever renewing its youth, not passing into old age and decrepitude; that it occupies a great and growing place in the economics of the Empire. Was there ever a year in which such a note in publicity was more timely than in 1925? Is there any gas undertaking in the British Empire that will not readily subscribe to the cost of such an effort for the benefit of all?

1924. 1925.

THE NEW WEMBLEY.

OPENING BY THE KING.

On Saturday last the 1925 Season of the British Empire Exhibition was declared open by H.M. the King. The British Nation have a gift for ceremonial pageantry ; and the pomp and circumstance of the opening ceremony, which was witnessed by over sixty thousand people, once more reminded us of our magnificent tradition, and of the importance and high endeavour of the Exhibition. The spectacular and musical splendour of the ceremony, and the unbounded enthusiasm of those who witnessed it, were fitting tributes to the efforts of all who have aided at making the Exhibition of even greater appeal than it was last year.

Last season Wembley challenged one of the worst summers on record; and though before noon on Saturday the sun shone brightly, it was a strange coincidence that, just as the Exhibition was declared open, there should be a shower of rain. It was, however, only a shower; and for the rest of the day the weather was delightful. Hope was that the last adverse effort of the weather god had been made, and that he had decided, after showing his strength, not to interfere with the success of the 1925 season of the Exhibition. On the opening day last year 63,000 people entered the Exhibition; this figure was nearly doubled last Saturday.

In asking the King to declare the Exhibition open, the Duke of York, who is the President this year, said that the date had been chosen as being the fifteenth anniversary of the coronation of the King. "The benefits which flowed to the Empire from the holding of the Exhibition in 1924," continued His Royal Highness, "were so marked that it was decided to continue it for another year. The 1925 Exhibition has integrally the same purpose as in 1924—to show how great are the resources available within the Empire; but while the Exhibition thus maintains the same character, it will present its lesson of Empire in a new manner. . . . The aim has been to provide not only a complete university of Empire, but a great pleasure and recreation ground."

Points from the King's Speech.

The King, in reply, said: "The British Empire depends for its security and prosperity on goodwill between its constituent peoples; and the one sure foundation for that goodwill is a full knowledge of our mutual aspirations, capacities, and needs. To seek knowledge, more knowledge, and again more knowledge of the great heritage which has been entrusted to us, is the soundest Imperial policy. I recognize the British Empire Exhibition as a successful instrument of that policy. . . . This year the Exhibition has wisely decided to present its lessons in a lighter and brighter form. All who come here must receive some prompting to serious thought on their duties and responsibilities; those who come to be entertained will remain to be educated, and will return to be further educated. . . . It was a happy inspiration to make housing and housebuilding a central feature of the Exhibition. For the foundation of the Empire is in the home; and the provision of houses in which a healthy home life is possible is a matter not only of domestic but of Imperial importance."

Immediately after the opening of the Exhibition, a formation flight of eight aeroplanes swooped down upon the stadium, and then rose again and were lost to sight. This, perhaps, was one of the most impressive items of the ceremony.

Wembley in 1925.

All who visited Wembley last year will agree that the British Empire Exhibition is the most outstanding utterance of which our generation is capable. Wembley serves as a focus of the might, the achievement, and the progress of the greatest Empire that history has known; and it is for every citizen to maintain and encourage the new phase of a vast endeavour. There are certain features of this year's Exhibition which mark the measure in which the lessons of 1924 have been mastered. As one enters, one is glad to see that the absurdly inconvenient turnstiles of last year have been removed, so that people with figures resembling that of Dr. Johnson no longer have to suffer the indignity of passing through a special gate in order to enter the grounds. Also, the entrances themselves have been made more worthy of the Exhibition. Last year the roads at Wembley left a great deal to be desired. Most of the roads within the grounds have been practically rebuilt, and the monotony of the grey surface has been relieved in places by the use of coloured gravel. The surroundings of the Lake have been greatly improved by making new rock gardens, opening fresh approaches to the shores, and reshaping the islands. As for the gardens, these are much more beautiful. The mere fact that they have had a year in which to mature means much. Besides a matter of 100,000 spring plants which are now in blossom, great numbers of new ornamental shrubs have been planted, new lawns have been made at various places, and areas which last year were neglected have been converted

Chairman of the Gas Exhibit Committee.

MR. F. W. GOODENOUGH.
Chairman of the Executive Committee.

into attractive garden patches. Last Saturday everything was running smoothly inside the grounds, and in spite of the vast crowds, no rubbish was to be seen on the paths. During the opening weeks of the Exhibition last year, proper arrangements had not been made for dealing with this problem. In another article dealing with the uses of gas in the Exhibition, mention is made of the application of gas to the destruction of this rubbish.

With regard to the lighting of the grounds, the Authorities were so pleased and satisfied with the gas lighting last year that no alteration has been made. The electric lighting last year, however—and this was readily admitted by the electricians themselves—was inadequate; and the scheme of illumination by electricity has been considerably amplified. Coloured lights among the foliage of the trees, the picking out of the architectural features of the main buildings with lights in tinted bulbs, irradiation of jets of steam—these and other devices combine to make the appearance of the grounds by night better and brighter than it was last year.

British Government Pavilion.

No section of the Exhibition drew a larger patronage or louder praise in 1924 than the British Government Pavilion. The lions on guard, the towering columns, the effect of the windows of the Royal rooms—all attracted the attention of visitors, who found their hopes of an interesting display well fulfilled within the Pavilion. This year most of the attractions remain the same. The Fuel Research Board are again showing their laboratory apparatus for the assay of coal for carbonization purposes; and charts indicate the effects of heating by coal, gas, and electric fires. As before, there is an exhibit of the Lessing coal assay apparatus. There is also an interesting and exceedingly well-drawn series of paintings showing the development of heating from early times to the present day. This illustrates graphically the desirability of using only non-smoke-producing fuels for domestic heating.

Palace of Industry.

The Palace of Industry remains very much the same as last year. Working exhibits are the rule rather than the exception. Wherever it is possible, there is movement. The practice of joint furnishing and decoration by industries or by groups of exhibitors has been recognized and is largely in evidence, so that it is easier than before to grasp the significance, extent, and variety of any representative display.

The Gas Light and Coke Company provide a stand showing their well-known products, such as tar, ammonia, and cyanogen compounds, β naphthol, cresol, &c. The South Metropolitan Gas Company display thirty-five samples of "Metro" chemicals. The stand is in the form of four towers, separating intermediates, ammonia products, coal-tar derivatives, and heavy inorganic compounds. Each tower is surmounted by a brazier containing smokeless coke fuel.

The exhibit by the Association of British Chemical Manufacturers occupies 40,000 sq. ft. This year Brunner, Mond, & Co., Ltd., are exhibiting their grey pressed bricks, which are less pervious to moisture than the common brick. Specimens of silica of soda are again shown; and two comparatively little known uses for this material are receiving special emphasis. The first is a method of road making which has had excellent results in France and Switzerland. The process is similar to that employed in the case of ordinary water-bound roads, except that a mortar of fine limestone and silicate of soda is used to bind the whole together. A great advantage to be derived from the use of silicate of soda is that the best results are obtained with soft porous chalky limestone, which is normally worthless for road construction, and in many districts can be obtained much cheaper than the hard materials. The advantages to be gained by treating the surface of concrete with a solution of silicate of soda are again being emphasized.

Nobel Industries are wisely giving prominence to the products of their various subsidiary Companies. One of their Companies—Lighting Trades, Ltd.—demonstrate the knitting, manufacture, and testing of gas mantles—a working exhibit which is attracting a great deal of attention. Chance & Hunt, Ltd., of Oldbury, are among the Companies associated with Brunner, Mond, & Co., and are exhibiting with them at the same stand, as also are the Castner-Kellner Alkali Co., Ltd.

The Graesser-Monsante Chemical Works, Ltd., show interesting specimens of phenol and cresol derivatives. The stand of the United Alkali Company, Ltd., is arranged to indicate the various products of the Company which are used for particular industries—for example, dye making, dyeing, paper and glass manufacture, &c.

Last year a section of the Palace was set apart for the display of the results of technical research; several Universities and Institutes combining to make an exhibit which rendered possible an appreciation of the enormous amount of scientific investigation undertaken in the immediate past. This year this section, which as yet is not complete, contains a model of a gas-works—unfortunately of an out-of-date pattern. There is also a model of a column-guided gasholder by Ashmore, Benson, Pease, & Co., Ltd.; the Regenerative Coal Gasification System, Ltd., have a diagram of their single-stage coal gasification machine; Babcock & Wilcox, Ltd., show a marine

MR. J. WILFRID DRAKE.

Chairman of Council, Society of British Gas Industries.

water-tube steam boiler adapted for land purposes; and there is a model of an ammonia recovery plant in connection with producer gas. A showcase contains botanical specimens, due to J. Walton, of Victoria University, Manchester, which demonstrate the part played by plants in the formation of coal. The Rose Patent Fuel Company exhibit briquettes. Other exhibits indicate the value of ammonia sulphate as a fertilizer. The "Adco" process for the manufacture of synthetic manure from straw and other vegetable residues is explained. Perhaps the most interesting exhibits in this section are the models of the Woodall-Duckham Companies, referred to on a later page.

Palace of Engineering.

Last year the Palace of Engineering told of achievement in a field which the English-speaking world has gone far to make its own. This year our needs, rather than achievements, are considered. These are better housing and better transport. In the housing section the visitor can see the varied types of houses that are intended to solve the problem of providing ample and comfortable accommodation at a moderate price. There are houses of steel and concrete, timber houses of a frankly utilitarian nature, and a concrete and oak combination. The display of building materials certainly presents many novelties. The railway exhibit occupies nearly 20,000 sq. ft. It shows not only the most modern of our equipment, but also the provisions which have been made to ensure both comfortable and safe travelling. Probably the most interesting feature of the motor section is the exhibition of mass production as applied to motor cars. The Ford Motor Company, Ltd., of Manchester, assemble cars; and an electrically driven moving platform, 100 ft. long, is seen in action. This conveyor moves between two rows of men, each of whom performs the operation allotted to him. By the time the last man has done his bit, the completed car slips from the conveyor, and can be driven away under its own power.

This year special attention has been given to caring for the children at the Exhibition, and in addition to a Children's Welfare Club, there is a "Treasure Island" which will delight the heart of any youngster. As for the Amusements Park, this is as gay and as popular as ever. As a technical and industrial Exhibition, the Wembley of 1925 cannot be considered an advance on the Wembley of last year; but there is no question that it is a brighter, more beautiful, and more entertaining place than formerly. It is to be hoped that the weather will be more favourable than it was last season. If it is, there can be no doubt of the success of the Exhibition.

"Examples in Machine Design."—This is a new volume published by Sir Isaac Pitman and Sons, Ltd. (price 6s. net), and written by G. W. Bird, W.Ex., B.Sc. It contains many typical designs illustrating standard engineering practice, and is suitable for students taking this subject for an engineering degree examination.

THE GAS SUPPLY TO THE BRITISH EMPIRE EXHIBITION.

By G. L. Jennings, Deputy Chief Inspector, Brentford Gas Company.

The second Exhibition at Wembley will be supplied with gas by the Brentford Gas Company.

Readers of the "Journal" are aware of the provisions that were made by that Company last year to afford the necessary quantity at a proper pressure; these remain practically the same as before. The gas is taken into the Exhibition through an 18-in. main, and the whole of the gas is supplied to the Exhibition Authorities, who are responsible to the Company for payment of all gas consumed in the Exhibition. This is advantageous, as a large quantity of it is consumed by the Exhibition Authorities direct. As a result, supplies to lavatories where gas is employed for the production of the necessary hot water, to lamps, Exhibition offices, fire stations, ambulance stations, &c., need not be metered, unless the Authorities desire to check the amount actually used at any particular place. All other consumers obtain their gas through the Authorities; and the amount is registered on various meters. In practice this is found to be the best method of dealing with large Exhibitions, as it reduces considerably the number of meters required.

Satisfactory Supply.

The mains remain as before—a 12-in. circular main round the area, from which subsidiary mains of 6-in. and 8-in. diameter are carried. These are available for the necessary supplies to the exhibitors. The larger buildings—the Palaces of Industry and Engineering—are traversed by these mains, so that at practically any point a supply is available. The mains inside the Exhibition amount to a little over seven miles; and last year no shortage of gas was found at any point. As a matter of fact, with the exception of one from a consumer who doubled his use of gas without increasing the size of his meter, there was no complaint of any sort throughout the season.

Extended Uses of Gas.

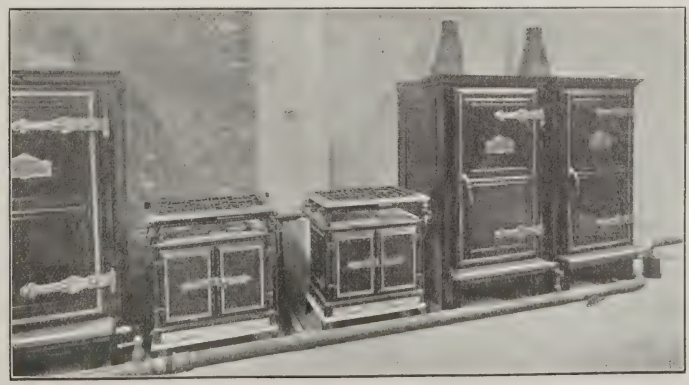
Gas will be used this year for practically the whole of the catering. Previously Messrs. J. Lyons & Co. did this catering, but this year it has been split-up among a number of firms. The gas apparatus installed by Messrs. Lyons, however, remains for the use of their successors. In addition the catering has been considerably extended; new buffets and cafés having been fitted up. There is now the "Excursionists' Restaurant," situated in the Palace of Transport and Housing, and so arranged that 7500 people can be dealt with for breakfast, lunch, tea, or dinner. It will not be available for the general public using the Exhibition, but will cater, as its name implies, for large bodies of excursionists visiting Wembley. Messrs. Allnatt's are running this special restaurant. To ensure quick service to so large a body of people, gas-heated hot closets in groups in various positions have been fitted, so that, after the joints have been cooked in the large gas roasting ovens (capable of roasting 2 tons of meat at a time), they can be kept hot and quickly served from the various groups of carving tables. There will be over twenty of these gas-heated carving tables in the dining hall. The vegetable cooking and necessary auxiliary services are dealt with in the kitchen; and for this purpose a 6-in. supply has been taken in, and an 800-light meter installed. It will probably be much the largest restaurant in the Exhibition. In addition, new cafés, with gardens, will be found behind the "Witching Waves" and close to the "Great Racer." Further buffets have also been installed in the Palace of Industry.

The Ceylon building, which originally had two tea kitchens, has now an additional large kitchen which will be run by Messrs. Gunters. The hot water for washing-up purposes will be supplied from two Potterton boilers; and gas apparatus has been installed for dealing with the necessary cooking. The Brentford Gas Company's "Regulus No. 1" cookers are in use for this purpose. British Guiana have also installed gas-heated apparatus to enable teas to be served in their exhibit. It is evidently the intention of the catering firms to see that full provision is made for dealing with the needs of the large number of people who are expected at the Exhibition this year. Additional gas supplies have been taken to the Gas Exhibit this year; and the main portion of the Exhibit, which was previously supplied with 300-light and 80-light meters, will now call for two 300-light meters.

General Exhibitors and their Requirements for Gas.

Messrs. Carsons, the chocolate and confectionery firm whose exhibit and the whole of its working parts were driven by a Bonecourt boiler last year, have now installed one of greater capacity, and a 500-light meter has been fitted in place of the 250-light meter they previously had. Messrs. Baker Perkins are also calling for larger supplies of gas in connection with the gas-heated travelling ovens they are installing. West Africa also have demanded a larger supply. Other exhibitors are Messrs. Brown & Polsons, Messrs. Horlicks, Messrs. Poppetts, and Messrs. Burnards & Son, who are requiring large supplies of gas in connection with a gas-heated steam boiler. A 200-light meter has been installed for them. They are fitting a Cochran boiler, entirely heated by gas. An idea of the size of this will be conveyed by the fact that it is capable of generating 15 H.P. It will be used chiefly for the manufacture of ice cream for the exhibition; it will work in conjunction with an ammonia plant, and is capable of delivering ice in large quantities. The temperature of the rooms used for ice making will be 20° below zero—over 50° of frost. In addition, the steam from this boiler will be used for sterilizing and washing the milk apparatus. This exhibit will be well worth the attention of those interested in the use of gas. Messrs. Grimble & Co., in the Palace of Industry, Messrs. Green & Gordon, the Polivit Manufacturing Company, Messrs. Oxo, Messrs. Entwistle & Kenyon—all are using gas. Additional supplies have been laid to New Zealand and to the Anglo-Indian Pavilion. Then there are the Pure Confectionery Company, the Price Candle Company (who use gas in connection with the melting of wax and the making of candles), Messrs. Geiple, Messrs. Levey & Co., Messrs. Nobel, the Gourm Manufacturing Company, and Messrs. Maynards (for the manufacture of sweetmeats, &c.).

In addition to the gas required for catering and by exhibitors, the Exhibition Authorities need a large amount in connection with their staff requirements. For instance, gas-heated geysers are installed in various places for the use of the members of the Fire Brigade, the ambulance stations, and for the production of hot water in the lavatories. That this quantity is considerable is shown by the fact that during the period while the Exhibition was closed to the general public—that is to say, from the beginning of November last to the beginning of April—the amount of gas consumed in the Exhibition was 4¾ million c.ft. This quantity will, of course, be considerably increased as soon as the Exhibition is opened.



EXCURSIONISTS' RESTAURANT, SHOWING FLETCHER RUSSELL ROASTERS AND "REGULUS" COOKERS.

EXCURSIONISTS' RESTAURANT, SHOWING GAS COPPERS AND THE METER.

Lighting.

The general lighting of the Exhibition will be as before. There has been practically no change in this so far as gas is concerned. The lamps will be Messrs. Staniforth's 16-light "Wembley" type; and though the Amusement Area will present a new appearance through the re-arrangement of buildings, the lighting will remain as before. It gave great satisfaction to the Authorities last year; and they have decided to let it remain. It was hoped that there would be a considerable extension of this; but owing to the circumstances in which the Exhibition Authorities were placed, they have not seen their way to extend it.

In connection with the gas lamps in the Amusement Area, the method of arriving at the consumption of these was to meter a certain number of them, and then take the average consumption, which was under 34 c.ft. per lamp per hour. Having regard to the fact that each lamp had 16 mantles, and that the lamps were kept at their maximum efficiency, this is a figure which is quite satisfactory. The maintenance of the lamps will again be carried out by the Brentford Gas Company, who keep a special staff of maintenance men for this work. Every lamp is inspected daily, and the glass cleaned. In dry weather it is found that dust renders such daily cleaning necessary, in order to ensure the best results being obtained.

Gas and Electricity.

Reviewing the position generally, it is expected that the amount of gas consumed in the Exhibition this year will exceed that in 1924; though this must to a large extent depend upon the weather. The figures published of the number of heat units supplied to the Exhibition last year by the Brentford Gas Company may be of interest. They show the extraordinary preponderance of gas, calculated on a heat basis, over electricity. The figures were: Gas, well over 40,000 million B.Th.U.; electricity, slightly over 30,000 millions.

GAS IN THE CATERING ESTABLISHMENTS.

The figures given by the Chairman of the Brentford Gas Company, showing a very large consumption of gas at the Exhibition, have naturally drawn attention to where this amount is being used. In another article are described some of the directions; but it is felt that the catering at the Exhibition, and the gas consumed by that catering, have not been sufficiently dealt with.

In this article is given a description of some of the gas appliances fixed in the British Empire Exhibition. Last year the whole of the catering was done by Messrs. J. Lyons & Co., and the kitchens were all laid out by them according to their usual scheme for catering. When Messrs. Lyons decided to discontinue their contract, the kitchens were left by them fitted with all the apparatus, and available for whatever firm took over the work. The majority of these firms have continued with this apparatus, as described, and some have added additional appliances. In the following, the individual kitchens are described.

The Grill Room.

The large Grill Room is being run this year by Gordon Hotels, Ltd. This is probably the most important restaurant in the Exhibition grounds, and is the one in which most gas is used. It is supplied by two 500-light meters off a 6-in. main, and coupled to 4-in. supplies; the outlet runs are also 4 in. The kitchens, which are very roomy, contain large roasting ovens, and a special battery of Cox grills capable of dealing with a great number of chops and steaks. The roasting ovens and hotplates here are 15 ft. long. There are four of these hotplates, which can deal with enormous quantities of foodstuff. The salamanders are important; and there is a large installation of these. The consumption of gas in this kitchen at busy times averages as high as 8000 c.ft. per hour. The large carving tables are gas heated. This Grill Room was originally fitted by Messrs. Lyons, who fully realized the advantages of using gas in any operation for which it was feasible.

The Bank Café will be run this year by the Aerated Bread Company. This is the Café which at one time was known as the "Electric," though the amount of electricity used in it, so far as cooking is concerned, was *nil*. It is fitted with a Wright's "Eureka" cooker, a large fish frier with triple pans, a large gas-heated hot closet and a hot table fitted with Keith & Blackman's new self-cleansing burners. These burners have been installed in very large numbers throughout the Exhibition. They are fitted with a convex cap, and are surrounded by refractory material. The flame plays upon this, and cannot be stopped by reason of the spilling of any sugar or fat. If any is spilt, it is promptly burnt, and falls off. There is a 150-light meter here, and the service to this café is 3 in., fed from the 8-in. main laid in the Avenue.

The Wembley Garden Club.

The restaurant previously known as the Lùcullus is now part of the Wembley Garden Club. The gas is supplied to this by a 300-light meter made by the Gas Meter Company, fitted with 4-in. supplies.

All meters throughout these cafés are controlled both on the inlet and outlet, so that in the case of exchanging a meter, the work can be done very quickly.

The kitchen is fitted with two "Falcon" stoves, made by the Falkirk Iron Company, with six ovens each and six boiling burners. There is a large Keith & Blackman boiling burner of the self-cleansing type; two double-tiered salamanders, and two double-tiered roasters. The hot closets here are heated by steam; and the boiling water is obtained from Still boilers. In addition there are a number of gas-heated closets.

The Colonnade Café is being run by the Aerated Bread Company. It has a 150-light meter and a 4-in. service. There is a hotplate here, fitted with a Keith & Blackman triple burner of the cleansing type, as previously described; also an 8-burner Keith hotplate, a gas-heated hot closet, a large gas-heated fish frier, two four-tiered Cox grills, a Wright's "Eureka" cooker, Still boilers, small toasters, additional gas-heated urns for milk, &c., egg boilers, and toasters and egg poachers combined.

The Orange Tree Buffet, previously the Garden Buffet, is supplied by means of a 2-in. service and a 100-light meter, and is fitted with gas-heated apparatus chiefly for producing hot water for teas.

The Tree Buffet is being run by Messrs. Bertram & Co. This buffet is very well named. It has two trees growing through the centre. It was felt desirable that as many trees as possible should be retained; and this is one of the few places

BROOK RESTAURANT (A.B.C.), SHOWING COX'S GRILLS AND ROASTERS.

where they are actually inside the building and growing through the roof. Visitors to the Exhibition should certainly see this interesting sight. The boiling water is produced in this buffet by means of Still boilers, of which three large ones are installed. The hot water for washing-up purposes is obtained from a Keith & Blackman circulating boiler. There is a 3-burner hotplate of the Keith & Blackman cleansing type, and a Wright's "Eureka" cooker. A 100-light meter and a 3-in. service supplies this buffet. The equipment here is typical of the whole of the buffets throughout the Exhibition, so that I do not intend to describe the remaining ones.

The Colonnade Restaurant, a "quick-lunch" café, is run by Messrs. Bertram. It is fitted with a Wright's "Eureka" cooker, a Keith Blackman circulating boiler, hotplates by the same firm, and Still boilers.

The North Institute deals with the supply of food to the workmen, and feeds a number of the employees in the Exhibition. It is fitted with Keith & Blackman hotplates, and large roasting ovens made by the Falkirk Iron Company. The boiling water is supplied by Still boilers. There is a 100-light meter and a 3-in. supply. The latter is carried on concrete piers across the brook which runs through the grounds. It can be seen under the Non-Stop Railway, adjoining the Wembley Park entrance to the Exhibition. It is a Mannesmann steel main, supplied off the 10-in. main carried through the Amusement Park.

Into the Brook Restaurant, which was previously known as the Popular, the Brentford Gas Company carried a 6-in. main, to which is attached a 500-light meter by Messrs. Parkinsons. There are two large roasting ovens made by the Falkirk Iron Company, a battery of four Cox grills, gas-heated fish frier, four large hotplates of the self-cleansing type, two salamanders, gas-heated hot closets, and a battery of Still boilers.

The Dancers Café is supplied through a 3-in. service and a 100-light meter. Its equipment is similar to the other cafés.

The Central Café, previously the Regent, is being run by Messrs. Buzzards, and is a very good example of a gas kitchen. It was, of course, originally fitted-up, as all the other kitchens were, by Messrs. Lyons; and this, to a great extent, accounts for the similarity of the installations. It contains a gas-heated hot closet, a battery of Cox grills, large gas-heated ovens with hotplates 15 ft. long, large batteries of double-tiered salamanders, three large roasting ovens, and six Still boilers. In the pastry kitchen is installed a "Falkirk" pastry oven, together with Keith & Blackman's hotplate, with self-cleansing burners, for making custards, jellies, &c. This restaurant is supplied by a 500-light meter off a 6-in. main, and the kitchen is one of the best in the Exhibition. The premises are well ventilated and of adequate size.

The Harmony Restaurant, which is being run by Messrs. Bertram & Co., is a "quick-lunch" café. This has a comparatively small kitchen, and is supplied through an 80-light meter.

The Grand Restaurant, which the Gordon Hotels are running this year, is fitted with large pastry ovens, two double-tiered salamanders, two large hotplates with ovens, and two large gas roasters. The meter supplying this is a 300-light, with 4-in. connections. This also applies to the buffet adjoining, where the installation is chiefly used for boiling water for the provision of teas. Still boilers are in use here.

The Veda Café is now run by the Veda Bread Company. This has the usual equipment of an ordinary café, with extra cooking capacity; and for this the Brentford Gas Company's "Regulus No. 1" cooker is in use.

South East Institute.

There is also the South East Institute catering for employees of the Exhibition. The equipment of this is very similar to the North Institute, which has already been described. They are both run by Capt. Symons, V.C. The Institutes are naturally a great boon to the large number of people who are employed

BROOK RESTAURANT, SHOWING KEITH-BLACKMAN HOTPLATES AND SALAMANDER.

ENGINEERING EAST (HAYMARKET HOTELS).

in patrolling and caring for the grounds and gardens, and generally seeing to their welfare. It is important, of course, that meals should be ready quickly. For this purpose, gas has proved its efficiency, and is generally adopted for any purpose for which it can be used. To this Institute a 3-in. supply has been run, and a 100-light meter fixed.

The Institute is situated near the refuse destruction apparatus of the Exhibition, which gave great trouble last year. It was found that the wet refuse, orange peel, &c., would not burn freely, but smouldered and caused large volumes of smoke, which proved annoying to the visitors to the Exhibition when the wind was in a certain direction. The Brentford Gas Company volunteered their assistance; and each of the incinerators was fitted with a powerful gas burner. The effect of these burners was felt at once. Instead of the refuse being difficult to deal with, and causing great annoyance, it was very quickly burnt, and with practically no smouldering.

In this portion of the Exhibition are the living quarters of the natives. They are located in wooden huts; and the Brentford Gas Company have carried-down a supply of gas, to do some of the necessary cooking for them. The plant has been installed here by the Gas Light and Coke Company, under the supervision of Mr. Smithers.

Chinese Restaurant.

The gas equipment of the Chinese Restaurant in the Hong Kong Section was also installed by the Gas Light and Coke Company; and for this again Mr. Smithers was responsible. It consists of three large hotplates specially designed to meet the requirements of the Chinese cooks, a small hotplate, a "Regulus No. 1" cooker, and two gas-heated coppers. The necessary hot water for washing-up purposes is provided from a Ewart "Califont" geyser, and water is supplied by a gas-heated boiler by Messrs. John Harker & Co. There are also small vegetable steamers by Summerlings. The supply is through a 100-light meter off a 2-in. service.

The City of Bath utilize gas to illustrate their natural hot springs, for which Bath is so well renowned. The water is heated by means of a "B.T.U." boiler, and a thermostat is used so that the temperature of the water is the same as that available at Bath. In practice the boiler is found to carry out the work of throwing up and circulating the hot water in a very efficient way.

I have already, in a previous article, described the new kitchen of Ceylon. In addition, the two old kitchens will be used for cooking. There are two Keith & Blackman water-boilers, Still boilers for tea making, and a small hotplate in each of the kitchens.

In South Africa a new restaurant is being installed. There are a Keith & Blackman circulating boiler, a hotplate fitted with the self-cleansing burners, Still boilers for the necessary boiling water, and Still grills for toasting scones, &c. It is supplied off a 2-in. service and 100-light meter.

The Stadium.

In the Stadium, through the tunnel, a 6-in. supply is carried, connecting with a 4-in. main which supplies the Stadium kitchens. The Stadium restaurants are being run this year by the Dominions Catering Supplies, Ltd. The main restaurant has a very large dining hall. There are kitchens at each end, and a 300-light meter with 4-in. connections is installed in each. They have double-tiered salamanders, a large gas-heated hotplate, gas-heated hot closets, large "Falcon" roasters—these are of particularly large size—a gas-heated fish frier, three Still

ENGINEERING WEST (MESSRS. PRITCHARDS).

PALACE OF INDUSTRY EAST.—A.B.C. KITCHEN, SHOWING FISH FRYER, GAS OVENS, AND SALAMANDERS.

oiling burners for the necessary boiling water, a number of as-heated milk urns, and a large gas-heated toaster and egg oacher combined, of the pattern used by Messrs. Lyons.

There is a 4-in. main right round the Stadium. This is fed rough the 6-in. main already referred to; and there is a 4-in. ain on the other side of the Stadium.

Around the Stadium there are eight buffets. These are fitted ith Still boilers for the necessary boiling water, and Keith-Blackman circulating boilers for the hot water for washing-up lasses, cups, &c. The whole of the buffets are fitted in identically the same way.

The New Café is supplied by means of an 80-light meter off 3-in. service. Here there is a Wright's "Eureka" cooker, ve boilers for the necessary boiling water, a gas-heated hot loset and milk urns, and a large hotplate with four Keith-Blackman burners. This café is run by MacFisheries.

A new departure is a Gentlemen's Hairdressing Saloon. The ecessary hot water is supplied by a Ewart's "Radion" ylinder.

In close vicinity to this saloon are the new premises of the t. John Ambulance Brigade. The Brentford Gas Company ave fitted-up gas fires here, so as to ensure the necessary armth in case of accidents or any emergency.

The Alderman Café is supplied by an 80-light meter off a -in. service. It is fitted with a large Keith & Blackman hotlate, gas-heated egg boilers, three Fletcher Russell toasters, ve Still boilers, and a number of gas-heated milk urns; also Wright's "Eureka" cooker.

Each of the catering firms has an Administration Office, to acilitate the necessary control and supervision of their organiations. To each of these a gas supply has been run. In these remises the pasteurization of milk is carried out, which is then istributed to the various cafés, buffets, &c.

There is a South-West Institute for the Exhibition employees. his is installed with gas appliances in the same way as the Vorth and South-East Institutes.

West Africa.

Messrs. Buchanan Scott, Ltd., are doing the catering in West frica. There is a Still boiler for the production of hot water, Keith & Blackman circulating boiler for washing-up purposes, hotplate fitted with the new self-cleansing burners, and a No. 1 "Regulus" cooker. This is supplied by a 150-light neter off a 3-in. service.

In Nigeria there is a 300-light meter installed, for running large Spencer-Bonecourt boiler. The evaporating power of his boiler is 3000 lbs. per hour. The power will be used for rushing nuts and extracting oil. There is a 4-in. supply.

The Indian Restaurant is being run by Messrs. Veerasawmy. t is fitted with three "Regulus" cookers, three large Keith & Blackman hotplates and double-tiered toasters, two Cox grills, a large gas-heated hot closet, additional boiling rings, &c., together with a 4-panned fish frier. This is supplied by a 200-light meter with a 4-in. supply. The boiling water is supplied by Still appliances.

Engineering and Industry Restaurants.

The Engineering East Restaurant is being run by the Haymarket Hotels. The supply is through a 400-light meter; and here again there are gas-heated fish friers, batteries of Cox grills, Wright's "Eureka" stove, Keith & Blackman boiling rings, salamanders, and toasters, and Still boilers for the production of the hot water. In the kitchen above is a similar equipment, with additional large roasting ovens and gas-heated egg poachers.

In the Engineering West Restaurant there is the usual equipment of a large kitchen—toasters, hotplates, Cox grills, egg poachers, fish friers, and two Portway "Tortoise" stoves. This stove is spoken of very highly by Messrs. Pritchards, who are running this restaurant. They say that they have had these stoves in operation in other of their branches, and they have given great satisfaction. The kitchen above is similar, and shows practically the same apparatus. We show a photograph of the stove referred to. A 400-light meter is fitted here with 6-in. supplies.

In the Industry East Restaurant, which is being run by the Aerated Bread Company, there is a 400-light meter and 4-in. supplies. They have installed two Richmond large roasters, a Keith & Blackman hotplate, a large fish frier, gas-heated carving tables, batteries of Cox grills, Still boilers, gas-heated milk urns, hot closets, &c. The kitchen above and the Palace of Industry West Restaurant are practically identical.

Children's Welfare.

With regard to Children's Welfare, it might be advisable to mention the preparations made for the reception of children who are lost in the Exhibition and require care. For this they have installed gas fires. An Edgar geyser supplies the necessary hot water for emergencies, and gas-heated appliances are fixed for cooking any food required.

The Domestic Grate.

Technical Paper No. 13 of the Fuel Research Board has just been published. Entitled "The Domestic Grate," this is an account of an investigation, by Dr. Margaret W. Fishenden, of the relation between the design of a grate and the heat radiated into a room. In a brief summary the author states that the following are important factors in the efficient utilization of open fires for warming purposes: (1) The use of correctly-designed grates, properly fitted, in order that the maximum possible proportion of the radiation emitted by the incandescent fuel may be directed into the room; (2) the provision of adequate draught control, so that not only may the fire be rapidly adjusted to meet varying requirements, but also the air flow through the room be reduced to the minimum consistent with the demands of hygiene and comfort; and (3) efficient insulation of the room, so that the temperature rise effected by a given energy input may be as great as possible. Dr. Fishenden mentions that the very gradual rise in temperature which an open coal fire induces in a room is one of its most serious drawbacks, especially for intermittent use. It is just during the period immediately following the kindling of the fire, when the room has not yet had time to get warmed-up, that a maximum amount of radiation is needed for comfort; and actually, at this stage, the fire is giving a minimum radiation emission. It is stated that it is doubtful whether the radiation efficiency of open coal fires against a wall can easily be increased beyond 30 p.ct. or 35 p.ct. of the theoretical energy of combustion. The publication is obtainable from H.M. Stationery Office, Adastral House, Kingsway, W.C. 2, price 9d. net.

THE GAS EXHIBIT.

There is evidence of the bestowal of great thought and much work on the British Empire Gas Exhibit, 1925—and thought and work of a kind that will be abundantly rewarded, given the fine weather that should spell huge attendances at Wembley. There is no need to compare this year's display with the excellent and thoroughly successful effort of 1924; but it is manifest that certain circumstances have favoured the present occasion. For one thing, there is available considerably more ground space, which has been taken advantage of to provide, for one thing, a separate Demonstration Hall, in which a knowledge of cookery, and of the efficient use of gas for the purpose, will be imparted to those desirous of acquiring it under conditions of greater comfort than were possible last year. And in planning the 1925 exhibit, of course, those responsible have had the experience of 1924 to guide them in the fixing-up of various details. In addition to this, the Committee, by good fortune, have had the opportunity, as explained towards the end of the following account of the exhibit, of introducing this year two special features which must make a wide appeal.

Gas is again worthily represented at Wembley, and for this the gratitude of the industry is due to Mr. D. Milne Watson (the Chairman) and the members of the British Empire Gas Exhibit Committee, to Mr. F. W. Goodenough (Chairman of the Executive Committee), to Messrs. J. E. Henwood and J. C. Walker (Joint Hon. Secretaries), and to Mr. A. E. Broadberry (the Hon. Treasurer). Mr. H. Austen Hall, F.R.I.B.A. (Architect to the Committee), has again given of his best; while the work of the contractors (Messrs. Osborne & Co.) has left nothing to be desired.

The Exterior.

Approaching the Gas Exhibit by way of the familiar avenue through the Palace of Industry, one is immediately influenced by the appealing nature of the exterior. This is a good thing; for everyone knows the importance of first impressions. And the favourable impression being made, further investigation will surely follow.

There has been painted as a background to the whole of the front of the building a very artistic view of a gas-works—not such a picture as is too often associated with a gas-works in the minds of the public—and the whole of the space on the outside has been given over to industrial exhibits. This imparts the atmosphere of life and movement which experience has shown to be so important in connection with displays to attract the close attention of the general public.

Last year, it will be recalled, there was on the one side of the main entrance to the Gas Pavilion a smoke abatement exhibit, and on the other a sulphate of ammonia display. Both these proved exceedingly popular—particularly from an educational point of view—but it was felt, nevertheless, that the smoke abatement exhibit especially, convincing and well arranged as it was, lost considerably in effect from the magnitude of the Palace of Industry under whose spacious roof it was placed.

Therefore, in that space—*i.e.*, on the east side of the porch—there have now been placed a big gas engine of 180 H.P. over 9 ft. high, and a smaller one of only 20 H.P., each illustrating the use of gas for power. Adjoining these is a 10-ft. long gas-fired travelling oven, showing wafer or biscuit baking in actual operation.

On the other side of the porch, where formerly was the sulphate of ammonia exhibit, the many applications of gas to the motor manufacturing industry are demonstrated, and emphasis given to the value of benzole as a motor spirit. The space is "flood-lighted" by high-pressure gas lamps installed on "benzole roadside pumps" in lieu of ordinary columns—the necessary pressure being afforded by the motor engine that is shown being "run in" by gas, which is more economical for the purpose than petrol or benzole. There are here, in addition to the chassis of a motor car, all the appliances in which gas is used for making the parts of the car.

Overseas Dominions Hall.

Having seen so much of general interest on the outside, the visitor will wish to examine the further attractions that he will feel convinced await him on the inside. Entering through the porch between the two exhibits just referred to, he will find himself in what has been named the Overseas Dominions Hall; and there will be no desire to leave it before a thorough inspection has been made of the contents.

The great point that the British Empire Gas Exhibit Committee are wanting here to bring home to people is that gas is still a vigorous and growing industry, which is, in fact, increasing in activity day by day, not only here but in other parts of the world; and hence they have, by means of the display in this hall, linked-up the industry with Overseas. The result will interest everybody, and will serve to remove from that portion of the public mind which still harbours it the idea that the gas industry is simply carrying on in the Old Country because it was started there, and is not making headway elsewhere. The true position is, of course, that the gas industry is "going strong" throughout the Empire's wide Dominions. There are, indeed, some 200 undertakings which manufacture gas in Australia, New Zealand, and Canada alone; and their business is steadily growing in dimensions. This last remark does not even exclude Canada, where electricity is extraordinarily cheap.

To press home the point they had in view, the Committee have illustrated in the Overseas Dominions Hall—which is, it must be unnecessary to say here, throughout lighted by the most efficient and artistic gasfittings—the multifarious service of gas in the homes of the Empire; but the apparatus shown is all of a type equally suitable for homes in the Mother Country. City scenes in the Dominions Overseas have naturally been chosen; and it is well known that the more luxurious homes in those Dominions mostly show a marked English influence. This will make the exhibit thoroughly practical from the point of view of the use of gas in this country. Each corner of the hall is occupied by a domestic scene from one of the greatest Overseas Dominions—Canada, Australia, South Africa, and India—and across these corners are the coats of arms of the Dominions, modelled in plaster and brilliantly coloured.

Canada.—The Canadian scene depicts an entrance hall, and shows gas-heated radiators supplemented by a gas fire in one corner of the room. Out of this hall will be found a "Kitchenette" showing the arrangements and equipment for cooking purposes in the average Canadian home. Everything is close to the hand of the cook, and the gas cooker is of the most modern type—raised so that no stooping is necessary, and provided with an automatic heat regulator, &c. From the window of the hall can be caught a glimpse of a typical Canadian landscape.

Australia.—In the opposite corner Australia is represented by a delightful children's nursery, the windows of which reveal the famous view of Sydney Harbour. Out of the nursery opens the children's bath-room—a very attractive place for the youngsters, with strange fishes depicted on the tiles around the upper half of the room. The bath itself is slightly sunk. This scene, of course, displays gas water-heating apparatus.

South Africa.—The South African tableau depicts an old Dutch-interior sitting room, with the brick fire-place adapted for use with a gas fire. The furniture is typical old Dutch hard wood; the seats of the chairs and settee being composed of strips of hide.

On one side of this sitting room is a kitchen or "still room," where fruit bottling will be in constant operation. Although this is next door to South Africa, it is not intended to link it too definitely with that country, since both Australia and Canada have large fruit-bottling industries; and, by means of publicity matter, this scene can be connected with all three Dominions.

India.—India shows a bathroom with a gas water heater and a pantry next door with a refrigerator operated by gas, providing small blocks of ice convenient for use in drinks, and ice creams and other forms of set dishes, as well as the cold storage so essential in the climate of India. On the other side of the bathroom has been arranged a strip of verandah, where the dummy figure of a native seated illustrates the brilliantly coloured materials so beloved of the natives, which owe their colouring to the dyes obtained from coal tar.

New Zealand.—The remainder of the space on one side of the hall is occupied by a tableau representing New Zealand. This consists of a luxurious bedroom and boudoir, the window of which look on to beautiful typical New Zealand scenery.

A Pioneer's Store.—On the opposite side of the hall there is the interior of an up-country store, such as the pioneer depends upon in every Colony or Dominion. The contents of this serve to illustrate the manifold resources and uses of the gas industry—the whole of the stock being either bye-products of the gas industry, such as disinfectants, drugs, fur preservatives, sheep dip, &c., or articles in the manufacture of which either gas or one of the many bye-products of gas making is habitually used. This exhibit will prove excellent for emphasizing the wide spread use in industry of gas and its bye-products.

The cabin has not been linked-up with a particular Colony because it may apply to any one.

Gas Fire Exhibits.

In the centre of the Overseas Dominions Hall are three hexagonal pylons as last year, each showing six different types of gas fire in all kinds of suitable fireplace surrounds, varied from those shown in 1924.

The decoration of the hall itself is in white; and the ceiling consists of cream-coloured gauze stretched over batons—the general effect aimed at being that of a more sunny climate than is usually experienced in this country.

A Luxurious Lounge.

A charming Queen Anne period lounge has been arranged in the space which joins the hall just described and that to which reference will now be made. It is handsomely panelled

and opportunity has been taken to display a very fine gas fire of appropriate design.

The Hall of General Exhibits.

Entering from the lounge the second hall—known as the Hall of General Exhibits—and turning to the right, there is found first a garage and chauffeur's workshop, illustrating the applications of gas to the heating and lighting of a private garage by means of safety gas-heated radiators and safety gas lamps, and the uses of gas for brazing, vulcanizing, &c.—so helpful to a chauffeur-mechanic. Next to the garage are the chauffeur's parlour-kitchen and scullery, fitted with a gas cooker, gas-heated copper, water heater, iron, a gas fire, and, of course, gas lighting fittings.

Smoke Abatement Exhibit.

On the opposite side of the Hall of General Exhibits the chief feature is a smoke abatement exhibit, consisting of two rooms identical in decoration and furnishing—the one showing a coal fire polluting the atmosphere with smoke and making everything inside the room dirty, while the other demonstrates the scientific use of coal (by its treatment at the gas-works, and the distribution of its purified "spirit" in the form of gas) and the cleanliness and brightness that would be our heritage if open coal fires were unknown in London.

By means of theatrical lighting effects, the windows of the first room look-out on a foggy scene, and those of the second room on to a nice clear sky.

Gas for Various Purposes.

The Greenhouse.—Next to the smoke abatement exhibit is a greenhouse heated from without by a gas-fired boiler, and containing an attractive display of flowers.

The Shop Window.—Adjoining this greenhouse, and flanking the northern entrance to the exhibit, there will be found a shop window showing effective gas lighting of such premises, and containing an interesting display (suitable for a gas company's showroom window) illustrating the many bye-products of different kinds obtained from the carbonization of coal, but lost if coal is burned in open grates.

The Domestic Laundry and All-Gas Kitchen.—On the other side of this entrance, there has been erected a working domestic laundry suitable for a large house or private hotel, and alongside it a model all-gas kitchen suitable for such a house.

The Hotel Kitchen.—Opposite to this is a complete hotel kitchen containing gas apparatus suitable for every description of cooking.

In the space where the cookery demonstrations were held last year, a number of armchairs for the comfort of the public have been placed.

Converted Coal Grates.—The central space in this hall, which was in 1924 taken up by industrial working exhibits, is this year occupied by a demonstration of how gas fires can be installed in front of existing coal grates, so as to make a harmonious heating unit.

Hobbies and Pottery Making.—There is also a working display demonstrating how gas is applied to many hobbies; and a very interesting show of pottery-making by the disabled ex-Service men employed at the Ashtead Pottery.

Lecture and Demonstration Hall.

Beyond the west end of the Hall of General Exhibits has been provided—and it will certainly be regarded as a great improvement upon last year's arrangements—a separate quiet hall 50 ft. square, which will be devoted to frequent practical lectures and demonstrations for the assistance of housewives in securing the most efficient and economical results from the use of gas, not only for cooking, but also for all other domestic operations involving the use of heat or light. Around this Demonstration Room will be found a selection of the most up-to-date gas cooking, water heating, and other catering appliances; and also a very interesting installation of gas-heated fish-frying apparatus, which is becoming popular in the trade.

The present arrangement has, of course, enabled a lot more apparatus to be put in than was possible last year—which should lead to the enhanced satisfaction of all concerned.

A Coke Exhibit.

A space between the Demonstration Annexe and the main gangway has been taken by the Gas Light and Coke Company, who are making, at their own cost, a special display of coke appliances, mainly for domestic use.

Here are to be seen an artisan's kitchen, a model kitchen, and a bathroom, showing different types of open grates using coke, and an anthracite stove running on coke, as well as several types of coke boilers, both working and otherwise. Here are shown in use the different sizes of coke suitable to the varying requirements. In fact, it is convincingly demonstrated that coke can displace coal for any domestic purpose.

Prof. Boys' barless grate for the consumption of coke is on view, as are also some models of industrial appliances for use with coke.

The Side Gangway.

Along the side gangway are exhibits of gas appliances for use in various industrial processes, together with samples of the finished products in the making of which gaseous fuel is employed. These appliances include furnaces, crucibles, ovens, and blow-pipes of all descriptions. The finished products comprise motor gears, false teeth, printers' type, pea nuts, toy soldiers, engravers' dies, buttons, tools, aluminium castings, pottery, rivets, sweetmeats, varnished toy models, feathers, glass bulbs, telephone magnets, &c.

Empire Food Stuffs.

Since arrangements were made for a separate Demonstration Hall, a Special Committee for organizing propaganda for

A SCENE IN THE GAS EXHIBIT ON SATURDAY.

[Other Photographs of the Completed Exhibit will appear in Succeeding Issues of the "Journal."]

increasing knowledge and use of Empire Food Stuffs in the Home Country (presided over by Lady Galway, who is Chairman of the Executive of the Women's Section of the B.E.E.) have asked for the assistance of the British Empire Gas Exhibit Committee in the matter of lectures and demonstrations in the Cookery Demonstration Hall on the purchase, preparation, and cooking of Empire Food Stuffs. The Gas Exhibit Committee have agreed to lend the hall and to provide the lecturers and demonstrators—who will be furnished with all necessary information by the Empire Food Committee—and to arrange, in consultation with the Empire Food Committee, a programme of daily lectures and demonstrations to fit in with those already being planned on gas cooking and other aspects of domestic economy in which gas plays an important part.

The Gas Exhibit Committee will exercise full control over all plans. The Women's Section of the B.E.E., in conjunction with the Gas Exhibit Committee, will arrange for widespread publicity, and for well-known men and women, both from the Home Country and the Dominions, to take interest in the scheme, as well as for their frequent attendance to preside at lectures, give receptions, and otherwise show their sympathy with the movement. H.M. The Queen is Patron, and H.R.H. The Duchess of York is President, of the Women's Section.

Society of Women Journalists.

Inquiry was lately made by the Society of Women Journalists as to whether it would be possible for the Gas Exhibit Committee to afford women journalists visiting Wembley—not only from London, but from the Provinces, and also from the Dominions and Colonies—some accommodation for rendezvous, rest, writing, &c. The Committee immediately offered, and the Society gratefully accepted the offer, to fit-up for their use as a reception bureau a suitable room in the offices that had been constructed behind the Demonstration Hall. This room has been furnished free by Messrs. Osborne & Co.

Upon this special feature, and the arrangements that have been entered into in connection with Empire Food Stuffs, the Gas Exhibit Committee should be particularly congratulated; for they must result in making the exhibit a centre of interest for all women visiting Wembley, and at the same time ensure an exceptional amount of publicity.

BRITISH ROAD TAR EXHIBIT.

National Gas Council Display.

[*See Illustration on p.* 465.]

"British Tar for British Roads" would seem to be the slogan of the road tar producers who have organized a display at Wembley. The initiative has been taken by the National Gas Council, who acquired 1500 ft. of space in the Chemical Section of the Palace of Industry for an exhibit which will constitute the starting-point of a campaign designed to extend still further the use of tar in road construction and road maintenance. It is confidently anticipated that all the tar producers in the country will co-operate in pressing forward the good work which the National Gas Council have thus inaugurated.

The exhibit, which has been designed by the well-known artist, Mr. Norman Wilkinson, shows a wayside inn, which has been very appropriately named "The Jolly Jack Tar," with a tar-macadam road circumscribing it in front, passing over a bridge, and going off into the background. It is altogether a delightful little scene, which will receive its meed of praise from every passer-by. The artist has admirably fallen into line with the whole scheme of an exhibition in which, as is officially pointed out, "working models and scenic effects take, in large measure, the place of stacks of raw materials." In "Canada," "Australia," and "New Zealand" there are jewels of this kind which will long remain in the mind's eye; and "The Jolly Jack Tar" will have a place among them.

The Council propose to invite surveyors, chairmen of highways committees, road constructors, and others interested, to visit the stand, and to discuss with the expert in attendance any problems of a technical nature which confront them.

It is felt that in the past the economic and practical uses of British coal tar have not received the attention they deserve; and recognizing this, it has been decided by the producers to go carefully into the question from every aspect. It is intended to conduct a thorough investigation into every phase of construction work wherein coal tar enters.

Association of Statutory Inspectors of Gas Meters.—The annual general meeting of the Association (whose President is Mr. H. N. Barrow, J.P., the Chairman of the Manchester Justices' Gas Meter Testing Committee) will be held in the new County Hall, Westminster, on Wednesday morning, June 10, when the report of the Council will be considered and the general business transacted. By permission of the London County Council, and with the assistance of the Vice-President (Mr. J. Ollis), the afternoon will be devoted to a visit to the Finsbury gas meter testing office. Members will assemble at the office in Helmet Row, Finsbury, at 2.30.

WOODALL-DUCKHAM MODELS.

A Good Display in the Chemical Hall.

Among a number of models in the Scientific Section of the Chemical Hall, in the Palace of Industry, is an interesting collection loaned by the Woodall-Duckham Vertical Retort and Oven Construction Company (1920), Ltd., to illustrate modern means that have been adopted for treating coal and some of its products.

There is an extraordinarily complete and up-to-date model of a Woodall-Duckham vertical retort installation. This shows the latest silica construction, with two-stage heating, largely by which means the Woodall-Duckham Companies have been able to increase the thermal yield per retort by approximately 50 p.ct.

There is also a model of the most recent intermittent vertical chamber system. This model, as well as that of the chamber oven, is of quite a novel type. Every detail of operation, mechanism, and machinery is indicated; and nothing could be better than this method of presentation, on a small scale, of the system.

The model of the inclined chamber oven, another system which is also handled by the Woodall-Duckham Companies, is similar in conception to the intermittent vertical chamber model. These chamber ovens are particularly applicable to large works, where dense, blocky coke is desired, and where difficult coals only are available. In fact, the chamber oven may be taken as a substitute for large-scale horizontal practice, in that labour costs are materially reduced as compared with horizontals.

Another model of great interest is that of the "T.I.C." (lead bath) complete tar distillation plant. This is to scale; and the "attendant" in charge of the plant is also to scale. The model is complete with stills, condensers, heat interchangers, furnaces, receiving bunkers, pitch bays, railway tracks, and receiving trucks.

A brickwork model shows various sections of the latest type of Becker oven, and the cross-over flues which enable the coke ovens to be built longer and higher than was previously possible. In these ovens blast furnace coke, domestic coke, or free-burning smokeless fuel can be made at will. The throughput of coal per day may be as high as 25 tons per oven.

The Carpenter centrifuge—an apparatus for drying wet coals—is exhibited in model form. The most recent plant installed in this country is reducing the moisture to 5 p.ct., has a capacity of 50 tons of coal per day, and a power consumption of less than 1 H.P. per ton of coal treated. We understand that there is a big demand on the part of the collieries for these driers.

There are a number of excellent coke sections prepared by the research branch of the Woodall-Duckham Companies, to illustrate the structure of solid smokeless fuels made in different ways. Each of the models shown by the Companies is accompanied by one or more large framed photographs of the models, on which are indicated the names of the different parts of the plants. These photographs will prove of great value to the uninitiated.

Further, the Woodall-Duckham Companies have loaned to the Chemical Section forty mounted photographs, which form a sort of picture gallery illustrating the complexity and ramifications of the gas industry. These photographs are representative of the industry in all parts of the country.

There is no hesitation in saying that a close examination of this collection of models will repay those interested in carbonization.

Gas for Wicker Furniture Making.

The claim is advanced in the columns of the "American Gas Journal" that gas-fired boilers have done more to make reed and wicker furniture popular than any other one thing. Gas heats the water in which the dowels, or round pieces of rattan, ash, birch, or other wood are soaked to make them flexible. The reed pieces are then gone over with a gas torch, which singes off the fuzz; and the next operation is to place them in high-pressure steaming ovens, gas heated, where the dowels are rendered so flexible that they can be twisted and wound in any shape desired. The use of gas not only increases the speed of production, but reduces breakage to a minimum, and entirely eliminates cracking or warping in the finished product, as the high steam pressure forces the moisture on the outside of the dowels into the cells of the wood, and thus renders it extremely flexible. Wicker furniture manufacturers say that the introduction of gas fuel in the singeing and steaming operations has enabled them to keep pace with an enormous public demand for their product.

Preparing a Tender.—The Society of Engineers have published in pamphlet form (price 3s., post free) a paper entitled "Notes on Preparing a Tender," by R. I. Money, M.Inst.C.E. This lengthy paper contains some valuable data, and will prove very useful to engineers.

GAS AND THE HOUSING PROBLEM.

The Palace of Housing and Transport.

Reference was made by the King, in his speech at the opening, to the fact that this year one of the great halls—it is the one which last year constituted the Palace of Engineering—has been devoted to exhibits illustrating those problems of housing and transport which call so urgently for solution. It will be found that the principal section of what has thus now become the Palace of Housing and Transport is devoted to a collection of model houses, built with all the latest improvements known to science. Set out in tempting array, with gardens containing flowers and shrubs, are houses of timber, houses of brick, houses of steel, houses of timber and steel, houses of steel and concrete, and houses of concrete alone.

For this Housing Section, it is safe to prophesy great and lasting popularity. It deals with a problem that is in the minds of all at the present juncture; and it deals with it in a manner that must be productive of good. It shows that houses which are a pleasure to the eye so far as the exterior is concerned, and comfortable in the interior beyond all possibility of comparison with many of the old-style houses of similar size and class, can be provided without difficulty from the material point of view, if other obstacles are removed. There is plenty of room in the Palace for the various buildings to be seen in proper perspective, which is, of course, a highly important consideration in connection with exhibits of this character. However, of the general lay-out of this part of the exhibition it is impossible to say more here. Our special interest in the section at the moment centres on the displays mentioned below.

"Century" Houses.

Occupying a prominent position in the Palace of Housing will be found a pair of "Century" houses, of the shingled type, constructed by Messrs. Henry Boot & Sons (London), Ltd., of No. 12, Grosvenor Place, S.W. Scientifically planned and executed in substantial style, these houses are provided with a living room, scullery, bath room, lobby, and the usual conveniences, on the ground floor, and three bedrooms; and the British Commercial Gas Association have been instrumental in arranging an appropriate and highly effective installation of gas apparatus. The lighting points, by means of Bland Light Syndicate fittings, have been arranged so as to demonstrate good illumination combined with efficiency and strict economy. There are one-light pendants with silk shades, and the feature of this portion of the exhibit is the fact that the illumination is arranged to correspond with the natural lighting. The pendants are fitted 2 ft. 6 in. back from the windows in the bedrooms, as this position provides the best light for a woman making her toilet.

From the fuel consumption point of view, the houses are smokeless throughout. In the scullery, there is in one case a Messrs. R. & A. Main's "Maintop," and in the other a Radiation "New World Junior" cooker. The wash coppers are respectively by Messrs. Wilsons & Mathiesons and Messrs. John Wright & Co. In the bedrooms there are built-in gas fires, with cast-metal registers complete, supplied by the Davis Gas Stove Company, Messrs. Fletcher, Russell, & Co., the Parkinson Stove Company, and Messrs. John Wright & Co.

"Solignum" wood-preserving stain is used here.

"Solignum" House.

While speaking of "Solignum," mention should be made of a charming little house in the Palace, which is occupied by Messrs. Major & Co., the proprietors of this extensively used wood preservative, and in which they draw attention to its many advantages.

A Gas-Fitted Bungalow.

An attractive bungalow has been fitted out by Messrs. Hampton & Sons, Ltd., of Pall Mall East, London, S.W.; and in this there are demonstrated up-to-date methods of hot water supply and cooking. For the former there has been installed by Messrs. Thomas Potterton, of Cavendish Works, Balham, S.W., a "Victor" No. 931 complete apparatus, so arranged as to afford an example of hot water service throughout the bungalow—supplying the bath, sink, and hand basins, and operating in conjunction with a No. 1 "Domestikatum" boiler, airing coil in the linen cupboard, and nickel-plated towel dryer in the bathroom. The No. 1 "Domestikatum" boiler forms an excellent combination with the "Victor" gas boiler, for alternative use in suburban and country residences, where access to the fuel store is easily arranged.

The cooking equipment of the bungalow is represented by a "Chef" series stand model gas cooker, by Messrs. William Sugg & Co., of Ranelagh Works, Westminster, S.W., as an example of efficient apparatus for this purpose.

Mr. John Graham Stewart, of Dunblane, Chairman of Messrs. Stewarts and Lloyds, Ltd., tube manufacturers, who died in March, aged 63 years, left personal estate in England, Scotland, and abroad of the value of £396,753.

GENERAL EXHIBITS.

"W.-D.-C." Gas-Fired Boiler Burner Equipment.

An exhibit by Messrs. Burnard in the Palace of Industry consists of a complete milk sterilizing plant, and in connection therewith is a Woodall-Duckham-Cochran gas-fired boiler, fitted with the burner equipment of British Furnaces, Ltd., whose head office and works are in Derby Road, Chesterfield.

The Cochran boiler is of an ideal design for the purpose of incorporating the principles of surface combustion, and in the "W.-D.-C." gas-fired boiler these principles are applied. The usual grate for coal firing is replaced by a bed of broken refractory material, and into this bed is delivered a correctly proportioned mixture of gas and air. Combustion is instantaneous and complete, and the bed rapidly attains a state of incandescence.

The burner consists of a heavy casting set in brickwork, and so arranged that only a minimum of surface is exposed to, and can absorb heat from, the furnace. A sufficient cross section is provided to conduct back to the outside of the furnace the heat so absorbed. In this manner, the tip or nozzle is automatically kept uniformly cooled. The burner is supplied with a correctly proportioned, and thoroughly homogeneous, mixture of gas and air through a surface combustion proportioning inspirator. These inspirators automatically maintain constant and correct proportions of gas and air in the mixture fed to the burner, and they further make it possible to control the quantity of mixture by means of a single valve. Independent means are provided for setting the air-gas ratio.

The advantages claimed for the "W.-D.-C." gas-fired boiler are: Guaranteed high efficiency (up to 90 p.ct.); perfect and flameless combustion; automatic proportioning of gas and air; back-firing and explosions eliminated; no excess air in products of combustion; no brickwork setting required; no induced draught; dry steam; minimum floor space; radiant heating; and automatic control easily applied.

"Ideal" Domestic Boilers.

In the Housing Section a good show is made of "Ideal" domestic boilers, which, it is pointed out by the makers—the National Radiator Company, Ltd., of Hull, and Nos. 439 and 441, Oxford Street, London, W.—are simple in design, yet highly efficient; 50 gallons of hot water being obtained with 9 lbs. of coke. They occupy little space when installed, and are easily connected to existing pipes, as auxiliary to, or independently of, the kitchen range boiler; and they are, of course, of great use accompanying gas cookers. Both closed and open-fire patterns are manufactured, so as to meet all requirements. The "Ideal Classic" boiler is designed for central heating systems, and enables from three to ten rooms to be warmed from a single fire, at the same time providing abundant hot water for baths and domestic use.

Asbestos for Engineers.

Bell's United Asbestos Company, Ltd., who are represented in the Palace of Transport, were the first to engage in the European asbestos trade, having been established in the year 1871. All asbestos goods sold by the Company are made at their own works; and the Company are therefore able to secure for their products a uniform standard of excellence.

"Monometer" Specialities.

Again this year there are to be seen examples of the specialities of the Monometer Manufacturing Company, Ltd. In the Palace of Transport attention is drawn to their white metal furnace for use with gas, as well as to their patent low-pressure gas die-casting machine. Those connected with the printing and allied trades who go to Wembley will doubtless take the opportunity of inspecting this exhibit, which is likely also to receive the consideration of gas men. To the white metal user the appliances present various features which deserve to be taken into account; while the gas man will regard them as useful media for securing an addition to the highly desirable "industrial load."

Pasteurizing Milk by Gas.—If you cannot obtain pasteurized milk, and if you are doubtful about the purity of the raw milk, you may pasteurize it at home on the gas cooker hotplate by the following easy methods set out in the "American Gas Journal": Take a pail deep enough to allow water placed in it to reach the neck of a quart milk bottle. Place an inverted saucer in the bottom of the pail, and set the bottle of milk on the saucer. Pour water into the pail up to the top level of the milk in the bottle. Put the pail containing the bottle and the water on the hotplate, and leave it there until the water boils. Then turn off the gas, remove the pail, and let it stand, covered, for half-an-hour. Remove the bottle of milk, and cool it quickly by letting cold water run over it. Boiling the milk for three minutes will also make it safe for infant feeding.

NEW GAS SHOWROOMS AT HULL.

Enterprise of the British Gas Light Company, Ltd.

The new showrooms of the British Gas Light Company at Hull are generally admitted to be, for beauty and completeness, in the very front rank of such contributors to the service of gas undertakings. Attestation to this is given by the series of photographs which we are enabled to publish this week through the courtesy of the Company's Engineer and Manager at Hull (Mr. Harold E. Copp).

The showrooms occupy an important corner site in the centre of the city, and have a window frontage of approximately 180 ft. There are two entrances, one in Story Street and one in Prospect Street. The main entrance hall is in Story Street, and is 45 ft. long by 15 ft. wide. On the right, as one enters, is the Showroom Manager's office, the accounts and cash sales office, and the service and complaints office, while beyond this is a model room, the idea of which is to display suitable gas apparatus for heating and lighting to suit the particular furnishings shown. To the left is seen the ground-floor showroom, the salesmen's desk (where all sales, &c., are recorded), and the seating accommodation provided for consumers. Here also is

Entrance Hall.

A Corner of the First Floor.

Combined Showroom and Rest Room.

Another Showroom with Bathroom Annexe.

shown a coke fire in operation, constructed on Prof. Boys' principle, and lighted by a gas poker burner. This has attracted considerable attention, and has stimulated the sale of coke for household use.

The display of lighting fittings on the ground-floor is also an attractive feature. The showrooms on the first-floor are beautifully arranged, and are interconnected by archways.

A pneumatic tube has been installed, connecting the cashier's office on the ground-floor with the general offices in Baker Street, situated about 380 yards distant. Cash and receipts are passed directly through the tube between these points, and the carrier only occupies about 18 seconds in transit. One of the illustrations shows the room at the top of the staircase. This is a showroom and rest-room combined, being tastefully arranged, light, and airy. The centre-well provides adequate ventilation and light.

Another photograph portrays a showroom in which are a model bath, a gas-heated towel rail, a geyser, and a "B.T.U." circulator, together with glass show-cases containing silk shades, gas brackets, and glassware. Here also are shown gas fires in suitable fireplaces, "Eye-Level" cooking ranges, &c.

A portion of the gasfittings display room and the costing office counter are depicted in a further illustration. The beauty of the arches and architectural work generally will be noted in the various photographs.

On the top floor a lecture room has been provided which will seat about 120 people, and cookery lectures are already proving themselves a great source of attraction and interest. Stock rooms and a test room have also been fitted on this floor. All floors are reached by a lift.

The Architect for the work is Mr. P. Morley Horder, F.R.I.B.A., of London.

In the handsome new building, cookery lectures and demonstrations have been revived; and the opening lecture was delivered by Mrs. Dunn on April 20. On the occasion, Mr. Copp stated that the primary object of the lectures was service to the community. The British Gas Light Company, Ltd., he said, instilled into the minds of their officials the idea that they were the servants of the public, with obligations and responsibilities to their consumers. In London, Paris, and New York—especially in the last-named city—there was an enormous increase in gas consumption for domestic purposes. One could not help feeling that in this country cookery had been neglected; and it was with the idea of securing an improvement in this direction that the lectures were being revived.

Mrs. Dunn, who has been on the staff of the British Gas Light Company for many years, is an interesting demonstrator, and there are no dull text-book references in her lectures. Her audiences (on the occasion of the first lecture, as on others) made profitable use of notebooks and pencils, and were in general agreement that a simple recipe and an ordinary gas cooker could in combination achieve delectable results in pastry making. The lectures occupy about one hour, and are held in the afternoons.

Gasfittings Display Room.

Lecture Room.

HOUSE HEATING.*

It is a truism that only the one who knows a great deal about a subject can write about it in a simple and convincing manner; and it is a wise precaution in these day , when truth is too often relegated to the back of the stage, while dramatic effect prances and pirouettes in front of the footlights, to be suspicious of "cleverness." Readers of "House Heating," however, have no need to be suspicious of this book. It is certainly the best treatise on the relative merits of coal, coke, gas, and electricity as alternative means of providing for domestic heating, cooking, and hot water requirements which we have yet encountered. The author, Dr. Margaret Fishenden, who is at present engaged upon investigations into problems of domestic heating for the Department of Scientific and Industrial Research, is well known to many readers of the "JOURNAL," on account of the valuable work which she has already accomplished; and the gas industry will be indebted to her for publishing a well-balanced book containing information on which full reliance can be placed.

The first chapter deals generally with fuels, and mention is made of the vast amount of raw coal which is still burned in our domestic grates. After reading this chapter one is impressed with the need for paying greater attention to the production of a high-temperature coke to replace much of this coal. Dr. Fishenden says that, as a domestic fuel, gas coke in this country has met with only a restricted measure of acceptance. This is due partly to its low volatile content, and partly to the amount of water which it frequently contains. Also, the "'sulphurous' smell often associated with coke fires burning below flues where the draught leaves something to be desired is another cause which has militated against its more general employment for household purposes, and which has led to the erroneous idea that coke contains more sulphur than coal."

Recent investigation into the problem of combustibility of coke—and we would refer particularly to the work of Sutcliffe and Evans—has proved that the structure of a coke has a large bearing on its combustibility, and is, indeed, the greatest influence. In view of this there seems to be a wide and almost unexplored field for the use of high-temperature coke for domestic purposes; and in thinking of this we are reminded of the stress laid by Sydney North and J. B. Garbe, in their recently published book, "Low Temperature Distillation," on the need for keeping in the forefront of low-temperature carbonization the object of producing the largest quantity of oil, and regarding the residual fuel as a secondary consideration. No doubt the Coke Competition—full details of which have appeared in the "JOURNAL"—will add to our knowledge of gas coke, and demonstrate the modifications whereby the gas industry may produce a coke suitable in all respects for domestic requirements.

Speaking of electricity as a heating agent, the author states that the low efficiency of its generation militates against its general adoption for this purpose. In the United Kingdom, an overwhelming proportion of the total electricity supply is yielded from the burning of coal; and in spite of the Final Report (1921) of the Water Power Resources Committee, Dr. Fishenden remarks that it is "very unlikely that the near future will see any considerable proportion of this potential power (water) harnessed, and for heat production electricity will probably remain relatively costly."

The development of the modern sitting-room grate and of the kitchen range, the use of gas and electricity for heating and cooking, and the development of central heating—these subjects are dealt with thoroughly. It would be an easy matter to write at length on the many points raised by reading "House Heating," for it is a book which encourages thought. Sufficient has been said, however, to indicate the value of the work; and Dr. Fishenden and Messrs. H. F. & G. Witherby are to be congratulated on the writing and production of a volume which has created a new standard in the literature of a subject of first-rate importance alike to the nation and the individual.

SCOTTISH JUNIOR GAS ASSOCIATION.

(WESTERN DISTRICT.)

MEMBERS OF COUNCIL, 1924-25.

Back Row (Left to Right): J. M'Intyre (Glasgow); W. Hogg (Glasgow); A. Shand (Falkirk); J. Hall (Provan); J. Brown (Glasgow); J. Teape (Glasgow).
Front Row: J. Murray, Hon. Secretary (Glasgow); Robert Gray, Vice-President (Hamilton); J. M'Isaac, President (Glasgow); A. Walker (Kilbarchan); and A. T. Sinclair (Greenock).

NATIONAL GAS COUNCIL.

SCOTTISH DISTRICT.

The Annual Meeting was held in the North British Station Hotel, Glasgow, on May 5—Councillor James Stewart, Convener of the Edinburgh Gas Department, in the Chair.

Annual Report.

Gas Regulation Act, 1920.—At the annual meeting in May, 1923, the proposal that municipalities in Scotland owning gas-works be advised to take early steps to adopt the Act, and apply the therm system of charge as from the commencement of the next financial year—namely, May 15, 1924, was unanimously agreed to. At this date 37 undertakings—municipal 33, statutory companies 4—have adopted the Act. The undertakings, with their declared values, are as follows:

Undertaking.	Present Declared Calorific Value.	Undertaking.	Present Declared Calorific Value.
	B.Th.U.		B.Th.U.
Municipal:		Municipal:	
Aberdeen	—	Holytown	400
Airdrie	425	Inverness	500
Alloa	440	Johnstone	420
Arbroath	450	Kirkintilloch	450
Bellshill	400	Lanark	470
Bridge of Allan	500	Larkhall	400
Cambuslang	400	Motherwell	400
Denny	550	Paisley	500
Dumbarton	425	Peebles	520
Dumfries	500	Perth	450
Dundee	450	Renfrew	450
Dunfermline	430	Troon	450
Dunoon	450	Uddingston	400
Edinburgh	500	Wishaw	400
Falkirk	430	Company:	
Glasgow	470	Busby	500
Grangemouth	500	Coatbridge	475
Greenock	410	Musselburgh	450
Hamilton	440	Stirling	475

It is learned that the experience of undertakings working under the Act has been satisfactory, and that there is not the slightest desire to revert to the old order of practice. The therm method has been favourably accepted by the public.

A deputation representing municipalities and other local authorities in England recently approached the Board of Trade suggesting that the adoption of the Act should be left to the voluntary action of the municipalities and authorities concerned. Mr. Ashley, Principal Assistant Secretary, Industries and Manufactures, Board of Trade, stated that "after two years from the passing of the Act the Board of Trade were empowered (under section 1 (5)) to make compulsory Orders; it obviously being the intention of Parliament that the new basis should ultimately be adopted throughout the whole of the gas industry. To the local authorities who had not yet applied for an Order the Board of Trade had given 2½ years' grace; but the time had come when it was necessary for the Board to decide what they were going to do to carry out what was clearly the intention of Parliament." The impression with which the deputation came away was that the Board of Trade would, sooner or later, compel every gas undertaking to come under the Act at an opportune moment for the undertaking.

The municipalities in Scotland who have not yet made application for an Order are as follows: Alva, Ardrossan, Bervie, Buckhaven and Leven, Burntisland, Campbeltown, Carnoustie, Darvel, Doune, Dunbar, Elgin, Forfar, Fraserburgh, Gourock, Helensburgh, Kilmarnock, Kilsyth, Kirkcaldy, Kirkcudbright, Kirkwall, Largs, Lockerbie, Millport, Monifieth, Newmilns, Newport, North Berwick, Peterhead, Port Glasgow, Sanquhar, Tain, and Tayport.

As regards the position of municipalities in Scotland, the Board of Trade desired to meet representatives. Accordingly a small deputation—Mr. James Campbell, of Dunfermline, President of the North British Association of Gas Managers, and Mr. J. W. Napier, of Alloa, along with Mr. Fottrell, of the National Gas Council—were received by Mr. Ashley and Mr. Honey on April 6. The discussion centred round the position of the very small undertakings. It was pointed out that in addition to the expense of providing the necessary apparatus with accommodation, and fees for gas examiners, there were incidental and practical difficulties in the cases of gas-works having a small annual output, and where there was no real staff. Also it did not appear that the small number of consumers concerned would be detrimentally affected, or that the coal carbonized—taking all the small undertakings together—was of substantial quantity, or that the small gas-works were in a financial position to introduce modern carbonizing plant with economy of coal. Mr. Ashley and Mr. Honey were satisfied with the evidence placed before them, and readily agreed that the position of the small gas-works required special consideration as regards the adoption of the Act. Mr. Ashley indicated to the deputation that the Board might agree that no steps be taken in compelling the adoption of the Act in the case of gas-works having an output of 25 millions and under but that consideration would require to be given to the subject.

Scheme for Sale of Tar and Ammoniacal Liquor to Distillers.—The scheme continues in successful operation. The monthly awards of values by the Arbiter are as follows:

		Tar. Per 100 Gallons	Liquor (4° Tw.). Per 100 Gallons.
		s. d.	s. d.
1924.	May	28 11½	3 0·625
	June	26 10½	2 9·375
	July	25 6½	2 9·375
	August	23 7½	2 9·375
	September	20 6½	2 7·75
	October	19 4½	2 7·75
	November	19 4½	2 7·75
	December	19 4½	2 7·75
1925.	January	19 11½	2 7·75
	February	21 3½	2 7·75
	March	21 11½	2 7·75

NOTE.—The above rates are at distillers' works, but railway dues from gas-works to distillers' works are paid by the gas undertaking.

Parish Council Assessment.—As the result of the statement of information sent to members, a number of gas undertakings have succeeded in obtaining an increased percentage deduction granted under section 37 of the Poor Law Act, 1845.

Government Legislation and Subsidies for the Development of Electricity.—Full information upon this subject has been sent to members, and the hope is expressed that practical attention will be given to the matter by Committees and Boards of Directors. The subject involves important questions of policy. The suggested subsidies in favour of electricity are calculated to injure materially the interests of the gas industry in general. Those responsible for the administration of individual undertakings are expected to take action in the manner suggested by the Central Executive Board in the special booklet and circular letter issued.

Mr. S. S. Ogilvie (National Gas Council) explained the action proposed to be taken in connection with the suggested Government Legislation for the development of electricity. Mr. W. E. Whyte (Lanarkshire) referred to the same question, and suggested that it would be most desirable if local authorities in Scotland were to have a conference on the subject, with a view to taking steps to safeguard the interests of gas undertakings. Mr. Whyte's suggestion was unanimously agreed to, and an early meeting will be arranged for.

British Empire Exhibition, 1925—Gas Exhibit.—The sum contributed by gas undertakings in Scotland for the 1924 exhibit was about £5000. The Committee heartily commend the attention of Committees and Directors to support the scheme, which includes, besides the actual exhibit, a wide publicity campaign in the Press. Undertakings are asked to subscribe one-half of the amount they contributed to the 1924 exhibit, or 3s. per million c.ft. of gas made.

Membership.—The number of Scottish undertakings in the membership of the National Gas Council is as follows: Companies 66 (last year 66), corporation 44 (last year 44).

The following appointments were made for 1925-26:

MANAGEMENT COMMITTEE.

Chairman.—Councillor James Stewart (Edinburgh).
Vice-Chairman.—Bailie Slorach (Hamilton).
Secretary.—Mr. J. W. Napier (Alloa).

The following twelve members: Messrs. George Braidwood (Coatbridge), James Campbell (Dunfermline), James Dickson (Dundee), T. W. Harper (Ayr), L. Hislop (Cowdenbeath), Bailie Hunter (Perth), John Lang (Alexandria), George Keillor (Greenock), Samuel Milne (Aberdeen), J. W. M'Lusky (Glasgow), John M. Smith (Stirling), and W. E. Whyte (Lanarkshire).

Representatives on the Central Executive Board, with year of retiral.—Bailie Slorach (1926), Mr. J. W. Napier (1927), Mr. L. Hislop (1928), and Councillor James Stewart (1929).

Memorial to the late Lord Moulton.—A scheme has been adopted by the friends and admirers of the late Lord Moulton for the erection of a permanent memorial to his great achievements in the legal and scientific spheres, and, in particular, his invaluable services to his country in the war. The scheme comprises the conversion of the main schoolroom of the Kingswood School, Bath, into a Lord Moulton Memorial Hall.

The "Electrician" Annual Tables of Electricity Undertakings.—Messrs. Benn Brothers, Ltd., 8, Bouverie Street, E.C. 4, have published the Annual Tables of Electricity Undertakings for 1925. The Tables have been thoroughly revised, and further useful details have been added. Particulars of over a hundred additional undertakings in Great Britain, Europe, and the Colonies and countries abroad appear, while complete lists of the smaller concerns in Yugo-Slavia and Roumania are given for the first time. Altogether over 2000 undertakings are dealt with, and the new edition has been expanded by twenty pages. The price of the work is 10s. net, postage 6d. extra.

ROAD TAR EXHIBIT

OF THE NATIONAL GAS COUNCIL AT WEMBLEY.

[*Photo. Campbell-Gray.*

(*For description, see p.* 460.)

MIDLAND ASSOCIATION AT OXFORD.

In concluding his Presidential Address to the Midland Association of Gas Engineers and Managers in March, Mr. W. E. Caton, A.M.I.Mech.E., the General Manager and Engineer of the Oxford Gas Light and Coke Company, extended an invitation, on behalf of his Directors, to the members to visit their beautiful city for the summer meeting. Thus Thursday, May 7 (the date fixed), was a day which will long be remembered with pleasure by a large number of members and friends.

AT THE GAS-WORKS.

The morning was spent at the gas-works, where the visitors were welcomed by the Chairman of the Company (Alderman F. W. Ansell, J.P.), the Vice-Chairman (Mr. Walter Turrill), Alderman Dr. G. Claridge Druce, and Mr. R. C. Downing (Directors), and Mr. Caton, who, with Mr. H. A. Coombs (Assistant Engineer and Works Superintendent) and Mr. S. Colebourne (Chemist) showed them round. In his address, Mr. Caton had prepared the members for seeing a good deal of work in progress, but the extent of it proved a surprise to many of them. The reason for the entirely new unit, from retort house to meter house, which is being put down, is to be found in the fact that, when Mr. Caton was appointed General Manager and Engineer in 1916, the consumption amounted to only 100 million c.ft. By 1918 it had increased to 433 millions; and since then the growth has been still more rapid—the figure for 1924 reaching 723 million c.ft. Naturally, this rapid increase in output, due mainly to cooking and heating, severely tried the productive capacity of the existing works; and so a completely new works was decided on, to be erected on a site adjacent to the old site, to be used as an additional manufacturing station—not in substitution for the present one. It may be mentioned here that prior to the war the price of gas was 2s. 6d. per 1000 c.ft. to ordinary consumers within the city, and 3s. outside; while since July 1, 1923, the charge has been 8⅝d. per therm in the city, and 9½d. outside—or 3s. 2·64d. and 3s. 8·16d. per 1000 c.ft. respectively.

The works are located on the south-west side of the city, and occupy an area of 20 acres. They are situated on both banks of the River Thames, which divides the new manufacturing station in course of erection from the present works. The Company have two sidings from the Great Western Railway into the works. The one serving the present works passes over the River Thames, and is carried by a girder bridge, the property of the Gas Company, and thence by a viaduct into the retort house; that serving the new works goes direct into the works.

Existing Works.

Coal trucks are shunted by the Company's own locomotive along elevated sidings, on both sides of the retort house, where they are unloaded by hand into hoppers, from which the coal is fed into the breakers and elevators. The elevator on the discharging side delivers on to a band conveyor, which takes the coal across the retort bench into an overhead hopper on the charging side.

The carbonizing plant consists of two benches of ten and thirteen horizontal retort settings with Klönne regenerators; each bed containing eight retorts 21 in. by 15 in. by 20 ft. long. The safe working capacity of this plant is 2½ million c.ft. per day, with best selected coal or washed nuts. The charging and discharging are carried out by separate machines of the De Brouwer type, operated by electricity. For three years Mr. Caton has been getting over 70 therms per ton of coal.

The coke, on being discharged from the retorts, falls through openings in the stage floor into bogies beneath, where it is quenched. The bogies are drawn by means of a wire-rope haulage system up an inclined track outside the retort house and along an elevated gantry, where the coke is tipped on the main storage heap or into a hopper for feeding the coke elevator. The haulage system is driven by a 25 h.p. motor, which is operated by a series of push-button controls fitted at intervals alongside the track. The hopper fed by the coke-haulage system discharges into an elevator, which can be used either for loading direct into railway wagons or for discharging through a breaker and rotary screen, where the coke is graded and falls into bins. The whole plant is driven by one 11 h.p. electric motor.

The power house contains two 15 kw. and one 25 kw. generators, all manufactured by the Lancashire Dynamo and Motor Company, Ltd., direct driven by Crossley gas engines of 25 and 40 h.p. respectively. D.C. current (220 volts) is used for driving the stoking machinery, coke haulage gear and elevator, and screening plant.

Other plant includes a horizontal atmospheric condenser and a Clapham water-tube condenser. There are two tower scrubbers, 60 ft. high by 10 ft. diameter—one fitted with a Livesey tar extractor at the bottom; and a Walker purifying machine, which is similarly fitted with a Livesey tar extractor.

The dry purification is practically all done with a set of four purifiers, 40 ft. by 30 ft. by 5 ft. deep, with water lutes, erected by Messrs. C. & W. Walker. There is a second set of three purifiers, 25 ft. by 25 ft. by 5 ft., with water lutes, which can be worked in parallel with the main set; but, owing to difficulty in handling, these have not been worked for some years. There are also two luteless catch boxes, 40 ft. by 40 ft. by 6 ft. deep, by Messrs. C. & W. Walker.

The Parkinson station meter is of a capacity of 150,000 c.ft. per hour. There are three gasholders (besides the water gas relief holder); the capacities being ½ million, 1 million, and 2 million c.ft. respectively. The last-mentioned was recently constructed by Messrs. C. & W. Walker, and brought into commission in September last. Three 18-in. Parkinson station governors supply separate districts, but the districts are ultimately connected up.

There is one carburetted and one blue water gas plant, of Messrs. Davison & Partner's manufacture; the nominal capacities being 600,000 and 500,000 c.ft. per day respectively. There are a water-tube condenser and two scrubbers common to both sets. The unpurified water gas is sent into a relief holder having a capacity of 300,000 c.ft.; and from the holder it is drawn as required into the coal gas mains at the inlet to the exhausters after first passing through a rotary meter.

The ashes from the retort house and the water gas plant are taken to a Type B. 1 "Columbus" separator, which produces coke 43 p.ct., clinker 25 p.ct., and fine ashes 32 p.ct.

Works Under Construction.

The site of the new works is subject to flood, and consequently the ground level is to be raised about 4 ft. The new retort house will be a steel-framed building filled in with concrete block work. The first bench of retorts will consist of eight beds of Klönne settings of 8 section retorts 24 in. by 17 in. by 22 ft. long. The lay-out of the works is arranged so that the house can be extended for two more similar benches.

The coal trucks will be emptied by means of a rotary tippler into a hopper outside the retort house, where the coal will be broken and elevated into the retort house. There it will be discharged on to a push-plate conveyor running over continuous coal hoppers, a 30-ton hopper being erected opposite each bed. The stoking machinery will consist of a De Brouwer charging machine and separate discharging machine on one side, with an additional discharging machine on the opposite side of the house. The latter machine is for feeding the producers, which are placed on the charging side. The object of this is to keep the furnaces on the opposite side to the coke handling plant, which will be on the same system as in the old works. The coke will be discharged through openings in the stage floor into trucks, where it will be quenched, thence running out of the retort house to an elevated gantry—the trucks being operated by an electric rope haulage system.

Water-tube condensers only will be employed. Two sets of exhausters will be installed, each set consisting of a horizontal steam engine coupled to an 80,000 c.ft. per hour exhauster, with provision for fixing a 100,000 c.ft. per hour exhauster on to each engine. Two Lancashire boilers, 30 ft. by 8 ft. 6 in. diameter, will be fixed at first, the boiler house being large enough to accommodate four boilers eventually. Two 100 kw. steam-driven sets will be installed, each consisting of a vertical compound steam engine direct coupled to a dynamo. One Livesey washer and one rotary scrubber will be provided to begin with.

The first section of the purifying plant will consist of five purifiers 35 ft. by 30 ft. by 6 ft. deep. These will be arranged on the ground level in a single row, with a revivifying shed running along either side. Owing to the proximity of the river and the city water-works, the main tar and liquor tanks are to be constructed of cast iron, and erected above the revivifying floors at either side of the purifiers. The size of each tank will be 166 ft. 6 in. long by 26 ft. 6 in. wide by 6 ft. 6 in. deep.

Special interest was taken in the concrete block making installation; the product being utilized for the new buildings. The composition of these blocks is cement 1, sand 2, and ashes 2; four men being engaged in preparing the material and making the blocks, a large proportion of which are moulded in a Winget machine. The total number made daily is about 250.

The makers of the plant erected and ordered up to the present time are:

Concrete blocks	Oxford Gas Light and Coke Company.
Foundations, retort settings, and block-work	Messrs. Thos. Vale & Sons.
Railway weighbridge	Messrs. H. Pooley & Sons.
Tippler, elevator, and conveyor	West's Gas Improvement Company.
Steel-framed retort house, buckstays, steel hoppers, stage floor, and stoking machinery	Messrs. W. J. Jenkins & Co.
Mouthpieces, ascension pipes, hydraulic mains, foul mains, &c.	Messrs. Westwood & Wrights.
Steel-framed pump house, &c.	Messrs. Westwood & Wrights.
Condenser	Messrs. C. & W. Walker.
Livesey washer	Messrs. C. & W. Walker.
Rotary scrubber	Whessoe Foundry and Engineering Company.
Exhausters	Bryan Donkin Company.
Generating sets	Messrs. Belliss & Morcom and the Lancashire Dynamo & Motor Company.
Purifiers and connections, purifying and revivifying houses, with overhead tar and liquor tanks	Messrs. C. & W. Walker.
Station meter and retort house governor	Messrs. W. Parkinson & Co.

There is a block of offices at the existing works, comprising e Engineer and General Manager's Office, Assistant Engineer d District Superintendent's Office, Works Office, and the ot Meter Department Offices.

GENERAL.

Excellent showrooms, opposite Christ Church College, were ened in February, 1921, and have proved a very great quisition to the Company. All the gas lamps in the district supply, numbering 1537, are of the inverted superheated uster type, of Messrs. William Sugg & Co.'s manufacture; id each lamp is controlled by a Gunning clockwork controller. hese controllers have been in operation since 1907. The de-ared calorific value of the gas is 460 B.Th.U., and that pplied averages 470 to 480 B.Th.U.

HOSPITALITY.

After the inspection, a party numbering about eighty sat wn to luncheon in the Assembly Room at the Town Hall, by vitation of the Chairman and Directors of the Oxford Gas ompany. Alderman Ansell was in the chair, and he was sup-rted by the Mayor (Mr. Amos J. George), the Deputy Mayor, e Sheriff, and members of the Town Council and the Univer-ty. There were also present Mr. J. Ferguson Bell (President the Institution of Gas Engineers), Mr. W. H. Johns (Presi-ent of the Wales and Monmouthshire District Institution of as Engineers and Managers), and Mr. H. C. Smith (Hon. ecretary of the Southern Association of Gas Engineers and lanagers). After the honouring of the Loyal Toast,

Mr. HUBERT POOLEY submitted "The City of Oxford." He said e found that Oxford was first mentioned in history when King dward the Elder recovered it from the Danes in 912; and right rough those long centuries since then the city had been one of the ief centres of interest and enlightenment. Organized study, they ere told, began in Oxford about three centuries later than the year e had just named. The oldest college endowment was that of niversity College, which dated from about 1249. One was reminded at such famous men as Bacon, Wycliffe, Wolsey, Tyndale, Raleigh, lake, Pitt, and a host of others, were all connected with Oxford—ot to forget Sir Thomas Bodley, whose name was borne by that onderful library—one of the city's proudest possessions. He felt retty sure that Oxford's most important industrial effort had been ie University Press, which, as the Clarendon Press, was founded bout 1672, and had flourished under the wing of the great University ver since. One was, perhaps, tempted to criticize the authorities f that age for allowing the art of printing to advance in Europe for century-and-a-quarter before founding the press which was now orld famous; but, if one had any such uncharitable thought, one as filled with admiration for the wisdom of all the generations of Oxford men, who had surrounded her students with the beauty of her ublic places. There was a remarkable calm and majesty about he city. "Time will only permit me," he went on, "to hint at the igh hope we all have in Oxford, that the rising and future genera-ions which pass through your hands may uphold the traditions you ave already earned in that knowledge and understanding, integrity, nd high honour for which the best Oxford-trained men have been enowned." So far as the Association were concerned, Oxford for nany years meant to them Mr. Eldridge. The city was well served by im in the days that were past; and in their President he was sure he Company had already found a worthy successor.

The MAYOR said nothing could have done more to make his task f replying easy than the genial terms in which the toast had been proposed. The citizens had always felt that they had every reason to e proud of the history of Oxford. They welcomed the Association in he heartiest manner possible, and hoped they would carry away nemories which they would long cherish.

Mr. J. FERGUSON BELL, proposing "The Oxford Gas Light and Coke Company," said they had that morning inspected the large ex-ensions now in progress at the gas-works, which demonstrated the perspicacity of the Directors and the ability of their capable Engineer. Any engineering construction in Oxford had to satisfy some very critical eyes. It was one of the most beautiful of English cities, and any building, therefore, would be expected to reach a high level in appearance. But there was no reason at all why modern engineering construction should be ugly. He ventured to assert that the additions to the Oxford Gas-Works fully complied with the requirements, and when completed would be a credit to the city as well as worthy of a progressive Company. The Oxford Gas Company were very old estab-lished, having obtained their first Act of Parliament as far back as 1818. Like the many famous colleges for which the beauteous city was renowned, the reputation of the Company was not diminished by age, but continued to advance. The new works indicated the rapid progress in the use of town gas in the city. This was exactly what one would expect in a place like Oxford. The citizens must desire that every precaution be taken to preserve the gems of architectural beauty which not only adorned the city, but were of priceless value as a national asset. The use of raw coal for domestic and trade pur-poses should be discontinued, as it meant a smoky atmosphere, pol-luted with soot and sulphurous products, which were not only in-jurious to health but destructive to buildings. It was no wonder, then, that the citizens, who were so justly proud of their colleges, were using gaseous fuel in increasing quantities; and they happily pos-sessed a progressive Company able and willing to provide this on most reasonable terms. The pre-war charge for gas in Oxford was 2s. 6d. per 1000 c.ft. within the city and 3s. without; and the price to-day was only 3s. 2½d. in the city, which, considering the geographi-cal position of Oxford in respect of coal supplies, was an abnormally low figure, and indicated that the undertaking must be ably managed. They all knew the purchasing power of a sovereign was not more than 12s. to-day; so on this basis the post-war charge for gas in Oxford should be 4s. 2d. per 1000 c.ft., whereas it was only 3s. 2½d. The Directors and their very able Engineer and General Manager, Mr. Caton, were entitled to be proud of this low price; and he congratu-lated them—as well as the citizens of Oxford—upon being able to obtain town gas upon such satisfactory terms. He desired to express the members' appreciation of everything that had been done for them that day. ["Hear, hear."]

The CHAIRMAN replied that when an industry was served by gentle-men possessing the qualifications of those he saw around him, neither Directors nor shareholders would have any cause to complain. There was no fear of the powers given to gas companies by Act of Parlia-ment being exercised otherwise than in the best interests of everybody.

Dr. CLARIDGE DRUCE proposed "The Midland Association of Gas Engineers and Managers," to whom, he said, a most cordial wel-come was extended by the Gas Company. The Directors regarded such gatherings as helpful to themselves and to everyone concerned. In making Mr. Caton their President, they had honoured the Com-pany he served, as well as him.

Mr. CATON, in rising to respond, tendered the warmest thanks of the Association to the Chairman and Directors of the Company for their kind hospitality, which he took as a personal compliment and honour to himself. They had all along displayed the greatest enthusiasm with regard to his Presidency of the Association.

Mr. JAMES PATERSON submitted "Kindred Associations," remark-ing that it was a matter of the greatest satisfaction to them all that this year both the President of the Institution of Gas Engineers and the President of their Association should be men from the Midlands. The President of the Wales and Monmouthshire Institution (Mr. Johns) was also at one time a member of the Midland Association.

Mr. W. H. JOHNS, in response, said Mr. Caton was one of his oldest friends in the gas industry, and he was proud to see him in the position he occupied that day. He congratulated the Board and their Engineer on the splendid lay-out of the new plant, and felt posi-tive that the very best results could be expected from it. Care and forethought were evident in all directions. ["Hear, hear."] Mr. Caton for many years faithfully served Mr. Ferguson Bell; and it was very gratifying to find Mr. Bell present to support him.

The DEPUTY-MAYOR proposed "The University of Oxford," which was responded to by the Rev. G. CRONSHAW (Bursar of Queen's College).

Luncheon was succeeded by a short business meeting in the Council Chamber, at which one or two formal announcements were made.

A delightful afternoon followed, visits being made to a num-ber of the principal Colleges, under the able guidance of Dr. Druce, Mr. James Eldridge, and Mr. Harry Paintin—thanks to whom were voiced by Mr. Bell. Tea with the President and Mrs. Caton (for which they were heartily thanked on the pro-position of the Vice-President, Mr. F. C. Briggs, seconded by Mr. P. N. Langford) ended a thoroughly enjoyable day.

INTERNATIONAL COMMISSION ON ILLUMINATION

(*Concluded from Vol. 169, p. 606.*)

The Plenary Meeting of the Sixth Session of the Commission was held on the morning of the last day of the meeting, at Geneva—Dr. HYDE, the President, occupying the Chair.

The GENERAL SECRETARY (Mr. J. W. T. Walsh) read various messages of goodwill which had been received from the Presi-dent of the Canton of Geneva, the Institution of Gas Engi-neers, the Belgian Association of Gas Engineers (who intend to apply for representation on the Commission), the Société Technique de l'Industrie du Gaz en France, Snr. Artigas, of Madrid, Sig. Bordoni (Italy), and M. Rouland, of Paris.

The whole morning was devoted to the consideration and adoption of various resolutions resulting from the work done at the technical meetings, to the election of officers, and to the submission of the triennial budget of expenditure.

The report of the National Illumination Committee of Great Britain will be published next week.

The following were elected as officers for the next meeting, which it was decided should be held in the United States of America, in 1927, preferably in the autumn:

President.—Dr. E. P. Hyde (re-elected).

Vice-Presidents.—Sig. Semenza (Italy), M. Rouland (France), and Col. Edgcumbe (Great Britain).

Hon. Secretary and Treasurer.—Mr. C. C. Paterson.

General Secretary.—Mr. J. W. T. Walsh.

After expressions of thanks to Sir Joseph Petaval, Director of the National Physical Laboratory, for his valued co-operation, the Treasurer's recommendations were adopted.

A hearty vote of thanks was passed to the Swiss National Committee for their generous and helpful entertainment of the Commission during the meeting at Geneva, and for the ex-ceedingly efficient arrangements which they had made for the accommodation and business of the Commission. Appreciative reference was also made to the assistance received from the State Council of the Canton of Geneva, and to the League of Nations for the provision of two excellent French and English interpreters.

SOCIAL AMENITIES.

It only remains to refer to the hospitable arrangements made by the Genevese town authorities, and other hosts, for the social entertainment of the delegates who attended the meeting.

On the Tuesday evening a dinner was given by the Admini-strative Council of Geneva, at a restaurant on the banks of

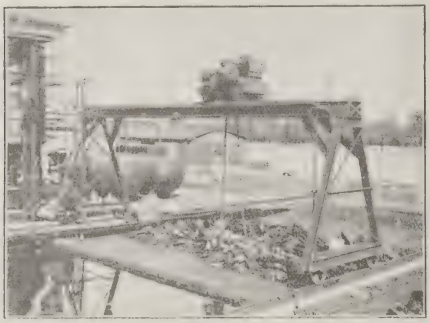
the lake—Belle Rive. The Swiss National Committee gave a dinner at the Hôtel des Bergues the next evening. M. A. Filliol, Director of the Electrical Service of Geneva, was President of this Committee, and M. F. Largiader acted as Secretary. Both gentlemen were indefatigable in attending to the comfort of all.

Thursday afternoon was occupied by a visit to the Labour Bureau of the League of Nations and to the Office of the League of Nations itself—Hôtel des Nations. At both places the members were invited to ask questions on the constitution, operation, and utility of these international organizations. Much interesting and useful information was communicated; and the thanks of the Commission for the courtesy extended were suitably expressed by Dr. Hyde, the President. On the evening of Thursday another enjoyable reunion took place, consisting of a dinner given by the Commission to their Genevese hosts and to other guests. It was held at the Parc des Eaux-Vines, delightfully situated near the lake.

PITCH GETTING AND LOADING.

The Woodall-Duckham Vertical Retort and Oven Construction Company have recently acquired a licence to sell a novel installation for getting and loading pitch from bays, which considerably reduces the cost of operation, enables the work to be carried out in much quicker time, and avoids the necessity for having men working in the pitch bay for long periods, and running the risk of becoming infected with those diseases generally associated with this operation.

Briefly, the process consists of laying a chain in serpentine fashion in an empty pitch bay, and connecting one end of the chain to a crab operated by a motor carried on a trolley travelling on an overhead support running the width of the pitch bay, as shown in the accompanying illustration. When required, the



support for the trolley can be moved along the bay by means of hand-operated gears. After the chain has been laid, pitch is run into the bay to a depth of approximately 20 in., and is then allowed to set, after which another chain is laid on the cold pitch, and a similar depth of pitch is again run in, and allowed to set. The numbers of layers of pitch which can be laid in this fashion is governed by the depth of the bay. When it is desired to "get" the pitch, the crab on the trolley is put into operation, and starts hauling on the uppermost chain. The crab and motor travel to the point of attack automatically, gradually drawing-up the chain from the bay, and in so doing breaking-up the pitch into pieces, the maximum size of which is roughly 20 in. square.

The method employed for pulling the chain is such that the whole operation can be carried out, at the rate of 4 ft. of chain per minute, by a motor of approximately 5 B.H.P.

The pitch, which should be run into the bay at a temperature of not more than 250° C., has no effect on the links of the chain; and practically no dust is produced during the operation of breaking.

After the material has been broken-up, it is conveyed into trucks by means of a small movable loading conveyor. By this system it is possible to break-up pitch at 1·5d. per ton, and load into railway wagons alongside the bay at 3d. per ton.

One of these installations has been in operation at Kiel for two years, and it can be safely stated that the maintenance cost is extremely small.

Gas Mantles Committee.—The Committee appointed by the President of the Board of Trade to inquire into, and report upon, an application made by the Incandescent Mantle Manufacturers' Association for the imposition of a duty upon gas mantles, propose to hold public sittings for the taking of evidence at 10.15 a.m. on Friday, May 22, and Monday, May 25, at the Board of Trade, Great George Street, London, S.W.

WALES AND MONMOUTHSHIRE JUNIOR GAS ASSOCIATION.

The Third Annual Meeting was held at Newport on Saturday, May 2.

Mr. B. J. Bell (President) said that they were honoured by the presence of Mr. J. H. Canning, of Newport.

Mr. J. H. Canning, on behalf of the Chairman and Directors of the Newport (Mon.) Gas Company, welcomed the Association. He congratulated the Association upon the well-deserved success achieved, which was largely due to the enthusiastic way in which the members had taken up the work. Mr. Canning referred to the intensified electrical competition with which the gas industry now had to cope. At Newport they were displacing many electric cookers and heating appliances. He counselled them all, whatever their position in the industry, to use their best endeavours to keep in close touch with the public, and strive to give consumers the facts. If they were to do this, however, they must be able to speak of the merits of gas. He encouraged the members to cultivate the art of public speaking.

Mr. Bell moved a vote of thanks to the Chairman and Directors of the Newport Gas Company for their hospitality and kindness in affording facilities for their meeting, and also to Mr. J. H. Canning for his presence and encouragement.

Mr. R. G. Shute (Cardiff) seconded the motion, which was carried with acclamation.

Statement of Accounts.

In the absence of Mr. R. J. Auckland, the Hon. Treasurer, the statement of accounts for the past year was presented by Mr. Osborne (Cardiff). The total income amounted to £38 18s. 5d., and the expenditure to £30 9s. 11d., leaving a balance in hand of £8 8s. 6d.

The President said that the position disclosed was eminently satisfactory; and he took the opportunity of informing the meeting of the generosity of Mr. T. Noall (Cardiff), one of their members, who had contributed £2 2s. to their funds.

Following discussion, the statement of accounts was passed on the proposition of Mr. Shute, seconded by Mr. C. S. Bateman (Cardiff).

The report of the Council was read by the Secretary, Mr. W. E. Crowley.

Mr. J. Hislop moved, and Mr. T. A. Canning seconded, that the report be accepted, and an expression of the thanks of the Association to the Council and Secretary be recorded.

The President supported, paying a warm tribute to the work of the Secretary.

The motion was carried with acclamation.

The Secretary announced that he had received a letter from Mr. R. J. Auckland, resigning the office of Hon. Treasurer to the Association.

It was resolved, on the proposition of Mr. Hislop, seconded by Mr. C. S. Thane (Newport), that Mr. Auckland's resignation be accepted, and that he be thanked for his services as Hon. Treasurer, and for the invaluable support he had at all times given to the Association.

On the proposition of Mr. R. J. Williams (Abertillery), seconded by Mr. H. G. Brown (Cardiff), it was unanimously decided to ask Mr. R. J. Auckland to accept election as the first Honorary Member of the Association.

The President declared the result of the election of officers and Council for the following session:

President.—Mr. J. Wood, Pentre.
Senior Vice-President.—Mr. D. M. John, Aberdare.
Junior Vice-President.—Mr. C. S. Bateman, Cardiff.
Hon. Treasurer.—Mr. A. H. Shepperd, Swansea.
Hon. Secretary.—Mr. W. E. Crowley, Newport.
Auditors.—Mr. R. E. Foster, Cardiff, and Mr. T. Noall, Cardiff.
Members of Council.—Messrs. T. Hunt, Porth; C. H. Collins, Swansea; G. H. G. Hughes, Chepstow; and V. T. Blake, Cardiff.

Mr. T. A. Canning (Newport) proposed that the rules of the Association be amended to permit of an associate membership class being formed.

Mr. G. H. G. Hughes (Chepstow) seconded the motion, which was supported by Mr. Collins (Swansea) and Mr. T. Smith (Cardiff).

The proposition was carried unanimously.

Mr. T. A. Canning moved that the Association extend a sincere vote of condolence to the relatives of the late Mr. H. E. Jones. The work of the late Mr. Jones was too well known to need reiteration, but it might be pointed out that at one time he had been engaged at Pontypridd.

The vote was seconded by Mr. Bateman, and accorded by the members standing in silent respect.

Votes of thanks to the President and to the Scrutineers and Auditors concluded the meeting.

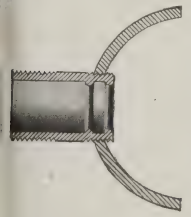
THE "DU-EX" NIPPLE.

It is now a number of years since steel tubes first began to set fresh problems in mainlaying. One of these problems concerned the connecting of services to a main whose shell was of much less thickness than had formerly been negotiated with screw threads, but was, at the same time, of far greater strength. It was necessary to provide some device that would make use of the strength and also provide soundness.

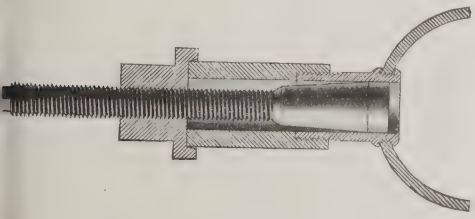
The inventor of the expansion nipple perceived that, by expanding or riveting a nipple against the interior of the wall of the main, strength could be obtained to pull against, and this strength could be utilized for the pressing down of an exterior saddle joint with gutta percha ring—the latter to be depended upon for soundness.

A great deal of experiment was made to determine the exact shape of this saddle joint, and tests were carried out under drastic conditions. The sizes chosen for the tests as an extreme proposition were a 1 in. nipple screwed into a 3 in. main, a ratio of 1 to 3, though 1 in 4 is recommended in general practice. The expansion nipple and saddle joint, which have held the field for so many years, passed this initial test; and, provided the nipple has been screwed right home and expanded truly within the main, the joint has been so satisfactory as to add not a little to the utility of steel mains.

True progress, especially in these days when economy is vital to industry, should move in the direction of simplicity. Now the "Du-Ex" nipple has been devised to supersede the expansion nipple. By an ingenious adaptation of the original idea, the expansion nipple is to be rendered independent of its adjunct, the saddle joint. A second expansion has been added, without increase of cost for the nipple, and making no difference in the method of working, or the tools employed; but it does away with the saddle and packing ring. The "Du-Ex" nipple gives soundness as well as strength; it has passed the drastic test of a 1 in. nipple in a 3 in. main. A glance at the illustrations will show how the nipple is formed—with two internal ledges, the one for expansion inside the main, and the other outside. Thus the expansion is now effected evenly against the wall of the main, and the threads of nipple and main, though few in number, are so evenly pressed together that no fluid can escape. Here again, as with the single expansion nipple, it is, of course, essential that the nipple shall be screwed right home. The space between the two ledges by which the nipple is expanded is commensurate with the thickness of the wall of the main, or, rather, with the thickness *plus* the curve, for small mains with less gauge and more curve take the same nipple as the larger mains with thicker gauge and less curve. Here is simplicity exemplified, for, without the saddle joint, it is no longer necessary to specify the size of main, and the "Du-Ex" nipple can be stocked merely in accordance with the diameter of services.



Before Expansion.



Expanded.

In case there should be any reader not familiar with the working of the expansion-nipple, we reproduce the routine for the "Du-Ex," as laid down by the makers:

The main is drilled and tapped as usual (with special combination drill-taps provided) and the "Du-Ex" nipple is screwed-in, with the mandrel sleeve and nut attached. Then, by means of a ratchet spanner, the nut is turned, and the mandrel thereby drawn out until it has passed both ledges. It then comes away free, leaving the nipple firmly gripped in the main—so firmly indeed that it cannot be unscrewed by any ordinary means, or wrenched out by any conceivable accident.

In service laying it remains to give the exterior of the "Du-Ex" connection a similar coating and wrapping to that which is usually applied to the main joints. Engineers who desire to make assurance doubly sure, and do not mind the extra expense and the inconvenience of keeping stock, can yet add the saddle and packing ring to the "Du-Ex" nipple. It is a remarkable convenience that the introduction of this improvement makes no disturbance to existing tools or methods.

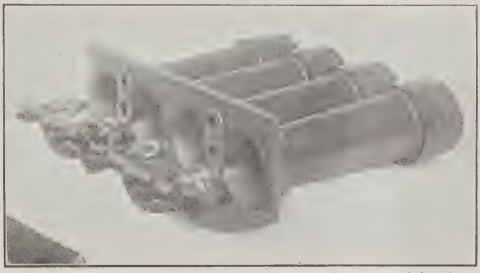
For spun cast-iron pipes the thickness of which is greater than that of steel, but less than cast-iron, the "Du-Ex" nipple is made with a greater space between the two expansion ledges.

The patent for the "Du-Ex" nipple is in the names of T. W. Meakin, B. R. Parkinson, and the firm of J. Stone & Co., Ltd., of Deptford (the latter are also the sole manufacturers).

WILTON'S PATENT ECONOMY JETS FOR FORCED-DRAUGHT FURNACES.

Users of steam-jet operated forced-draught furnaces burning low-grade fuels will be further interested in the latest improvements by the Chemical Engineering & Wilton's Patent Furnace Company, Ltd., in the furnaces manufactured and sold by them. With this improvement, besides being able to burn the cheapest and lowest-grade fuels without affecting the efficiency and evaporative power of the boiler, they will be able to effect further saving of fuel by fitting the new design of blowing apparatus to their existing grates.

After numerous and careful experiments carried-out along strictly scientific lines and under actual working conditions, it was found that the amount of steam used to create the blast on various kinds of steam-jet operated grates was excessive, especially when burning the lower grades of fuel.

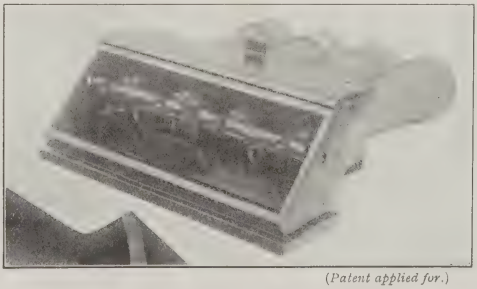


(*Patent applied for.*)

Blower with Bridge and New Type Jets
(Silencing box removed).

The blowing apparatus has been redesigned, and can be fitted to almost any furnace of this type, while the new jets, which embody a slight but important modification of the venturi principle, have been found to reduce to the extent of 55 p.ct. the amount of steam required to produce the maximum blast. While the efficiency has been increased by this amount, the new blowers provide exactly the same amount of air throughout the furnace grate as hitherto, at equal static pressure over the whole grate area.

The saving which can be effected is remarkable, and the engineer using this type of grate who requires to reduce his fuel costs to the minimum should not hesitate to adopt these new principles in his existing Wilton furnaces. It was found



(*Patent applied for.*)

Blower Jets and Silencing Box
(Cover removed).

that on a Lancashire boiler evaporating 3246 lbs. of water per hour, burning coke breeze of a calorific value of 10,000 B.Th.U. per lb., a saving of 6 cwt. of fuel per day was possible, representing, when working 7 days a week and 24 hours each day, a saving of 42 cwt. per week. The furnaces are covered by patents and protected designs. It may be added that the latest pamphlet regarding this is of great interest, and the makers will be pleased to furnish copies to all who care to apply.

SAMPLING OF COAL.

[Abstract of a Paper by F. H. Walker, B.Sc., A.I.C., of the South Metropolitan Gas Company, before the Newcastle Section of the Society of Chemical Industry.]

Accuracy in sampling depends mainly on :

1. The collection of a sample evenly from all parts of the bulk to be sampled.
2. The ratio of the weight of the sample to the weight of the bulk to be sampled.
3. The ratio of the largest pieces of impurity in the sample to the weight of the sample collected.
4. The fineness to which the sample is crushed for each stage in its reduction.
5. Proper mixing before each reduction.

It is very necessary, when collecting samples from trucks, to take portions from the bottom and middle parts of the load, and not only from the top. In a certain case a truck was found to contain coal at the bottom with an ash content of 8 p.ct. more than that at the top.

Sampling Cargoes of Gas Coal from the Northumberland and Durham Coalfields.

The sampling and inspection staff consists of six samplers and four youths, under the supervision of an inspector. Covered accommodation is available on the ships, with an iron floor on which samples may be crushed without fear of contamination. This cabin is not used for any other purpose. The samplers aim at collecting four or more "gross samples," each approximately 1000 lbs. in weight, from each cargo.

A gross sample is collected by plunging a special sampling ladle into the stream of coal as it pours from the shoot into the ship's hold. Quantities of 10 to 20 lbs. are collected by the sampler in this manner at regular intervals during the whole period of loading each of the four hatches, or as long as time permits. The collected coal is carried to the sampling cabin in ordinary buckets.

When the collection is completed, the gross sample is divided into two parts—over ½ in., and less than ½ in. size by screening, and the weight of each part ascertained. The pieces of dirt are then picked out by hand from the larger size, weighed, and well pulverized by means of an iron punner. This dirt represents what ought to be removed on the picking belts at the collieries under ideal conditions. The large coal is crushed to 1 in. size or less.

The crushed dirt is then mixed with the "small" coal by repeated coning, and this mixture in turn is mixed with the crushed "large" coal. This method of crushing and mixing is adopted to render more certain the even distribution of the dirt in the sample. Great importance is attached to the proper mixing of the gross sample before the first reduction. The difficulty of carrying out this operation by hand labour renders undesirable the collection of gross samples of more than 1000 to 1200 lbs. The first reduction of the gross sample to 500 lbs. is made by the long pile and alternate shovel methods. This system of reduction is more convenient than the cone method in a limited floor space; it possesses no other advantage.

The subsequent crushing and reduction are carried out in a similar manner to that described in Bulletin No. 116 of the U.S. Bureau of Mines, with the exception that all mixing is carried out on the iron floor, and not on a blanket. An iron sample cutter is used to facilitate the divisions of cones into four parts.

The samplers are instructed to crush the coal and impurities at each stage in accordance with the sizes in the following table, as judged by the eye :

Weight of Sample to be Divided.	Approximate Largest Size of Coal and Dirt Allowable before Division.
1000 lbs.	1 in.
500 ,,	½ ,,
250 ,,	¼ ,,
125 ,,	⅛ ,,
60 ,,	¼ ,,
30 ,,	1/16 ,,

After the final reduction to about 7 lbs., the whole of the remainder is transferred to a special air-tight copper container, and conveyed to the laboratory accompanied by a ticket bearing the necessary particulars.

Each sample is air-dried after arrival at the laboratory, and the amount of free moisture estimated. It is then further crushed in a jaw-crusher, reduced by a riffle to about 1 lb., and ground in a specially-designed grinder, and the whole passed through a standard 60-mesh sieve. It is then well mixed, ready for analysis.

This method of collecting samples of run-of-mine gas coals might have to be modified in cases in which the proportion of large coal was greater—namely, pieces more than 9 in. or so in diameter. The use of a larger collecting bucket or ladle is not considered practicable, owing to the greater strain on the sampler, and the force with which the coal pours from the shoot. Any systems of collection must be designed to avoid over-taxing the endurance of the sampler, and be capable of being properly carried out under all conditions likely to arise by day or by night, and in all weather. Covered galvanized bins are used for storing part samples during collection in cases where two or more kinds of coal are being loaded in alternate batches, and it is necessary to collect two or more samples simultaneously.

When this method of sampling was being worked out, before full operation, the accuracy was tested by having two or more samples taken simultaneously from the same batch of coal. This check is still carried out from time to time. Two or more samplers collect, crush, and reduce samples independently. The results obtained from 26 such experiments were satisfactory from a practical point of view; and the deviation from the mean does not in any case exceed ± 1 p.ct. for the samples of 1000 lbs. This includes the total errors due to sampling and analysis; but the errors in ash determination are, of course, very small. The experiments were carried out on coals of various qualities, and the errors in samples of high-ash coals do not differ very much from those of lower ash content. For 750 lb. samples, the deviation from the mean does not exceed ± 1·32 p.ct. Utilizing these figures in the probability integral, it was calculated that only two samples in every hundred are likely to be out by more than 1 p.ct.

Discussion.

Dr. Henry Louis, in a written communication, stated that he had often tried to put sampling on a purely mathematical basis as a problem in probabilities, but so far had always had to abandon the attempt and fall back on rule-of-thumb methods derived from experience. He could not help thinking that a method of sampling which allowed errors of ± 1 p.ct. was not good enough as compared with the refined methods of laboratory analysis.

Dr. J. T. Dunn congratulated Mr. Walker on the large amount of work that had been accomplished on this important subject. The exact method of sampling was largely a question of practicability. He took many samples from trucks by the "hammer-and-shovel" method, and had found the results to agree remarkably well, considering the objections to that system. In one case a large sample of 23,000 lbs. was collected under special conditions, and another sample taken from the same batch by the hammer and shovel method. The results for the percentage of ash differed only by 0·2 p.ct.

Dr. W. B. Davidson remarked that he used the method of sampling described, and entirely agreed with what Mr. Walker had said. He would like to ask the author if he had dealt with cases of washed small coal.

Mr. Drury pointed out that "ladle" sampling was not satisfactory in cases where coals had been screened and "rough picked;" the larger material usually lying above the smaller in the same truck.

Mr. Hewson asked whether the sampling ladle was plunged right into the stream, or whether the portions were collected from the sides. What number of portions were collected from each truck?

Mr. Sensicle asked what Mr. Walker would do if a piece of stone 14 in. long was caught in the sample. If a piece this size was in a truck, it would be necessary to take the whole truck for a sample. The convention of reporting results of analysis to two or three decimal places still persisted, though the errors in sampling were as much as 1 p.ct., even with great care. Sometimes he had no option but to take his samples from trucks. He had adopted the method of breaking up all the coal in a section of each truck, and then taking portions from this section. This plan was fairly accurate, if the coal was homogeneous.

Major F. J. Bywater said he did not believe that a proper representative sample could be taken from the top of a truck. He hoped the Committee of the Fuel Research Board on sampling would not recommend any method of collecting samples from coal at rest in trucks.

The Chairman (Dr. G. Weyman) referred to the importance of training the sampler, by the methods described by Mr. Walker. He said it was a very difficult matter to sample coal in many gas-works, as the coal was usually mixed before crushing.

Mr. Walker replied briefly to the discussion. His samplers were instructed to plunge the ladle into the middle of the stream of coal. First runnings and small side trickles were avoided. Sampling from the tops of trucks was very unsatisfactory. Accidental agreement might occur in one or two cases. It was necessary to test any method of sampling by taking a large number of observations. It was often possible to reduce the weight of the gross sample in some cases, as with washed nuts, when the bulk was fairly homogeneous. As the diameter of the sampling ladle bucket was 9 in., it was not often that pieces of coal larger than this were caught. Larger pieces did get wedged into the bucket at times. Large pieces of stone were more easily picked out on the picking belts; and it was generally pieces up to about 4 in. in size which escaped detection. His aim was to plunge the bucket into the stream often enough to reduce to a minimum the chances of catching an unfair proportion of dirt. The picking-out of dirt, either from a sample or on the picking belts, was obviously a difficult matter. It was not always possible to tell at a glance whether a piece was dull coal or a bit of dirt band. At least two colliery companies had agreed to accept the method as fair.

Wales and Monmouthshire Institution.—The meeting of the Wales and Monmouthshire District Institution of Gas Engineers and Managers will take place at Porthcawl on the 28th inst., when Mr. H. D. Madden, of Cardiff, will read a paper on "General Sales Propaganda."

National Gas Council Meeting.—Arrangements have been made for the seventh annual general meeting of the National Gas Council of Great Britain and Ireland to be held at the Hotel Great Central, Marylebone Road, London, N.W., on Tuesday, May 26, at 11.30. The President (Mr. D. Milne Watson) will present the annual report and statement of accounts.

INCOME-TAX ALLOWANCES FOR WEAR AND TEAR OF GAS-WORKS PLANT—

INCLUDING METERS, PREPAYMENT METERS, GAS STOVES, FIRES, &c.

By W. M. Galleway, of Whitby.

[Before the North of England Gas Managers' Association, May 1]

In complying with the request of your Committee to give a paper at this meeting, the writer is desirous, if possible, of assisting the secretaries and managers of small or medium undertakings, who, like himself, are responsible for the administrative, as well as the productive, departments of a gas company. One of the largest items of standing charges consists of rates and taxes. This paper deals with the latter, of which income-tax forms the principal part.

Prior to the year 1912, gas undertakings were placed in an anomalous position as compared with electric lighting undertakings, for, whereas the former were not allowed any depreciation whatever, the latter were allowed depreciation at the rate of 3 p.ct. on cables and 5 p.ct. on plant and machinery. In that year, however, a special meeting of the Institution of Gas Engineers was held, at which, very appositely, Mr. Robert Shadbolt, the brother of our President, occupied the chair. As the result of that meeting a scheme was evolved which has been adopted by many undertakings.

The scheme is as follows:

GAS UNDERTAKINGS OTHER THAN THOSE OWNED BY MUNICIPAL OR OTHER PUBLIC AUTHORITIES.

Scheme for Determining the Income-Tax Allowances to be Granted for Wear and Tear and Maintenance.

Plant, Machinery, and Mains.

1. No depreciation shall be allowed in respect of the plant, machinery, and mains, other than as specified hereinafter; but *in lieu* thereof all expenditure on repairs and renewals is to be charged in the company's accounts for income-tax purposes and allowed as working expenses, as and when incurred. All expenditure on extensions and improvements, where debited against revenue, to be distinguished and excluded from the said allowances.
2. Provided that, whenever any expenditure on such renewals is incurred and full effect cannot be given to its deduction in the year when incurred, owing to the profits or gains chargeable with income-tax in such year being less than the amount so expended, the balance of the said expenditure which has not been allowed may be carried forward and allowed in the following year or years, as is provided in the case of unallowed wear and tear by section 26 (3) of the Finance Act, 1907.

Gasholders.

3. In addition to repairs, depreciation shall be allowed at the rate of 3 p.ct. per annum on the written-down value—such value not to include tanks, except where constructed of steel or iron; and in no case is the cost of excavation to be included in the value upon which the depreciation allowance is computed.

Meters (Ordinary and Prepayment), Cookers, and Gas Fires.

4. In addition to repairs, allowance for depreciation shall be granted at the rate of 10 p.ct. per annum on the written-down value.

Services and Fittings.

5. No depreciation shall be allowed in respect of services and fittings; but *in lieu* thereof all expenditure shall be allowed as a trading expense as and when incurred. "Services" are to be understood as representing the pipes which connect the street mains with the properties served. "Fittings" are the pipes, pendants, and brackets within such properties, supplied by and at the cost of the Company. Where fittings so supplied are removed by the Company at any time, they shall be brought back into stock, if of any value, and re-issued without any charge against revenue except for the cost of repairs necessary to enable them to be re-issued. In the event of their not being re-issued, revenue shall be credited with the scrap value.

General.

6. In all cases where depreciation allowances are granted, renewals, if charged against revenue, shall be carefully distinguished and notified to the surveyor, in order that they may be added back to profits for the purpose of arriving at the income-tax liability.
7. If new works are erected, wholly or partially, on a new site, in place of old works abandoned or demolished, a reasonable allowance shall be granted for renewals in respect of the displaced plant, so far as it is actually renewed—such allowance to have regard to the original cost of the displaced plant, *less* any depreciation that may have been granted, but such allowance shall not include the cost of preparing the new site or erecting foundations for the new plant.
8. All renewals of parts which do not destroy the identity of the original article shall be allowed as repairs, except so far as they constitute an extension, enlargement, or other similar improvement in value.
9. Where renewals are allowable under this scheme, *in lieu* of depreciation, they shall be allowed notwithstanding that the cost thereof may not have been debited in the Company's accounts against revenue.
10. "Written-down value" means original prime cost, *plus* subsequent additions (including renewals which have not been allowed for income-tax purposes), *less* all allowances actually granted for income-tax purposes in past years in respect of depreciation.
11. "Expenditure" includes the sum expended on materials, labour, and incidentals.
12. This scheme shall take effect for the year 1912-13 and future years, and for years preceding where claims of depreciation are now awaiting settlement.
13. Where in any case allowances for depreciation have been made which are now to be discontinued, and they have not been exhausted by renewals already effected, the amount of such unexhausted allowances shall be deducted from the expenditure on future renewals as and when they are effected.

We desire to adopt the above arrangements, and hereby undertake to fulfil the conditions thereof.

On behalf of.....

Dated the ..... day of ....., 191 .....

....., Chairman.

....., Secretary.

In 1915 the Directors of the Company I have the honour to serve decided to adopt the scheme; but before giving notice to the Income-Tax Surveyor to that effect, referred the matter to a Rating Association of which they were members, and submitted copious extracts of capital expenditure on gasholders, meters, cookers, and gas fires. The reply from the Association was to the following effect.

"The figures suggested for forming the basis of a claim are suitable ones, although our Surveyor questions whether the Surveyor of Taxes will accept them. It is however quite in accordance with the terms of the agreement, and should be contended for. It is possible that the Surveyor of Taxes may only offer to agree to commence depreciation at the present value, and that will then open-up the question of past depreciation. It must be remembered, however, that, by claiming depreciation of the first cost owing to no depreciation having been claimed or allowed in the past, you are starting your depreciation on a higher basis, and at a time when the rate in the pound has been increased. Our Surveyor questions whether the Commissioners would agree to open-up past depreciation which has been allowed, and at the same time agree to a scheme brought forward for the purpose of blotting-out the past and starting afresh with a uniform and agreed basis. Although no depreciation had been allowed in the past, the question might arise as to the charges which have been made to revenue for renewals and possibly additions; but of this we have no knowledge. Any dispute or claim which may arise would probably involve an investigation upon these points.

"Our Surveyor suggests that, assuming you are clear on the question of renewals and improvements charged to revenue, you should request the scheme to be put into action, and forward your claim to the Surveyor of Taxes, and await any counter suggestion. From experience which he has had of other cases, the scheme produces a result favourable to the Gas Company, and in such cases it would seem that the Commissioners have made a bad bargain."

Acting upon the suggestion, a request (accompanied with extracts from the ledgers showing the capital expenditure) was sent to the Surveyor of Taxes, together with the suggestion that the writer and an auditor of the Company should wait upon him, and produce evidence in support of the application. This, however, was declined, and a counter suggestion made that the Surveyor should call and inspect the Company's books. The result of this subsequent inspection was that the Surveyor admitted our claim, and the scheme was put into operation and worked until 1921 without any exception being taken by the Revenue Authorities, notwithstanding the fact that the allowances for wear and tear exceeded the amount of tax deducted for the interest and dividends paid annually to shareholders.

A new Inspector of Taxes was appointed for the district about this time, and to our surprise refused to allow depreciation at the rates to which the Company were entitled, and which they had been allowed from their adoption of the scheme; his contention being that the Directors were compelled by the Customs and Inland Revenue Act, 1888, section 24, sub-section (3), to pay over to the Commissioners of Inland Revenue the full amount of the tax deducted from dividends and interest paid to the debenture stockholders and shareholders from year to year, irrespective of any claim which the Directors had for depreciation. He intended in future to allow only a sum equal to the amount written-off annually for depreciation as shown in the statements of accounts.

The Directors contended they were entitled to the full allowance of 3 p.ct. and 10 p.ct. respectively on gasholders, meters, gas stoves, &c., which the scheme provided for; and as the allowances had been granted for several years without question, there was no reasonable ground for raising an objection to what had become an established precedent. As the question of depreciation allowance was a most important one, they decided to obtain expert opinion. This opinion was favourable to their view, but it was decided on the expert's advice to obtain Counsel's opinion also. Counsel having further confirmed the

Directors' contention, the Inspector's objection was withdrawn, and the scheme is still in operation.

Statement A shows the form of statement of liability submitted annually.

STATEMENT A.

Statement showing the Amount of Liability for Income-Tax, Schedule D.

	£	s.	d.	£	s.	d.
(1) Profit as per revenue account						
(2) *Add*:						
Depreciation on gas stoves, &c.						
Interest allowed by bankers (if any)						
(3) *Deduct*:						
Allowance under Finance Act, 1919, section 18						
Interest charged by bankers (if any)						
Schedule A (offices, &c.)						
(3a) Income-tax carried to credit of rates account						
(4) Allowance for wear and tear of gas-holders:						
Capital cost *less* previous allowances, £ at 3 p.ct.						
Allowance for wear and tear of meters, prepayment meters, gas stoves, and fires:						
Capital cost *less* previous allowances . £						
Add expenditure during current year						
£ at 10 p.ct.						
Net amount of liability for tax						

The amount of liability under Schedule D, item No. 1, requires no explanation.

Item No. 2.—The income-tax authorities claim tax on all sums written off through revenue account for depreciation.

Item No. 3.—Under the Finance Act, 1919, section 18, gas undertakings are allowed for repairs a sum equal to one-sixth of the value of the Company's buildings which contain machinery, which was agreed by the Surveyor of Taxes and ourselves at £240, with £40 per annum allowance.

Item No. 3a.—Income-tax account was in credit in consequence of the allowances being in excess of the amount of tax deducted from debenture interest and dividends; and as the Company were entitled to charge the full amount paid in rates, they claimed, and were allowed, the balance of income-tax credited to rates account.

Item No. 4.—Is self-explanatory.

Statement B shows the annual amounts allowed for wear and tear during the several years in which the scheme has operated.

STATEMENT B.

Amount of Allowances Received in the Several Years during which the Scheme has been in Operation.

—	Gross Amount of Taxable Profits after making necessary additions.	Allowance for Wear and Tear.	Net Amount of Taxable Profits.
	£	£	£
Year ending Dec. 31, 1915	2,354	1,137	1,217
" " " 1916	2,334	1,139	1,195
" " " 1917	2,118	1,048	1,070
" " " 1918	2,076	964	1,112
" " " 1919	2,171	887	1,284
" " " 1920	2,552	823	1,729
* " " " 1921	1,935	903	1,032
* " " " 1922	1,937	832	1,105
" " " 1923	3,983	691	3,292
" " " 1924	4,218	669	3,549
" " " 1925-26	3,430	645	2,785
	£29,108	£9,738	£19,370

* During these years the allowance was increased 50 p.ct. on gasholders—viz., 4½ p.ct. instead of 3 p.ct.

Statement B proves beyond question that the scheme confers substantial benefits upon the undertakings that have already adopted it; and those undertakings that are entitled thereto would, in our opinion, do well to give serious consideration as to whether it is not to their interest to claim the allowances which it grants.

Discussion.

The CHAIRMAN said the paper was another instance of the value of careful records. It would be of special interest to company undertakings.

Mr. HERBERT LEES mentioned that he was present at the meeting of the Institution of Gas Engineers when the scheme was discussed, and his recollection of it was that those present were by no means unanimous as to its benefits to the gas industry. He adopted the system and it worked well.

Mr. T. P. RIDLEY (Newcastle) remarked that his Company had adopted the scheme.

Mr. NORMAN S. COX did not think the scheme was to the advantage of the industry. His Company had not adopted it.

Mr. R. WOOD (Barnard Castle) said that his Company had adopted the scheme to advantage.

NEW COLLIER FOR THE SOUTH METROPOLITAN GAS COMPANY.

On Saturday last, May 9, the s.s. "Redriff" was launched for the South Metropolitan Gas Company from the yards of the Tyne Iron and Shipbuilding Company, Ltd., at Willington Quay-on-Tyne. She is a sister ship to the s.s. "Camberwell," which was launched from the same yard early last year, and which has given great satisfaction in the service of the Company. The two ships are of a type specially designed to carry coal from the Tyne to the Company's gas-works on the Thames. The total deadweight is 2435 tons, on a mean draft of about 18 ft. 2 in. The length between perpendiculars is 244 ft., breadth moulded 36 ft. 6 in., and depth moulded 20 ft. 6 in.

The launch was carried out with complete smoothness; and the christening ceremony was performed, as the ship started on her journey down the ways, by Mrs. Frank Jones, wife of the Vice-President of the Company. It had been anticipated that the naming would be performed by Mrs. C. C. Carpenter, and Mr. Jones later referred to the unfortunate inability of the President and his wife to be present after all. The large company, while greatly regretting her absence, would assure Mrs. Carpenter that the bottle was gracefully, but very efficiently, broken by her substitute. The traditional christening by wine was quite unnecessarily supplemented by a drenching thunder shower of unusual violence—the only one of the day—which began as the party mounted the platform, and ceased exactly as the ship reached the water.

The company then adjourned to the moulding loft (which was gaily decorated with nautical flags) for tea as the guests of the shipbuilders. The good ship was toasted, after which Mr. G. F. Mulherion (the Chairman) gave the health of the South Metropolitan Gas Company, coupled with the name of Mr. Frank Jones, to which the latter replied.

Afterwards Mr. Jones proposed the health of the Tyne Iron and Shipbuilding Company, Ltd. It was a sad sight, he said, to see the endless succession of idle yards on both banks of the river, and one could only hope that times would change.

Mr. Mulherion, in reply, enlarged on the serious position of British shipbuilding. To him it was very questionable whether the Government should allow British owners to send orders to the Continent for ships which could be delivered duty free. The boat just launched was the last order his firm had; and it was a terrible blow to him that his men should have no further prospect of work, while nothing was being done to prevent orders from going abroad.

Mr. Mulherion then presented a souvenir of the occasion to Mrs. Jones, who returned thanks in an appropriate and graceful speech.

Other toasts were the North-Eastern Marine Engineering Company, Ltd., who are supplying the engines for the boat, and Commander T. C. Anderson, R.N., Marine Superintendent of the South Metropolitan Gas Company, who paid a warm tribute to the workmanship, from top to bottom, of the Shipbuilding Company.

Among those present were Major F. J. Bywater, M.C. (the South Metropolitan Gas Company's representative in Newcastle), and Mrs. Bywater, Mr. T. Curr (Chief Engineer, East Greenwich), Mr. T. S. F. Gibson (Chief Constructional Engineer), Mr. R. C. Macdonald (Chief Mechanical Engineer), Mr. L. M. Boyce (Chief Engineering Clerk), Mr. F. P. Tarratt (Chief Engineer of the Newcastle and Gateshead Gas Company) and Mrs. Tarratt, Mr. T. P. Ridley (Secretary of the latter Company), and Mrs. Walter King, widow of the late Editor and former proprietor of the "JOURNAL."

Birkenhead Gas Undertaking.—Speaking at a meeting of the Claughton Ward Conservative Association, Councillor S. Woodward said that under the chairmanship of Mr. Luke Lees the gas undertaking at Birkenhead had been changed entirely. The extensions had cost £200,000; and in view of the development of electricity, some people asked whether they were wise in expending such an amount. Experience had proved that the Gas Committee were justified in their action, for last year they had produced 1200 million c.ft. of gas, compared with 1104 millions in 1913—an increase of 5·7 p.ct. This showed that the gas undertaking had a great future before it. They had reduced the price to 3s. per 1000 c.ft., which compared very favourably with towns similarly situated. Had not the price of residuals fallen so much, the price of gas would have been reduced even further. He invited the ratepayers to visit the gas-works and see for themselves what had been done on their behalf in their own undertaking.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Low C.V. Gas and the Unaccounted-for Percentage.

Sir,—It is unfortunate that Mr. West should mar an otherwise excellent address [see "Journal" for April 22, p. 237] by an unjustifiable condemnation of gas of 410 B.Th.U. per c.ft. value. The harmful effects of NH_3, O_2, HCN, H_2S, and SO_2 on meters and mains have been fully dealt with by the Gas Investigation Committee, and do not require further emphasis.

Mr. West stated that, for several years before he took charge, unpurified gas was being delivered to the town; and in the very next breath he said that low-grade gas was to blame for the drying of diaphragms and pitting of meters and mains. Coming from such a tainted source as Newark, the condemnation was discounted in its nativity. We should, however, be better pleased, and it would be a lesson to gas engineers to be certain of their facts before rushing into print, if the Technical Press were much more aggressive in their criticism of such ridiculous statements.

The difference in the unaccounted-for gas when sending out 410 and 475 B.Th.U. is merely a coincidence peculiar to Newark. The distribution of gas of low calorific value had nothing whatever to do with it. For the past ten years we in Greenock have been sending out gas of low calorific value. Our declared value is 410, and our average unaccounted-for gas during the period under review is 3·19 p.ct. Another important point is the cost of meter repairs; and if low-grade gas has the harmful effects attributed to it, one would expect the cost of these in our case to be much higher than in places where high calorific value gas is supplied. But a glance at the "Gas World" Analysis of Corporation Accounts does not show this to be the case. We have been through private meter repairing establishments and have examined meters stated to be from districts supplied with 475-500 gas; and their condition was a positive disgrace to the industry. Indeed, our meter repair bill is so normal that we feel that meter makers, in continuing to guarantee meters, are wronging those who, like ourselves, supply clean gas with a minimum of inerts. That portion of the cost of a meter due to the "guarantee" clause must be considerable; and it would be interesting to know who are getting the benefit of it. We are not.

We have examined meters which have been in use with 410 B.Th.U. gas for seven and ten years, and find the leather diaphragms are in excellent condition and show no sign of drying. The tin casings of the dry meters are quite as good as those of meters used for the same length of time with 500 gas.

The secret of the efficient use of town gas—its effect upon meters, &c.—lies in its purity and low inert content.

Low-Temperature Gas and Gas from Low-Grade Coal.

Sir,—I was glad to read the articles on this subject which appeared in some of the daily papers last week. Without doubt valuable work is being done at the Government Research Station. The satisfactory production of good smokeless fuel should open up new markets in those Mediterranean countries where charcoal fires are still in vogue. Wood is mostly dear and scarce, so a suitably-produced smokeless fuel, which is an excellent substitute for charcoal, should find a ready and profitable market. For the home market to compete with coal for domestic purposes, smokeless fuel will need to be available at competitive prices. The most economic place to produce fuel is, as a rule, where there is a profitable market not only for the fuel itself, but for the rich gas obtained from the low-temperature process of carbonization. In most cases this will be found to be the existing gas-works throughout the country; and if the Fuel Research Board, as a result of their excellent work, can show that the installation of the necessary plant is a sound proposition for gas undertakings, they will have rendered a great national service.

In conjunction with this proposition, consideration should also be given to the question of installing suitable plant at the pit-head, for the complete gasification of such low-grade coal as will not economically bear the heavy cost of transport. The gas so produced could with ease be sent out by high-pressure pipelines to the different gas undertakings, where, mixed with low-temperature gas, or alone, it would meet all the requirements of a public gas supply.

Being sent out at high pressure, the mains involved would not be large, and in numerous cases they could be laid along the canals to the towns *en route*, and so save even the opening-up of roads. In America a similar arrangement of pit-head plant is being installed, and the gas produced is to be sent under pressure as far as 50 miles, for breaking down or supplementing natural gas supplies, which are becoming exhausted.

Special Orders and the One-Half Proportion.

Sir,—In your editorial notes regarding the Aldershot Special Order you appear to have overlooked the fact that the extension of borrowing powers to one-half the amount of the share capital is a common clause in Special Orders. The novelty of the Aldershot application lies in the fact that it is the first application for such temporary powers under the Public Utility Companies (Capital Issues) Act to be made permanent.

Hiring Charges and Installation Delays.

Sir,—I have read Mr. Quigley's tirade about "gas companies of the Metropolis;" and as a hirer from one of the largest for the past thirty years, please allow me to enter my protest, and to say that, if consumers only take the trouble to send their complaints to the proper quarter (the head office), they will find every attention will be given to them, with the utmost civility.

At present I am a prepayment consumer; and here is a recent experience. I did not consider that I was getting as good a result as I should from the gas, so I wrote to the Company. The next morning I received a letter asking me to arrange my own time with an inspector, which I did. The interview took place, and within a fortnight the workmen were busy re-carcassing the house, with the result that I had four extra burners put in, and highly satisfactory lighting. A gas fire was installed, and the two cooking stoves were replaced by a larger one and a gas ring—much to the joy of the female section of my household.

And here is where an adequate response to legitimate complaint benefits alike consumer and Company. My brother came to see me, and at once wanted to know all about the beautiful light. I told him; with the result that he, being an ordinary consumer, purchased a gas fire for each of his rooms. My son did the same. All this means increased comfort and cleanliness and labour saved in three homes, and a greater consumption of gas for the Company.

The fact seems to me to be that your correspondent wrote to you instead of to his Gas Company. During my experience of Metropolitan Gas Companies, I have never once had to complain of the delays Mr. Quigley says he finds exist in his area; but, of course, one must be reasonable. Gas companies, like other industrial concerns, have their difficulties; but they are not slow to appreciate them, which is to the advantage of themselves and their industry, and for the comfort and convenience of their consumers.

Consumer.

Brockley, S.E., May 5, 1925.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

Bills read a second time, and committed: Barrow-in-Furness Corporation, Bolton Corporation, Gas Light and Coke Company.

Bill reported, with amendments: Uckfield Gas and Electricity.

The further Standing Orders applicable to the following Bills have been complied with: Barrow-in-Furness Corporation, Bolton Corporation, Gas Light and Coke Company.

Gas Regulation Act.

On the motion of Viscount Peel, the draft Special Orders relating to the Brighouse Corporation, Pinner Gas Company, and the Yeadon and Guiseley Gaslight and Coke Company have been approved.

HOUSE OF COMMONS.

Progress of Bills.

The Statutory Gas Companies (Electricity Supply Powers) Bill has been reported from Standing Committee C, without amendment.

Bill read a second time, and committed: Hoylake and West Kirby Urban District Council.

Gas Regulation Act.

The draft Special Orders relating to the East Grinstead Gas and Water Company, Monmouth Gas and Water Works Company, and the Slough Gas and Coke Company were approved on the motion of Sir Burton Chadwick; and the Brighouse Corporation, Pinner Gas Company, and the Yeadon and Guiseley Gaslight and Coke Company Special Orders were also agreed to, on the motion of Colonel Moore-Brabazon.

Smokeless Fuel.

Sir Henry Slesser asked the Prime Minister, in view of the reports on the quality of the smokeless fuel produced by the low-temperature carbonization process, and consequent elimination of the smoke nuisance if it were universally employed for household fuel, if the Government would give facilities for bringing an Act into force providing for the compulsory carbonization of bituminous coal before use.

Mr. Baldwin, in reply, said that as soon as the Government are satisfied that these processes can be operated successfully on a commercial scale, they will consider the steps to be taken to achieve the object which all desire.

SOUTH METROPOLITAN GAS BILL.

HOUSE OF COMMONS COMMITTEE—Tuesday, May 5.

(*Before Colonel* Wheeler (*Chairman*), *Mr.* Cecil Wilson, *Mr.* Hanbury, *and Colonel* Heneage.)

The object of the Bill is to allow agreements to be made between the South Metropolitan Gas Company and other gas undertakers for mutual assistance. The only petitioners were the London County Council, who did not object to the proposals in the Bill, but asked that provisions should be made for the revision of the Company's basic price, which was granted by Parliament in 1920, there having been inserted in the Company's Act of 1920 a clause binding the Company to give an opportunity for revision within five years.

The promoters of the present Bill were represented by Mr. H. P. M'Millan, K.C., Sir Lynden Macassey, K.C., Mr. W. E.

Tyldesley Jones, K.C., Mr. Rowand Harker, and Mr. F. J. Wrottesley. The London County Council were represented by Mr. Jacques Abady.

Mr. H. P. M'Millan, K.C., in his opening statement, traced the history of the Company, in order to show how progressive had been the policy pursued. At the present time they supplied a population of between 1½ and 2 million people. The area of supply covered 52 square miles. There were 1340 miles of mains, and 400,000 meters. Gas was supplied within the territory of ten metropolitan boroughs, and three urban district councils outside London, and the Company employed 8000 workpeople. The capital amounted to 6½ millions of ordinary stock, and there was about 2½ millions of loan capital. There were 18,000 shareholders, and between £400,000 and £500,000 of the Company's stock was held by the workmen. Counsel then went on to discuss the resources of the Company (which, together with the proposals of the Bill, were set out in the "Journal" for Dec. 24, 1924, p. 842), and said that it was proposed that those resources should be used to the mutual advantage of this Company and the gas companies which abutted on to its area of supply. These were the South Suburban, the Croydon, the Wandsworth, Wimbledon and Epsom District, the Gas Light and Coke, and the Commercial Gas Companies. The powers sought were carefully hedged with limitations. In addition to the limitation that agreements for mutual assistance could only be entered into with statutory companies supplying in areas adjacent to the South Metropolitan Company's area, it was provided that the agreements must be subject to the approval of the Board of Trade. The particulars of any agreements entered into must be submitted to the London County Council, who were entitled to make representations to the Board of Trade, while local authorities affected, who were outside the County area, could also make representations. There was a clause to protect the Port of London Authority in connection with agreements which affected river accommodation. At present the South Metropolitan Company had power to amalgamate with any of the adjacent companies mentioned. The present proposals were considerably short of amalgamation, however, because that was not regarded as practicable or feasible at the present moment. There were several difficulties. The different companies had varying schemes of co-partnership, benefit funds, superannuation funds, and so on, the amalgamation of which would present considerable difficulty. Again, the prices of gas varied, and amalgamation might involve the continuance of differential prices, and consequent discontent, while the districts themselves to some extent varied in character. Very similar arrangements to those proposed in the Bill had received the sanction of Parliament in the case of electricity companies. The present proposals had undergone the scrutiny of the local authorities and others interested, and apparently had elicited only approval.

Coming to the opposition of the London County Council, he said that up to 1920 the legislation governing the Company might be said to have proceeded generally on the lines of that of the other London gas companies. In 1920, however, Parliament had sanctioned a new departure in the matter of charging for gas. The South Metropolitan Gas Company's Act of 1920 had established the heat unit basis for charging for gas supplied, and had established a new method of regulating the price of gas, and for applying the profits of the Company. The Bill had encountered considerable opposition when it was promoted in 1920. It had been opposed by the City of London Corporation, the London County Council, and by eight Metropolitan boroughs, and was also confronted with an adverse report by the Board of Trade. The general ground of that opposition was that the Company should await general legislation, which was then contemplated, and should not proceed with a Bill on their own lines. The House of Lords Committee before whom the Bill came had decided that, notwithstanding this opposition, the Bill should be considered, and, after hearing evidence, had allowed the Bill to proceed. But there had been inserted in that Bill, by agreement with the Company, a clause providing that the Company should, not later than the 1925 session, promote a Bill in Parliament proposing a revision of the provisions of the Act as to basic price, or giving an opportunity for such revision to be made. It was provided that the London County Council and the council of any metropolitan borough or urban district within or partly within the limits of supply of the Company should be entitled to be heard on such Bill. Thus, said Counsel, the present Bill gave the opportunity for a revision of the basic-price system. At present neither the City Corporation nor the eight metropolitan boroughs had any criticism to make, and there was no report from the Board of Trade. The Company's Act of 1920 enabled them to charge for gas on the heat value basis, and to introduce a system of charging which involved a basic price, and a system of participation in profits by consumers, shareholders, and worker co-partners in certain prescribed proportions. The basic price fixed by that Act was 11d. per therm, and the basic dividend was 5 p.ct.

The London County Council had taken advantage of the fact that the Company were in Parliament (as they were bound to be) in order to criticize the scheme; and this was quite legitimate. The Council submitted that the time had now come when uniform procedure should regulate the revision of the powers of charging of all gas companies supplying in the county; and they objected to the present Bill being passed unless provisions were inserted enabling the Board of Trade, at any time, on the application of the Company or the petitioners, to make an Order revising the powers of charging authorized by the Company's Act of 1920; or, alternatively, unless provisions were inserted reducing the basic price of gas fixed by the said Act and providing for the future regulation of such powers. Thus, said Counsel, the petition of the London County Council was simply that the Company ought now to be brought under the general legislation, and that the special provisions which had been sanctioned by Parliament in 1920, in recognition of the Company's merits, and the merits of their system, should be abrogated. The present proposal was that the basic price of 11d. per therm should be revised. Counsel submitted that the experience of the past five years had shown that Parliament were exceedingly wise in granting the basic price of 11d., which had been operated with great fairness and moderation by the Company. The working of the scheme had shown that the margin between the selling price and basic price had never been excessive. The elasticity of the system had been proved to be not greater than ought to be accorded to a well-conducted company; and he suggested that the margin ought to be considerably greater now than it was before the war. If the Company had been subject to the general legislation, instead of to the provisions of their own Act, they would have been entitled to a standard price in excess of 11d. The Gas Regulation Act was rather a dividend-protecting measure than anything else, and could not compare with the South Metropolitan Company's scheme, which had worked so admirably, and was not criticized by the consumers. Yet it was suggested that, for the sake of uniformity, the Company should be subjected to the provisions of the Gas Regulation Act. His submission was that experience had justified both the basic price of 11d. and the operation of the scheme to which that basic price was related, and that if the Company had been working under the general Act, the results would have been in no way so advantageous to the parties concerned. Also, as a matter of Parliamentary practice, it was an unheard-of thing to subject a Company, against their wish, to a code which, so far as all other companies were concerned, was merely optional. The Company looked upon this matter with some concern from the point of view of their working co-partners. The confidence of the workpeople, and the friendly relations existing, had been one of the greatest assets of the Company, and had been to the advantage of the public. He asked the Committee not to disturb that confidence.

Dr. *Charles Carpenter* (President of the Company, and Chairman of the Board of Directors) then gave evidence, and supported Counsel's statement. The proposals of the Bill were in the public interest; and because they were in the public interest, they were also in the interests of the Company.

His evidence concerning the trend of gas legislation, with regard to the methods of charging for gas, was interrupted by the adjournment of the Committee until Wednesday.

Wednesday, May 6.

Dr. *Carpenter* resumed his evidence, and said that, up to the time of the war, when the old sliding-scale was in existence, the then state of affairs was satisfactory. The most important principle was that the control of gas undertakings must be from within, and not from without; and this was the principle of the old sliding-scale. Due to the war, however, the old sliding-scale principle broke down; but it was inexpedient that there should be any control of prices by an outside authority. The Temporary Charges Act of 1918 was merely a stop-gap, and operated only to a limited extent. At the close of the war, therefore, it was necessary to review the whole position. In doing this there were three main matters—(1) the financial question, (2) the great advance on the technical side of the gas industry consequent on the work of the Fuel Research Board, and particularly that of Sir George Beilby, and (3) the question of still further improving the relationship between the Company and its employees. These matters were correlated, for not only had the old sliding-scale broken down as regards the shareholders, but it had failed as regards the workpeople. The great bulk of labour, he believed, did not object to capital getting a fair return, any more than capital objected to labour receiving a fair wage. While it might be arranged that capital and labour received a fair return, this did not meet the requirements of the consumer, because it might leave capital and labour with no incentive to put forth any greater efforts to improve the position of the consumer. Therefore, the basic-price system was devised. The South Metropolitan Company made the recommendations of Sir George Beilby and the Fuel Research Board, as to charging for gas by its heat value, the basis of its Bill of 1920. At the same time they did not proceed on the basis of the Gas Regulation Act of 1920—viz., to secure from the Board of Trade a therm price based on the increased cost of manufacture since 1914. The Company asked for an increase in the standard dividend from 4 p.ct. to 6 p.ct.; but Parliament decided the increase should be to 5 p.ct. A basic price of 11d. per therm was asked for and obtained. As a result of the experience with the basic-price scheme, he asked Parliament to allow the Company to continue under the scheme of their own Act of 1920, which was passed by Parliament in the face of opposition by a large number of local authorities and also an adverse report by the Board of Trade. That Act, for the first time, as regards co-partnership, enabled Labour to share on equal terms with Capital in the prosperity of the Company. The London County Council, concerning the present Bill, desired that the Company should not be allowed to continue in the exceptional position in which they had been placed by their Act of 1920. The Council first contended that the basic price of 11d. should be lowered, and also that the Company should be subject to revision upon the terms of the Gas Regulation Act of 1920. As regards the first, the margin available with the present basic price was only sufficient to allow the system to work satisfactorily. In the second place, Dr. Carpenter said he objected to revision by an outside authority who were not in a position to know what price should be charged. The margin at present between the basic price and the price charged was 2¾d., which was not more than enough to enable the Company to carry on the undertaking in a manner which would produce the best results. The benefit to the Company and the workpeople could only accrue if the price charged was less than the basic; and if a lower figure than 11d. were fixed, it would mean that neither the shareholders nor the workpeople would get anything worth having out of the basic price scheme. Apart from the suggested revision of the basic price of 11d., Dr. Carpenter said he objected to automatic revision, by which the Company would have to go through a particular performance whether there were good reasons or not. The Company were in Parliament with Bills sufficiently often to give Parliament full control over the Company. In 1920, when Parliament passed the Company's Bill, it was arranged that the Company should come to Parliament in five years, and give an account of their stewardship under the basic-price system. This was what they were now doing. He objected to the operations of his Company being sterilized by automatic machinery.

Mr. Jacques Abady then cross-examined on behalf of the London County Council.

Witness agreed that if the Company were successful in its present application, there would be no provision for revision of the basic price.

COUNSEL then explained that there was no intention on the part of the County Council to suggest that the basic price scheme should be altered. They asked that a clause should be inserted in this Bill giving the Board of Trade power to revise the basic price—not to alter it to the sliding-scale with a standard price—at any time, on application by the Council or the Company, but not so as to deprive the Company—*i.e.*, the shareholders or co-partners—of any benefit to which they might be entitled by reason of economy or good management.

Witness: My first question as a layman is: "Where is the snag?"

COUNSEL: There is no snag.

Witness: Then the answer is that I do not want the Board of Trade brought into this matter, directly or indirectly. I think Parliament are competent.

COUNSEL said the case for the London County Council was that revision of the 11d. basic price was due, and that if the Committee did not revise it in this Bill, and provide for revision in the future, then a clause should be inserted providing for periodical revision.

In the course of further cross-examination, it was put to the witness that a revision of the basic price would not interfere in any way with the new position of the employees as regards co-partnership under the Company's Act of 1920. Dr. Carpenter, however, contended that, inasmuch as any reduction would set back the point from which the benefit to the co-partners would start, the whole basis of the 1920 scheme would be seriously interfered with. The possibility of periodical reduction would be a violation of the principle of the Company's Act of 1920, upon which the workpeople had been treated since that Act was passed.

It was suggested by Mr. Abady that, so far as the incentive to reduce prices was concerned, the sliding-scale worked in the same way as the basic-price system; but Dr. Carpenter maintained that the sliding-scale would never have done for the South Metropolitan Company what the provisions of the 1920 Act had done.

Mr. ABADY wanted to know why the South Metropolitan Company objected to the clause which the London County Council asked should be inserted, when there was nothing in that clause which affected the Company.

Dr. *Carpenter* replied that one of his great objections to control by the Board of Trade was that it was possible, under the Gas Regulation Act, to fix a standard price for gas in London, which would do an enormous amount of mischief in increasing the price of gas to the consumer.

COUNSEL, dealing with the alterations in the Company's position brought about by the 1920 Act, said that the Act enabled the Company to distribute 5 p.ct. instead of 4 p.ct. to the shareholders without decreasing the price of gas, and allowed the 5 p.ct. to be distributed however high the selling price of gas. Also, he said, it enabled the increment to the shareholders over and above 5 p.ct., in respect of each price reduction, to be increased from £8813 to £11,000. It had given the co-partners a statutory right to a share, but it had enabled the shareholders to take 1 p.ct. more profit than previously, before the co-partners received anything.

Witness said that what it had done was to restore to capital what had been already restored to labour. Labour had had its standard wages raised in accordance with the post-war conditions, and so capital had had its standard raised in accordance with the changed conditions.

COUNSEL remarked that the scheme also enabled the point at which benefits were derived to depend not upon the price of gas to the ordinary consumer, but on the average price to all consumers, which was an advantage to the shareholder, because the average price was a lower figure than the price to the ordinary consumer.

Dealing with the clause suggested by the London County Council, and the provisions of the Gas Regulation Act, Mr. Abady said there was nothing in the clause submitted by the Council which would deprive the South Metropolitan Company of the benefit of any reduction in cost due to efficiency. If the reduction were due to efficiency, it was due to a cause within the control of the Company; and it was only in respect of reductions arising from circumstances beyond the control of the Company that the Board of Trade, under this clause or under the Gas Regulation Act, had power to make reductions in price. He maintained that in 1920, when the Company's Bill was before Parliament, the Company's Counsel had offered the revision of the basic price by a competent tribunal, if the London County Council pressed the point that 11d. was too high.

Dealing with the basic price of the South Metropolitan Company and the standard prices of the Gas Light and Coke Company and the Commercial Gas Company, Counsel said that, when the basic price of the South Metropolitan Company was fixed, prices were not at their peak, and they had applied for a 5 p.ct. dividend, which they were sure of, so long as they had the revenue, however much the price of gas increased. The Gas Light and Coke Company and the Commercial Company had applied for a standard price under the Gas Regulation Act at a later date, when prices were very high indeed, and, consequently, their standard prices were much higher. Also, as they were under the provisions of the Temporary Increase of Charges Act, and were deprived of their full dividends for a longer period than the South Metropolitan Company, their standard prices were fixed higher.

Witness said that, if the standard prices were fixed on the basis that the Gas Light and Coke Company and the Commercial Gas Company had had a reduced dividend for a longer period than the South Metropolitan Company, he should say that the Board of Trade had exceeded their powers.

COUNSEL then pointed out that the Gas Light and Coke Company had a co-partnership scheme, and that for every 1 p.ct. dividend paid to the shareholders the workmen received a certain amount.

Witness said that the distribution did not take into account the advances in wages made since 1914.

COUNSEL mentioned that in 1923 the co-partners of the Gas Light and Coke Company had received £63,666, and in 1924 £71,794, though the reduced standard price of 11d. was operating in the latter year. Did this show that the powers of the Board of Trade operated to reduce the workmen's share, as had been suggested?

Witness remarked that, though the amount distributed was increased, there were twice as many men to share the higher figure as there were to share the lower amount.

COUNSEL said that in 19 cases out of 20, when Parliament had fixed a standard price, that price was fixed under economic conditions which were more or less stable; and he obtained an admission from Dr. Carpenter that in 1920 economic conditions were not stable.

Mr. ROWAND HARKER, re-examining Dr. Carpenter, said that the clause in the 1920 Act of the Company relating to revision made no reference to any tribunal other than Parliament. The Company's attitude was that, if there were to be a revision of the basic price, they asked this Committee to consider whether the 11d. was to-day the right and proper basic price, rather than that the suggestion of the County Council, referring the matter to the Board of Trade, should be acceded to.

Dr. *Carpenter* agreed, and said that in 1920 the Company had never contemplated the possibility of periodic revision.

The Committee adjourned until Thursday.

THE COMMITTEE'S DECISION.

The Committee continued consideration of the Bill on Thursday and Friday. On the conclusion of the Company's case, Mr. Abady addressed the Committee on behalf of the London County Council, after which,

The CHAIRMAN said the Committee had come to the decision that the basic rate of 11d. was justified at the present time. This was their view from what they had heard during the proceedings. The Committee did not propose to insert the clause asked for by the London County Council bringing the Company under the revision of price clauses of the Gas Regulation Act; but a clause similar to clause 27 of the Company's Act of 1920 would be inserted, by which the Company would be compelled to come to Parliament in 1935 in order that there should be an opportunity of revision then. It was to be made clear, however, that this did not mean that there must necessarily be a revision, but that there would be an opportunity for revision if the circumstances warranted.

Mr. ABADY intimated that the London County Council might decide not to take any part in drafting the new clause, with a view to opposing in the next House.

The Committee then adjourned until Wednesday, May 13, when the promoters promised to bring-up a clause to give effect to the Committee's decision.

NEWPORT CORPORATION BILL.

When this Bill came before the Local Legislation Committee of the House of Commons, presided over by Colonel Sir JOSEPH NALL, last week, there was opposition by the Newport Gas Company, with respect to a clause giving the Corporation power to develop and lease lands; the Company's object being to prevent the Corporation leasing buildings on those lands, and binding the tenants not to use gas.

Mr. F. N. KEEN, representing the Corporation, said that all the Corporation were asking was that they might have power to lay-out and develop certain lands that they acquired, and to lease those lands, or part with them in other ways. They were not seeking to diminish the rights given to the Gas Company by Parliament to supply gas to all who wished to take a supply. It was suggested by the Gas Company that the Committee should add a proviso to the clause in question, to the effect that the Corporation should not make or impose, under the powers of this section, any term, condition, or restriction with respect to the form of light, heat, power, or energy to be used in any building or on any lands, or with respect to the taking from any particular local authority, company, body, or person of any form of light, heat, power, or energy.

COUNSEL, in reply to Mr. Neville (a member of the Committee), said that the electricity undertaking in Newport was carried on by the Corporation, and the Gas Company were apprehensive that, in developing buildings upon the lands which the Corporation acquired, and leasing them to tenants, they might impose some restriction confining the tenants to the use of electricity instead of gas.

Mr. *O. T. Morgan* (Town Clerk), in evidence, said that the Corporation had no intention of treating the Gas Company unjustly, and the latter could not complain that in the past the Corporation had treated them unjustly.

Witness, cross-examined by Mr. Rowand Harker (who represented the Gas Company), agreed that in the case of certain housing estates the Corporation had insisted upon the tenants of those properties entering into an agreement in which there was a clause providing that the tenants were not to use gas for the purpose of lighting.

Witness, in re-examination, referred to one of the estates, which was acquired under the Housing Acts for the erection of working-class dwellings. In August, 1920, in connection with the supply to this estate, the Gas Company had written asking that for each house supplied with a complete installation of gas lighting (five points), cooker, and wash boiler, the housing authority should contribute £12 10s. towards the installation costs, the gas appliances remaining the property of the Gas Company. In the event of the Corporation being prepared to give the whole of the public lighting of the estate to the Gas Company for a period of not less than twelve years, the housing authority would be asked to contribute £11 10s. per house only, the appliances remaining the property of the Gas Company. The Corporation had had an offer from the Electricity Department to lay all services and the lines on the estate, but the electricity undertaking required a guaranteed payment of £1000 a year until the revenue from the supply of current amounted to that sum. The facts had been laid before the Housing Committee, and, on the advice of the Housing Commissioner, the Committee had accepted the offer of the Electricity Department. One of the terms of the offer was that electricity only should be used for lighting the houses.

Witness, in reply to the Chairman, said that the clause did not prevent gas stoves being installed. The Corporation, he said, had not

imposed the condition referred to without consulting the Housing Commissioner.

The Chairman said it was surely outside the scope of the Housing Commissioner as to whether any ordinary citizen should be prevented, by the imposition of some unreasonable clause in an agreement, from using such kind of light or heat as he might wish to use.

Witness pointed out that the condition was part of the terms offered to the Corporation, and, in reply to Counsel, said the apprehension of the Housing Committee was that, if they accepted the offer of the Gas Company, it would make the housing estate more burdensome than if electricity were installed by the Corporation.

In regard to another housing estate it was put to witness that the Corporation had never even approached the Gas Company; and the reason he gave was that it was assumed the same terms would be applicable.

Major Colfox (a member of the Committee) ascertained that there were both electricity and gas mains very near to the sites with which the present Bill was concerned, so that there was no question of having to incur the cost of laying new mains, and there would be no capital cost to be borne by the gas or electricity undertaking. Therefore, there would not be any very great disparity of price between electricity and gas, and there would be no objection, from the tenant's point of view, to having the proviso suggested by the Gas Company inserted in the Bill.

Witness said he did not suppose for a moment that the Corporation would think of imposing such a restriction in these cases; but, at the same time, they did not want a precedent created by the insertion of this proviso.

Major Colfox, dealing with the prohibition of gas for lighting in the housing estates previously referred to, said that the Corporation, in the person of the electricity undertaking, wished to make the Corporation, in the person of the Housing Committee, give them a monopoly.

Witness disagreed, and said that those were the terms upon which the electricity undertaking were prepared to supply; and the Housing Committee had not accepted those terms until they had consulted the Ministry of Health through the Housing Commissioner.

Mr. *A. N. Moore* (Electrical Engineer) said the Electricity Committee's request that the Gas Company should not be allowed to supply gas for lighting purposes was for the reason that, unless the Electricity Committee could be assured of a reasonable return on their capital expenditure for lighting purposes, they would not be able to justify their expenditure as part of their general balance-sheet.

Cross-examined by Mr. Harker, witness said he was not aware that the question of restricting tenants with regard to the use of gas applied to other premises besides the housing estates referred to. Mr. Harker mentioned, however, the case of a refreshment room, which was Corporation property, where the tenant desired to have a gas cooker, and suggested that the Corporation had refused to allow a gas cooker to be installed, but had insisted upon the tenant having an electric cooker. Witness said he knew nothing about this.

After the Committee had conferred, the Chairman said they did not think they need pursue the Gas Company's petition further. Their decision was that the proviso should be added to the clause.

STATUTORY COMPANIES (ELECTRICITY SUPPLY POWERS) BILL.

This Private Member's Bill, promoted by Mr. Clarry in the House of Commons, was disposed of in less than five minutes by a Standing Committee of the House on Tuesday, May 5.

There were no amendments, and the Bill was reported to the House accordingly. The Bill, as we have already pointed out, removes the present disability on gas companies, and enables them to apply direct to the Electricity Commissioners for Electric Lighting Provisional Orders, and to apply their capital for the purposes of working such electricity powers.

The next stage is third reading.

UCKFIELD GAS AND ELECTRICITY BILL.

The Unopposed Committee of the House of Lords have ordered this Bill to be reported for third reading. Its purpose is to incorporate and confer powers upon the Uckfield Gas and Electricity Company; and its main provisions were set out in the "Journal" for Jan. 28, p. 210.

A number of amendments have been made. In the first place, the incorporation of the Company is to take place as from Jan. 1, 1926, instead of Oct. 1, 1925. Also, meetings are to be held yearly in March, instead of June.

With regard to Directors, the number is to be six, but it can be varied so that there are not more than seven or less than five. The qualification of a Director is to be the possession, in his own right or in the joint right of himself and another, of stock to the nominal amount of not less than £100; but a proviso has been added to the clause dealing with this matter, to the effect that the qualification of at least three of the Directors shall be in gas capital of the Company.

If mains for the distribution of electricity have not been laid by the Company in any rural parish in the limits of supply within three years, the Minister of Transport is to be empowered to revoke the powers of supply, if he thinks fit. In the case of gas supply, if mains are not laid within five years in any of the rural parishes or parts of parishes within the area of supply, any local authority, company, or person may apply for an Act of Parliament or Special Order for the purpose of providing the supply, and for the repeal of the Company's powers.

In the Bill as deposited, provision was made for the partial repeal of the powers of the Crowborough District Gas Company for the supply of gas and electricity, and of the Lewes Gas Company in respect of the supply of gas, in certain areas; but the provision for the repeal of powers of the latter Company has now been struck out. The area of supply of gas and electricity by the Uckfield Company has also been modified.

A clause has been inserted giving power to supply, but not manufacture, electrical fittings and appliances.

LEGAL INTELLIGENCE.

GAS MANAGER'S ACTION.

On Friday last Mr. George Helps, General Manager of the Nuneaton Gas Company, applied to Mr. Justice Lawrence, in the Chancery Division, for an Order directing the Oldham Corporation to give further and better particulars of their defence in an action which Mr. Helps is bringing against the Corporation—an action which relates to alleged secret processes in the manufacture and supply of gas. Mr. Trevor Watson, for the plaintiff, observed that his client's secret depended on the supply of gas of low calorific value. Defendants, however, stated that, having disclosed his system in specifications, Mr. Helps had no secret. The Corporation, independently of Mr. Helps, had been using gas of a diminishing calorific value for years. His Lordship held that the Corporation ought to state the calorific value of the gas supplied at the Higginshaw Works, and the occasions on which they had distributed gas of a lower calorific value than the plaintiff since the erection of the works. His Lordship also directed defendants to give particulars of certain interviews with Mr. Helps on which they relied.

GAS PLANT DISPUTE.

On May 6, in the Divisional Court, composed of the Lord Chief Justice and Justices Avory and Shearman, the case of *Newtownards Urban District Council* v. Messrs. *Perry & Co., Ltd.*, came up for argument.

Sir Malcolm Macnaghten, K.C., for Messrs. Perry & Co., said the matter came before the Court on a special case stated by an Umpire under section 19 of the Arbitration Act, 1889, for the opinion of the Court on a question of law in an arbitration between the Newtownards Urban District Council and Messrs. Perry & Co. Counsel said he would have to ask that the case might be remitted, on the ground that the Umpire had said things he ought not to have said, after hearing one side only, and had omitted to state facts which were essential for arriving at the conclusion of law which the Court was asked to advise on. There was a contract between the Council and the firm for the installation, by the latter, of a water gas plant. The Council made a claim against the contractors that the plant was not up to the contract. The matter was referred to arbitration; each party appointing an arbitrator, and the Umpire being appointed by the Court. Counsel then referred to the lengthy proceedings that took place in the arbitration, and said the case, in its present form, could not possibly stand.

Eventually it was agreed by consent that the case should be remitted to the Umpire with certain directions, to proceed with the case and make an award in the form of a special case.

GAS AND WATER DISPUTE AT LIVERPOOL.

An action brought by the Huyton and Roby Gas Company against the Liverpool Corporation to determine the responsibility for damage to a gas main and supply pipes, was resumed before Mr. Justice Finlay, at the Liverpool Assizes, on April 30. The Gas Company claimed that when the new Corporation water main was laid at Roby in 1923, the gas main and supply pipes lost their support and were pressed down by a heavy roller, causing an explosion and serious fractures to develop, together with considerable escape of gas. The Liverpool Corporation denied that they had caused the damage, and said they were not guilty of negligence. They further contended that the fractures were due to the old and defective condition of the gas pipes. A mass of expert evidence as to the formation of the two lines, the manner in which excavations had been made, and the reasons for the gas escaping, was tendered; and after legal argument, his Lordship deferred judgment.

IMPORTANT RATING TEST CASE.

COURT OF APPEAL.

(*Before Lords Justices* Bankes *and* Atkin, *and Mr. Justice* Lawrence.)

Metropolitan Water Board v. Assessment Committee of the Kingston Union and Another.

An important point in connection with rating assessments was raised in this appeal by the Assessment Committee of the Kingston Union from a judgment of a Divisional Court consisting of the Lord Chief Justice, Mr. Justice Avory, and Mr. Justice Acton. The Metropolitan Water Board have underground works in the parish of Teddington, and surface reservoirs in the parishes of Hampton Wick and Hampton. All these parishes are included in the Kingston Union area; and in arriving at assessments upon the undertakings mentioned for rating purposes, the Assessment Committee ascertained the capital value in each parish, and then applied a remunerative rate of interest.

The Water Board appealed to the Middlesex Quarter Sessions, contending that by this method they were over-assessed in regard to both the gross estimated rental and the rateable value, and that the method to apply should have been to assess the undertaking in each parish upon the usual principle of finding the rateable value of the whole from the receipts and expenditure, and then distributing it over the different parishes. The Assessment Committee objected that this method did not comply with the Parochial Assessments Act, 1836. The Middlesex Quarter Sessions upheld the Committee's contention, and stated a case for appeal.

The case stated showed that the gross receipts from the undertakings in 1920 were £3,105,649, and the working expenses £1,593,287, leaving net receipts £1,512,362. The differences between the Assessment Committee's figures and those of the Water Board were as follows:

—	Assessment Committee.	Water Board.
	£	£
Teddington—		
Gross rental	2,484	1,248
Rateable value	2,114	832
Hampton Wick—		
Gross rental	2,061	1,302
Rateable value	803	868
Hampton—		
Gross rental	85,446	52,220
Rateable value	67,862	34,220

The Divisional Court allowed the appeal, holding that the contractor's principle was not the principle to be observed, and that regard should be given to the revenue account and the receipts of the undertaking, and the restrictions placed upon it by statute. The present appeal by the Assessment Committee was from that decision. The case was a test one, and was said to have an important bearing upon similar undertakings throughout the country.

Mr. Mitchell Innes, K.C., Sir Malcolm Macnaghten, K.C., and Mr. Hedley (instructed by Mr. W. Taylor, Clerk to the Kingston Union), appeared for the Assessment Committee; and Mr. Tyldesley Jones, K.C., and the Hon. S. O. Henn Collins (instructed by Mr. C. A. Hunt) for the Water Board.

Delivering reserved judgments, the Court by a majority (Lord Justice Atkin dissenting), dismissed the appeal, thereby affirming the decision of the Divisional Court.

Towyn Gas-Works Project.—The Towyn Urban Council at a recent meeting discussed the desirability of purchasing the Towyn Gas-Works. It was resolved that the Aberdovey and Towyn Improvement Committees should consider the project, and report thereon.

Imperial Continental Gas Association Centenary.—A proprietor has given notice of his intention to move, at the ordinary general meeting of the Association to-day: "That a sum of £2000 be placed at the disposal of the Board to be utilized for the permanent endowment of such philanthropic object as they may select, having as its object the extension of assistance to deserving cases occurring among the families of employees of the Association; the said endowment to be an abiding memorial of the proprietors' gratitude to the Directors, past and present, for the valuable services rendered by them to the Association during the period 1824 to 1924."

MISCELLANEOUS NEWS.

GAS REGULATION ACT APPLICATIONS.

The following notices have appeared in the "London Gazette" regarding applications to the Board of Trade under the Gas Regulation Act.

Padiham Urban District Council.

The maximum price now authorized in respect of the supply of gas by the undertakers is 6s. per 1000 c.ft.; and the price they have asked the Board of Trade to substitute for this is 1s. 5d. per therm.

It is also proposed that an additional charge per therm of 2·25d. should be authorized in respect of gas supplied through a prepayment meter, with a further additional charge per therm of 0·4d. where the fittings supplied to be used with the prepayment meter include a cooking stove.

AMENDING ORDER.

Wakefield Gas Light Company.

The Board of Trade give notice that the Wakefield Corporation have made application under sub-section 3 of section 1 of the Act for an Amending Order revising the powers of charging authorized by the Wakefield Gas (Charges) Order, 1922, whereby it is desired that a standard price of 11·8d. per therm shall be prescribed.

SPECIAL ORDERS.

Brentwood Gas Company.

The Company are seeking a Special Order to enable them to use scheduled land for gas purposes, to raise additional capital, to establish co-partnership, and to make new provisions with regard to the supply of gas.

Tawe Valley Gas Company.

Application is to be made by the Company to the Board of Trade for an Order under section 10 of the Act to authorize them to raise additional capital, to make provisions as to dividend, to draft further regulations with regard to the supply of gas, and for other purposes.

Worthing Gas Light and Coke Company.

The Company are applying for an Order under section 10 to extend their limits of supply so as to include the parish of Findon, to authorize the Company and the Littlehampton Gas Company to enter into arrangements for the supply of gas in part of the parish of Ferring, and to enable the Company to raise additional capital, to issue capital for profit-sharing, to make regulations governing the supply of gas, &c.

DECLARATIONS OF CALORIFIC POWER.

Ellesmere Port and Whitby Urban District Council.—425 B.Th.U. (July 1.)

Heathfield and Waldron Gas Light and Coke Company, Ltd.—450 B.Th.U., in substitution for 490 B.Th.U. (Aug. 9.)

BELFAST GAS UNDERTAKING.

The policy of making citizens more interested in the greatest of their municipal undertakings is being successfully adopted by Mr. J. D. Smith, M.Inst.C.E., Engineer and Manager of the Belfast Gas-Works, on whose invitation members of the Belfast and District Chamber of Trade visited the undertaking last week.

The visitors, who were met by Mr. H. M'Laurin, J.P. (Vice-Chairman of the Gas Committee), and Messrs. H. M'Keag and G. Stewart, were conducted round the works by Mr. Smith and several members of his staff; and the whole process of manufacture and distribution was explained to them. The plant can produce approximately 14 million c.ft. of gas per day, and the daily output of one retort—about 55,000 c.ft.—is equal to the daily output of the whole works in their early days. The visitors also inspected the water gas plant, the meters, the generating station, the chemical works, and the purifying and cooling plants. After visiting the stove warehouse, the party assembled in the staff dining hall.

Mr. M'Laurin said that, since Mr. Smith took over the management of the works in 1910, the output of gas had been increased by 70 p.ct., and it was still increasing. During that period £576,000 had been spent on the improvement of the works, and a new holder had been erected at a cost of £156,000. If the Belfast public could see how the gas-works were conducted, they would recognize what a good manager was Mr. Smith. They wanted to make Belfast a smokeless city, and it would go a long way towards this if they could induce householders to use gas instead of coal fires.

Mr. J. M. Colton, President of the Chamber of Trade, in proposing a vote of thanks to Mr. Smith, said the Chamber were strongly in favour of economy and efficiency; and, so far as they could judge, there were economy and efficiency in the gas-works.

Mr. W. J. Pride, in seconding the motion, remarked that a great deal of the material represented by the bye-products was formerly imported into Belfast. The output of tar was as great as the amount used in the six counties, and one county took about half the quantity produced. He hoped other counties would use the tar produced at the chemical works they had just visited.

Mr. Smith, in reply, said he had been gratified by the interest the visitors had displayed. It was just fifty years since the Corporation had taken over the gas-works from the old Company; during that time the undertaking had handed over for the benefit of the ratepayers more than £500,000. They tried to run the works as economically as possible, and it was the wish of the management and the Committee that they should sell gas at the cheapest possible price.

EXAMINATION UNDER THE EDUCATION SCHEME OF THE INSTITUTION OF GAS ENGINEERS.

Forwarding copies of the questions set in the examination in Gas Supply on the 2nd inst., and in that of Gas Engineering last Saturday, Mr. Walter Hole, the Organizing Secretary to the Education Scheme of the Institution of Gas Engineers, points out that in the Higher Grade and the Diploma the paper has been divided into two sittings, each of three hours' duration, instead of, as previously, one paper of four hours. This has been done at the request of students themselves, many of whom last year found it impossible to complete the paper in the time then allotted.

The Examiners were, for Gas Engineering, Messrs. H. D. Madden, M.Inst.C.E. (Cardiff), W. J. Smith, B.Sc. (Bolton), and J. S. Thorman (London); and for Gas Supply, Messrs. S. B. Chandler (Tottenham), George Keillor (Greenock), Stephen Lacey, B.Sc. (London), and A. B. Roxburgh (Newcastle-on-Tyne).

GAS ENGINEERING.

Ordinary Grade (External Examination).

From 2 to 6 p.m.

Sketches can be adopted to obviate long and involved statements.
The general neatness of the paper, including that of the sketches, and also lucidity of expression, will be taken into consideration in assessing marks.

Eight questions only to be attempted.

1. Give a front and cross-section of a horizontal setting and furnace, indicating the passage of the gases.

2. Describe, with the addition of sketches, the principles of a typical method of mechanical retort charging and discharging. State the minimum time taken over the complete operation of charging and discharging. Give the weight of charge such mechanical charger would lay suitable for efficient carbonization, giving the length and size of the retort.

3. State what, in your opinion, is the best combustion chamber temperature, giving your reasons. What means are adopted to ascertain combustion temperature?

4. Give a description of the process of water gas manufacture. Describe, with sketches, the apparatus used.

5. Sketch and describe one type of atmospheric condenser. Give the size and area necessary for cooling one million c.ft. of coal gas per day, for an inlet temperature of 130° Fahr., to 70° Fahr., with atmospheric temperature 50° Fahr.

6. Describe a gas exhauster, and state how this is driven and controlled. State the effects of under-exhausting and also over-exhausting on both gas and tars, &c.

7. Describe plant for removal of tar and ammonia from the gas. State the desired temperature which you would expect to find at the inlet of such plant, and give your reasons. Describe what should be the arrangement and condensation to ensure that the whole of the ammoniacal liquor sold or delivered to the sulphate plant is not less than 10 oz. strength.

8. Describe the apparatus and method of testing the calorific value of coal gas. Show the calculations. What special precautions should be taken to ensure accuracy?

9. Describe the chemical and physical principles involved in (1) the regenerator furnace, (2) the setting. Give the chemical equations representing the reactions which take place.

10. Describe, by means of a sketch, the principles of a spiral-guided gasholder.

Higher Grade.

Part I., from 2 to 5 p.m.

(*Four questions only to be attempted.*)

1. Give the principal sources of gas coal, and indicate in what respects such coals differ. State their behaviour under carbonizing conditions.

2. Give the chemical composition of coal gas and water gas, and sketch and describe the apparatus, giving procedure for the complete analysis of both. Show how the calorific value of coal or water gas is arrived at from the chemical composition, giving an example.

3. State the general investigations and arrangements you would make when taking over the control of a horizontal carbonizing unit to obtain the most efficient results, both as regards therm and residual yields. Give the analyses of producer gas and waste gas which you would endeavour to obtain for maximum efficiency.

4. Describe what you consider are necessary conditions in the carburetted water gas plant to obtain efficient results, stating: (1) The steam and blast pressure; (2) the cycle worked and the reason for its adoption; and (3) the temperature of the carburettor under the varying quantities of oil. State with what regulating instruments you would expect a modern carburetted water gas plant to be equipped.

5. Show the chemical reactions that take place in the removal of sulphuretted hydrogen and the revivification of the purifying material. By what means can the activity of the purifying material be assisted? Describe a method for estimation of sulphur and tarry material in spent oxide.

Part II., from 6 to 9 p.m.

(*Four questions only to be attempted.*)

6. Describe a method for coke handling with which you are familiar, giving a sketch. What precautions would you take to ensure minimum wear and tear?

7. In construction of foundations, what weight per sq. ft. would you estimate that virgin soil would carry without sinking? (Clearly explain the type of virgin soil referred to.) What foundations would you put in for a load considerably exceeding that which the virgin soil or made-up ground would be capable of carrying without sinking? Explain the principles you would adopt, and give a sketch.

8. Describe, by the aid of sketches, the manufacturing process of sulphate of ammonia on modern lines. State how you would arrive at the efficiency of conversion of the ammoniacal liquor supplied into sulphate.

9. State where, in the process of manufacture, you would recommend the application of mechanical handling of materials in place of hand work; also the power recommended, with your reasons for same.

10. Describe, by the aid of a sketch, the type of grate suitable for burning small low-grade fuel in a works boiler. What precautions would you take to obtain the maximum efficiency? State what steam production you would expect to obtain per lb. of breeze under ¾ in. in size, containing 12 p.ct. moisture and 12 p.ct. ash.

Diploma.

Part I., from 2 to 5 p.m.

(*Four questions only to be attempted.*)

1. Review the effect of the varying percentage of oxygen in coal on the products of carbonization. Compare in this respect any two coals from different coalfields with which you are familiar.

2. Compare the effect of high and low steaming on the throughput and on the products of coal carbonized in a vertical retort system. Give an approximate analysis of the gas under each condition, stating the extent of steaming. Compare the behaviour and throughput of coal per retort in any well-known type of vertical retort installation, reciting two distinct coalfield types.

3. What do you consider the depth of fuel bed necessary in a horizontal retort house producer or generator for the production of good producer gas? Give analysis of such gas, and give and discuss the grate area you would recommend per ton of coal carbonized, sketching the type of grate referred to. Discuss the effect on the quantity and quality of the gas and residuals produced by a change of about 12 p.ct. variation in the temperature of a combustion chamber of a horizontal installation.

4. State briefly the causes of the existence of naphthalene in crude coal gas, and describe in detail a method for its complete removal from the gas—(*a*) giving the quantity of absorbent necessary, and (*b*) stating how this is disposed of when spent.

5. Discuss the application and merits (technically and commercially) of waste-heat recovery boilers to—(*a*) carburetted water gas plant, (*b*) vertical retort settings, and (*c*) horizontal regenerative settings. Show in each case the controlling influences and methods you would adopt for successful and economical operation, mentioning the quality and temperature of the waste gases you would expect available. State in lbs. the steam developed (from and at 212° Fahr.) per lb. of fuel used in the generator (indicating also the generator fuel consumption). Give your calculation, with the temperatures and CO_2 content of the waste gases at the various points in the setting, regenerator, waste-heat boilers, and the connections leading thereto, which you have assumed in your calculations.

Part II., from 6 to 9 p.m.

(*Four questions only to be attempted.*)

6. Sketch a cross-section of stills and saturator of a modern sulphate of ammonia plant. Explain the points to which you would give detailed attention to ensure satisfactory and efficient working, and give your reasons. Briefly describe, and give your reasons for, the necessary care and treatment of the waste gases and effluent liquor. What amount of sulphate of ammonia of 21 p.ct. nitrogen would you expect to obtain theoretically from 10,000 gallons of 10-oz. ammoniacal liquor? Show your calculations for this.

7. Assuming you are in charge of a works containing (say) the following plant, (*a*) one section of horizontal retorts, (*b*) one section of vertical retorts (steamed), and (*c*) one section of carburetted water gas or blue gas plant, discuss briefly the points you would watch, and describe what steps you would take when the three plants were in operation together, to ensure a proper mixture and to maintain the outlet gas at—(1) regular and constant calorific value, (2) regular and constant composition, and (3) regular and constant specific gravity. Explain why this constancy of values is essential.

8. State the prime movers you would employ, and the powers you would adopt, in the mechanical equipment of a medium-sized works, to reduce laborious work to a minimum, commencing with the handling of coal, and dealing with all operations throughout. Give your reasons, and state the efficiencies you would expect from each of the plants you would propose to instal.

9. Give a general résumé of, and illustrate by sketches, the methods adopted for foundational work in gas-works construction, mentioning the nature of the varying sub-soils which may be met, and the types of foundations which can employed on each. State how you would arrange foundations to carry on soft-yielding soils the following: (*a*) Heavy walls of horizontal retort houses, (*b*) concentrated loads as in the case of vertical retort settings.

10. Gas-works are bound to comply with certain Acts of Parliament in their methods of manufacture of gas and residual bye-products. Enumerate the leading points of the Gas Regulation Act, Alkali, and other Acts that operate and have to be observed in gas-works.

GAS SUPPLY.

Ordinary Grade (External Examination).

From 2 to 6 p.m.

Sketches can be adopted to obviate long and involved statements.
The general neatness of the paper, including that of the sketches, and also lucidity of expression, will be taken into consideration in assessing marks.

Six questions only to be attempted.

1. If gas reported escaping into telephone street boxes, state what immediate action you would take after arriving at the site, and how proceed to locate the leakage. Assuming the escape traced to a

broken main, describe the work of temporary and permanent repair—the latter with the aid of sketches.

2. A main 6 in. in diameter and 1000 yds. in length has been capped at either end, and the contained air raised to a pressure of 6 in. as measured by a water gauge; thereafter the pressure is observed to fall at the rate of one-tenth in 3 minutes. Calculate the rate of leakage in c.ft. per hour.

3. Make diagrammatic sketches of (*a*) a constant pressure governor, and (*b*) a constant volume governor for controlling gas flows up to (say) 30 c.ft. per hour. Show what forces maintain the governors in equilibrium when in action, and bring-out clearly points of similarity and difference in design. Which do you think is likely to be the more reliable in use, giving reasons?

4. State precisely how you would proceed to test a meter *in situ*, and how you would ascertain that it was of adequate capacity for its work. What are the faults that may develop in meters in use, and to what are they due?

5. Give the composition of a good blow-pipe solder for meter fixing. Also name a suitable flux, and describe its function. What tools is a fitter likely to require when fixing a 20-light meter in a private house?

6. Make sketches showing the construction of the burner, mixing chamber, and nozzle of a modern gas fire. Explain what provision is made for dealing with different pressures and gases, and describe the provisions made to ensure silent burning.

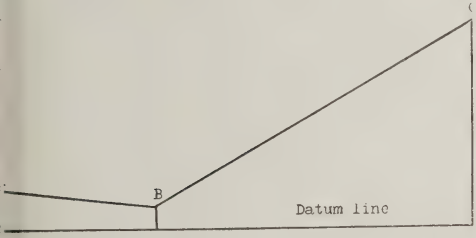
7. Describe, with the aid of sketches, the construction of a sealed type of geyser, and indicate the passage of the products of combustion and water respectively through the apparatus. To what would you pay particular attention when installing a geyser.

8. State how you would determine the thermal efficiency of a boiling burner in a cooker hotplate under working conditions. Give a calculation illustrating your answer. How have the higher efficiencies of modern hotplates been attained?

HIGHER GRADE.

Part I., from 2 to 5 p.m.

(Five questions only to be attempted.)



1. The diagram above represents a 12-in. pipe-line. The length of the pipe-line A, B, C = 1000 yards. The altitudes of A, B, and C are 100, 50, and 400 ft. respectively above datum. (*a*) If the specific gravity of gas = 0·6 and the gauge pressure at A = 3 in., what will be the pressure at B and C when no gas is flowing in the pipe? Sp. gr. of water as compared with air may be taken as 780. (*b*) When gauge pressures at A and C respectively are 3 in. and 2 in. and the sp. gr. of gas = 0·6, the rate of flow is found to be 27,000 c.ft. per hour. What will be the rate of flow when, other conditions remaining unchanged, (1) diameter of pipe = 6 in., (2) gauge pressure at C = 3 in., (3) sp. gr. of gas = 0·48?

2. Make a sketch of a mercury-sealed weight-loaded district governor. If the bell floating in the mercury seal is 24 in. in diameter, and the weight of the bell together with the valves and valve spindle suspended from it is 48 lbs., with what additional weight must the bell be loaded in order that the governor in action shall maintain an outlet pressure of 4 in. water gauge? If, with the governor in equilibrium, the outlet pressure falls one-tenth of an inch water gauge without affecting the inlet pressure, what will be the force tending to open the governor at that instant, and upon what factors will the time taken to re-establish equilibrium depend?

3. Discuss and compare the relative advantages of the various means that may be adopted for reinforcing the supply to districts where the pressure in the mains is tending to fall below the permissible limit during peak loads. In your answer have particular regard (*a*) to the necessity of providing for future increase in gas consumption, and (*b*) to the annual charges incurred in respect to capital and running costs.

4. What do you understand by the term "load factor" as applied to gas distribution problems? Show what bearing it has upon the economics of the industry with special reference to the developments of the last 20 years.

5. The following is an analysis of a mixture of coal and carburetted water gas:

	P.Ct. by Volume.
Carbon dioxide	2·6
Oxygen	0·8
Unsaturated hydrocarbons	2·4
Carbon monoxide	12·7
Hydrogen	46·6
Methane	25·0
Nitrogen	9·9

Give a brief account of the properties of each constituent from the standpoints of gas distribution and utilization. Name the constituents invariably found in town gas that are not included in the analysis, and state their significance in regard to corrosion of pipes.

6. To what do you attribute the great increase in the thermal efficiencies of gas engines in the last forty years? What do you consider should be the thermal efficiency and the mean pressure in the cylinder during the power stroke of a modern gas engine of 50 H.P.? Make a careful sketch of an indicator diagram of a power cycle from a modern gas engine, and show how such a diagram would be affected by (*a*) late ignition, and (*b*) early ignition.

Part II., from 6 to 9 p.m.

(Five questions only to be attempted.)

7. The mantles of a cluster burner in a street lamp are 15 ft. above the ground, and the following table gives the candle-power at various angles corresponding to the horizontal distance from the vertical axis of the lamp along the ground as shown in the first column.

Distance in Ft. from the Lamp.	C.P
0	200
5	280
10	320
20	310
30	280
40	270

Calculate the horizontal illumination at ground-level due to the single lamp at distances of 5 and 30 ft. from its vertical axis.

8. A hall of 60 ft. by 40 ft. by 15 ft. high is to be heated by hot-water radiators. The average temperature is to be maintained at 60° Fahr. (hall empty) with a temperature of air outside of 30° Fahr. Assuming (*a*) the average loss of heat through walls (including windows, &c.) = 15 B.Th.U. per sq.ft. per hour and loss through ceiling and floor can be neglected, (*b*) heat emitted from the radiator = 135 B.Th.U. per sq. ft., (*c*) air changed three times per hour, and (*d*) specific heat of air = 0·02 B.Th.U. per c.ft., calculate the radiator surface required. In what circumstances would gas heating of the circulating water be justified? Specify the type of gas apparatus you would recommend and the maximum rate of gas consumption (500 gas).

9. What precisely do you understand by "smothering" in a gas oven? To what various causes may it be due? Describe and compare methods adopted in two of the latest types of cooker to eliminate the possibility of smothering, while ensuring the highest practicable efficiency.

10. Discuss the relative merits of gas and coke for the provision of hot water for domestic purposes. Contrast the conditions specially favourable to each.

11. Write a complete specification for a pendant and lighting burner for prepayment supplies.

12. If you were asked to arrange for an examination of the consumers' supplies in a residential district, give a full account of the examination you would make with regard to (*a*) safety of installation, (*b*) adequacy of supply under all conditions, and (*c*) suitability and efficiency of appliances.

TESTING GAS METERS IN BIRMINGHAM.

Annual Report of the Official Inspector of Gas Meters.

In his report to the Birmingham City Justices' Gas-Meter Testing Committee for the year ended March 31 last, Mr. Frederick Colburn states that the number of meters tested totalled 126,770, as against 129,683 last year—being a decrease of 2913. The fees charged amounted to £7161—an increase of £28. The expenditure for the year amounted to £3172, showing a credit balance on fees of £3988, which has been carried to the Borough Fund.

Attached to the report are statistical tables giving an analysis of the results of the testings. Of the meters tested, 3774, or 2·97 p.ct., were rejected, as against 3·58 p.ct. last year. Of 9788 wet meters, 479, or 4·8 p.ct., were rejected; and of 116,982 dry meters tested 3295, or 2·8 p.ct., were incorrect. Of the 3774 meters rejected, 1665 were more than 2 p.ct. fast, 886 were more than 3 p.ct. slow, while 598 were rejected for unsoundness—227 external and 371 internal. Of 632 meters submitted for certification, 406, or 64·2 p.ct., were incorrect; 108 were more than 2 p.ct. fast, 25 were more than 3 p.ct. slow, and 59 passed gas without registering, while 91 were leaking internally or passing small quantities of gas without registering. Of the 45,644 new meters submitted, 25,152 were of the standard sizes, as against 17,244 last year. Repaired meters numbered 80,494, or 63·4 p.ct. of the total. The highest monthly percentage of rejections was 4·1, and the lowest 2·5.

During the year, four 10 c.ft. standard holders have been repaired and re-verified *in situ* by the Standards Department, London; the holders being re-stamped and certified as correct measures. The whole of the standards and auxiliary instruments have now been brought up to date.

Preference Stock Issue at Southend.—An issue, by Messrs. A. & W. Richards, of £50,000 of 5¼ p.ct. irredeemable preference stock in the Southend-on-Sea and District Gas Company, is advertised in to-day's issue of the "JOURNAL." The minimum price fixed for tenders is par; and offers must be sent to No. 37, Walbrook, E.C., by Thursday morning, May 21.

Gas at Becontree.—For some time now the "Westminster Gazette" have published articles on modern architecture and building efficiency. In the issue for May 5 was one dealing with the Becontree Estate of the London County Council. On the same page is an advertisement of the Gas Light and Coke Company, in which it is stated that of the 4754 houses at Becontree occupied to date, 4754 are lighted by gas by means of 8739 brackets and 22,425 pendants; 4754 are equipped with gas cookers; 2800 with gas water heaters; and 2270 with gas fires. At Becontree, as elsewhere, gas is proving its value.

CITY AND GUILDS OF LONDON INSTITUTE.

The following questions were set in the City and Guilds of London Institute Examinations in the subjects named.

GAS FITTING.

Chief Examiner: Mr. R. J. Rogers.

Grade II.—*Viva Voce.*

(All questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. With how many types of thermostats are you conversant? Are there any conditions under which you would not recommend a thermostat to be fitted to a hot-water apparatus? (*10.*)

2. Supposing that, owing to non-payment of gas account, you have orders to cut-off the supply of gas in a house, but that on calling you are unable to obtain access to the premises, what steps would you take to cut-off the supply, and what would be the procedure before the supply was re-connected? (*10.*)

3. What improvements have been made in modern gas fires to ensure silent burning? (*10.*)

4. Do you, or do you not, recommend a flue pipe to be fitted to the outlet of a gas-cooker oven? State your reasons for or against fitting a flue direct to the outlet of a cooker. (*10.*)

5. How would you test for soundness an installation of gas supply pipes—(*a*) if gas was available; (*b*) if no gas was available? (*10.*)

6. A gas service from main to meter has a defective stopcock inside the building, and you have to replace it with the gas on. How would you proceed to do this? State the precautions necessary. (*10.*)

Grade II.—*Written.*

(The maximum number of marks obtainable is affixed to each question.)

1. Give a sketch of a 6-in. water pressure gauge, and show a pressure equal to 3½ in. of water column registered upon it.

How many inches in water column are equal to 1 in. of mercury? (*50.*)

2. Describe the construction of a gas-steam radiator. Name each part, and explain exactly the steps that you would take in fixing the radiator in order to ensure its efficient working. (*50.*)

3. What are the advantages of a geyser fitted with a safety gas valve over a geyser fitted with interlocking gas and water taps?

Describe one type of safety gas valve fitted to a geyser (*50.*)

4. State the consumption of gas per hour of the following:

(*a*) The boiling burners and grill burner fitted on the hotplate of a modern gas cooker, size of hotplate 24 in. by 20 in.

(*b*) No. 2 size inverted burner.

(*c*) A six-tube double-loop gas-steam radiator—(i.) consumption on first lighting, (ii.) reduced consumption when automatic valve is in operation.

(*d*) An outside lamp fitted with nine No. 2 inverted burners under a superheater.

(*e*) An eleven radiant gas fire. (*40.*)

5. Name the various types of flue pipes fitted to gas appliances. Explain their composition, and state which type you prefer to use, and the reason for your choice. (*40.*)

6. Heat is given off by a gas fire in several ways; what are these? What percentage of each is obtained from a modern type of gas fire? (*40.*)

7. What are the essential features to be observed in fixing: (*a*) A 5-light dry prepayment meter; (*b*) a gas-heated wash boiler; (*c*) a nine radiant gas fire? (*50.*)

8. What is meant by the terms: (*a*) Diffused lighting; (*b*) concentrated lighting; (*c*) semi-indirect lighting; (*d*) indirect lighting?

Show, by sketches, how these various forms of lighting are obtained, and in what circumstances you would recommend their use. (*60.*)

9. State the general defects likely to occur in a 5-light dry prepayment meter after it has been working for a period and explain how they may be remedied. (*40.*)

Grade II.—*Practical Examination.*

1. Examine the geyser, and state to the Examiner the following:

(*a*) How the water travels from the inlet to the outlet pipe.

(*b*) How the products of combustion travel from the burner to the flue outlet.

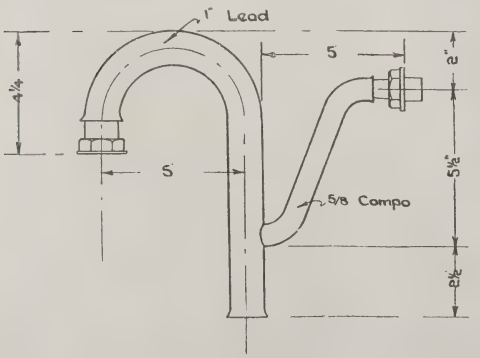


Fig. 1 (Grade II.).

(*c*) The consumption per hour.

(*d*) The size of gas and water supplies necessary to give good results. (*½ hour; 20 marks.*)

2. With the material provided make the lead and compo connection shown in fig. 1. The connection to be complete, with the joints as shown and to the dimensions given. (*1½ hours; 30 marks.*)

3. With the material provided make the control tap connection as shown in fig. 2 to the dimensions given. (*1½ hours; 30 marks.*)

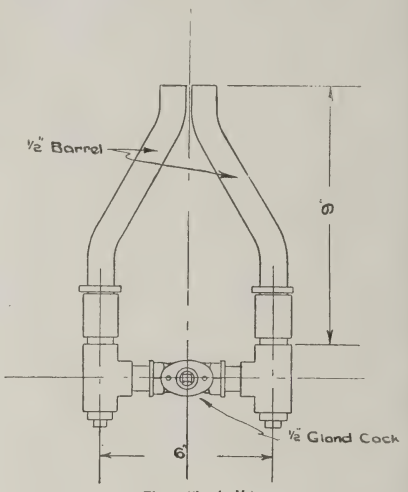

Fig. 2 (Grade II.).

4. Inspect the cooking stove, and explain to the Examiner the following:

(*a*) Consumption of gas per hour of the hotplate burners, also of the oven burners.

(*b*) What you consider should be a good oven temperature, and how long it is before this is obtained after lighting up the oven?

(*c*) The precautions that you would take when fixing the cooker, in order to ensure the maximum efficiency being obtained.

(*d*) Assuming that the oven burners were constantly going out after the oven door was closed, how you would deal with this defect. (*¼ hour; 25 marks.*)

5. Examine the prepayment dry meter and explain to the Examiner:

(*a*) Precisely how the gas passes from the inlet to the outlet.

(*b*) How the coin mechanism operates.

(*c*) What precautions you would take in fixing the meter.

(*d*) Points that would influence your decision in choosing a suitable position for this meter. (*½ hour; 25 marks.*)

6. Inspect the gas fire, and explain to the Examiner:

(*a*) The function of each part.

(*b*) The consumption per hour.

(*c*) The composition of the fuel.

(*d*) The precautions that you would take in fixing it. (*¼ hour; 20 marks.*)

Final Examination.—*Viva Voce.*

(All questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. A consumer complains of a generally bad supply of gas to his residence. How would you proceed to ascertain the cause of the complaint? (*10.*)

2. Describe the difference between an open type of geyser and a sealed type of geyser. (*10.*)

3. What in your opinion is the best way of dealing with the condensation tube of a geyser? (*10.*)

4. By what test would you ascertain whether the products of combustion from a gas fire were entering a room? If you found that they were, how would you overcome the difficulty? (*10.*)

5. In what way does a wet meter differ from a dry meter? What precautions are necessary when fixing both in (*a*) a warm position, (*b*) a damp position, (*c*) an exposed position? (*10.*)

6. Can a consumer compel a gas undertaking to give a supply of gas? If so, when and why is he able to do so? (*10.*)

Final Examination.—*Written Paper.*

(Not more than six questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. Describe, and show in plan and elevation, a domestic hot water installation suitable for supplying the apparatus shown in the plans on the examination paper.

Ground Floor.—Range boiler, gas heated circulator, and one sink.

First Floor.—One bath, one lavatory basin, and one towel rail.

State the size of boiler, gas circulator, and the consumption per hour, the capacity of the hot water storage tank or cylinder, and the size of the circulation pipes. (*60.*)

2. Give a description of the construction and use of the following: any type of thermostat, antifluctuator, gas leakage indicator, low-pressure service governor. (40.)

3. State briefly the principle upon which a gas engine works, and give (*a*) the consumption per hour when running on full load, (*b*) the size of service and meter that you would instal for a 50-B.P.H. engine, (*c*) common faults that arise from time to time with a gas engine, and how you would remedy such defects. (50.)

4. A consumer is building a house for his own occupation, and you are asked by him to give your reasons why he should use gas in preference to electricity and solid fuel. State fully what your reply would be, indicating the advantages of using gas for (*a*) lighting, (*b*) gas fires, (*c*) wash boiler, (*d*) cooker, (*e*) geyser, (*f*) circulator. (50.)

5. A consumer requires a supply of gas to a hardening furnace. It is necessary for the muffle to be supplied with low-pressure gas in conjunction with a supply of air from a compressor. State (*a*) what would be a suitable ratio in the respective volumes of air and gas, (*b*) the pressure in lbs. per sq.in. of air, (*c*) what, in your opinion, is the best means to adopt to prevent the air passing into the gas supply pipe. (50.)

6. A shop front, 14 ft. wide, is to be lighted by means of outside lamps; the lighting and extinguishing to be operated from inside the shop. State the number and size of lamps you would use, and the method that you would adopt for the lighting and extinguishing of the lamps, also the essential points that a gasfitter should bear in mind when fixing the lamps.

Assuming that the lamps to be used are of the preheated cluster type, state what, in your opinion, are the advantages, or otherwise, of this type. (40.)

7. A garage, 14 ft. long by 10 ft. wide by 9 ft. high, constructed at the side of a dwelling house, is to be heated by means of gas. What form of gas apparatus would you employ for this purpose? Show by means of a sketch where you would fix the apparatus, and state the consumption of gas necessary to maintain a temperature of 50° Fahr. with an outside temperature of 40° Fahr. (40.)

8. A consumer requires a geyser to be fitted capable of delivering 2 gallons of bath water per minute. State (*a*) the consumption of gas per hour for which you would allow, (*b*) the size of gas and water supply that you would instal, assuming the meter to be 50 ft. away, (*c*) the precautions that you would take to ensure the most satisfactory and efficient results.

No flue is available in the bathroom. Show by means of a sketch how you would run the flue pipe from the geyser. (50.)

9. What is meant by the term "thermal efficiency?" What is the thermal efficiency obtained by the use of gas in the following: (*a*) Ring burner on cooker hotplate, (*b*) a gas oven, (*c*) a gas-heated geyser, (*d*) a gas fire? (40.)

FINAL EXAMINATION.—*Practical Tests.*

(*Candidates must attempt all questions.*)

1. Examine the two gas-heated hot-water appliances, and explain to the Examiner for what purpose each is most suited. Further:

(*a*) Give the consumption per hour of each.

(*b*) Explain how each operates.

(*c*) Assuming each has been in use for some time, state precisely how you would overhaul it so as to ensure the most efficient results.

(*d*) Explain how the thermostat operates.

(¼ *hour; 20 marks.*)

2. With the material provided make the lead connection as shown in fig. 1 to the dimensions given; joints to be blow in. (1½ *hours; 30 marks.*)

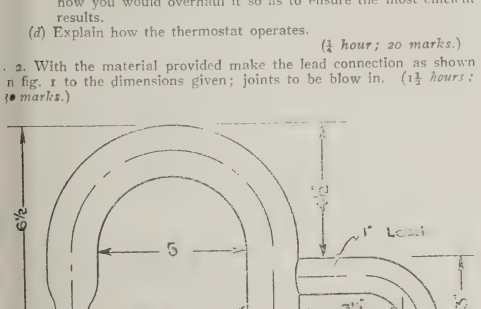

Fig. 1 (Final).

3. Examine the two appliances given you by the Examiner. State what these are, precisely how they act when in operation, and in what circumstances you would recommend them to be installed. Give fully your reasons. (¼ *hour; 20 marks.*)

4. With the 1-in. steam quality barrel make the steam radiator connection, complete with flanged joint, to the dimensions given in fig. 2. (1½ *hours; 30 marks.*)

5. Inspect the sketch plan fig. 3 on the plate attached to this paper, which shows an underground meter chamber ready to accommodate a 1000-light cylindrical meter. Explain to the Examiner (*a*) the method that you would adopt to lower the meter to the bed and the precaution that you would take to prevent possible damage, (*b*) step by step how you would fix the meter, (*c*) the size of service

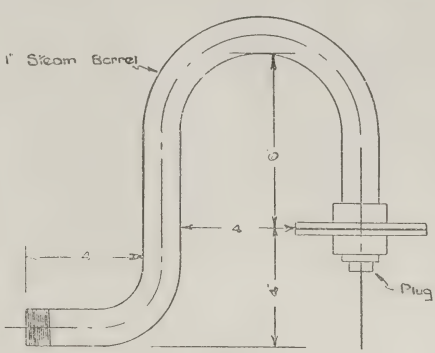

Fig. 2 (Final).

to the inlet, and the size of by-pass that you would fix. (¼ *hour; 25 marks.*)

6. With the material provided connect up the tinman's low-pressure soldering-iron stove; also connect up the pressure gauge. Explain to the Examiner (*a*) the consumption per hour of the stove, (*b*) the advantage of this type of stove over solid fuel, (*c*) read off the pressure on the gauge. (¾ *hour; 25 marks.*)

COAL-TAR DISTILLATION AND CRUDE INTERMEDIATE PRODUCTS.

Chief Examiner: Mr. W. H. COLEMAN.

FINAL EXAMINATION.—*Written.*

(*Not more than six questions to be attempted. The maximum number obtainable is the same for each question.*)

1. Describe, with sketches, what you consider to be the best arrangement of a modern intermittent tar still, with preheater and other necessary adjuncts.

2. Give some account of the manufacture, properties, and uses of *either* the hydrogenated *or* the chlorinated derivatives of naphthalene.

3. Describe, with sketches, the process and plant used in manufacturing pure benzole from crude naphtha or light oil.

4. Describe the manufacture of 60's carbolic acid. Define the term "60's carbolic acid" and describe the method of testing this acid.

5. Give a specification for creosote oil suitable for preserving timber, and describe the process of using it for this purpose.

6. How is pyridine suitable for denaturing alcohol made? Give an account of the properties and uses of pyridine.

7. Describe fully the manufacture of sulphate of ammonia from gas liquor; state for what purposes it is used; and describe the method of testing it.

8. State to what special hazards the workmen in tar works are exposed, and how they can be lessened.

FINAL EXAMINATION.—*Practical.*

(*All the questions may be attempted if time allows, but full marks can be obtained from* THREE *satisfactory answers. The maximum number of marks obtainable is the same for each question.*)

1. Examine the sample of pyridine marked A, and state your opinion of its quality.

2. Test the sample of motor benzole marked B, and state your opinion of its quality.

3. Determine the percentage of ammonia and of free acid in the sample of sulphate of ammonia marked C.

4. What is sample D? Examine it in the usual way, and state your opinion of its quality.

COKE AND BYE-PRODUCTS MANUFACTURE.

Examiner: Mr. C. P. FINN, B.Sc., F.I.C.

FINAL.

(*Not more than eight questions to be attempted. The maximum number of marks obtainable is affixed to each question.*)

1. Describe, with the aid of neat sketches, a modern type of coal washer to deal with rough slack of size 2 in. downward. (35.)

2. Discuss the composition and properties of the various types of refractory materials used in coke-oven construction, and indicate the suitability of each variety for any particular purpose. (40.)

3. If you were designing a new coking plant, what methods of quenching and handling coke would you prefer? Describe your scheme (using sketches), and give the reason for your choice. (40.)

4. Discuss the physical and chemical properties of coke, and their bearing on the iron industry. (35.)

5. Give your views (with suitable sketches) as to an installation to deal with the distillation of 400 tons of tar monthly. (35.)

6. Illustrating your answer by means of diagrams, describe any two of the following:

(*a*) A gas meter for combustion of coke-oven gas under boilers.

(*b*) A meter for the measurement of crude coke-oven gas.

(*c*) A pyrometer for the use of foremen and gas regulators.

(*d*) Some type of gas calorimeter. (40.)

7. Enumerate the principal points by attention to which you would secure a practical maximum of economy in the heating of a battery of coke ovens. (45.)

8. Give a detailed account of *one* of the following determinations:
(*a*) The efficiency of a benzole scrubbing plant.
(*b*) The value of a sample of sulphate of ammonia. (35.)
9. Set forth the considerations which would influence your choice of any particular type of ammonia recovery plant. (40.)
10. Write a short essay on any *one* of the following topics:
(*a*) Recent developments in coke-oven design.
(*b*) Suggested new processes of benzole recovery.
(*c*) Labour-saving devices on modern plants.
(*d*) Low-temperature carbonization. (45.)

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

There is no change to report in the situation, except the general cumulative effect of continued lack of trade. The market closed for the week under dull and depressing conditions, with a lamentable lack of general inquiry.

Gas coals continue idle and uninteresting, and new business is extremely scarce, with keen competition for any stray orders which come along. Second-class qualities are weaker, and, while the general nominal quotation remains at about 17s., business has been reported in some brands as low as 16s. Wear Specials and best qualities are nominally 19s. 6d., but most brands can be obtained at 19s. f.o.b., and possibly even less for prompt and convenient tonnage.

Other Durham unscreened sorts are in no better plight. The demand for coking is very poor, and best makes are only 17s. to 17s. 3d. Bunker orders are keenly competed for, and best makes are about 17s. 9d. to 18s.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

Gas coals in Yorkshire and Lancashire are quieter in demand for immediate delivery, and forward contracts have been fixed rather earlier this year. Prices generally are 2s. per ton below those of last year.

The recent cold weather has had a steadying effect on the demand for household fuel, and although some producers have reduced their prices slightly, others, in a more favourable position, are maintaining their winter figures.

The industrial outlook appears to have slightly improved, possibly owing to the fact that the irregular working of collieries will cause certain required descriptions of coal to become scarcer than they are at the moment. The commoner grades are still being offered at low figures; but these are not being taken advantage of to any great extent.

The shipping trade continues dull; but there is a hope that a better situation will obtain when producers are compelled to put their products on the market at prices which will compete with those of the nearer Continental coals.

Prices at Hull at the week-end were: South Yorks.—Hards, Association, 20s. to 21s.; screened gas coal, 18s. 9d.; washed trebles, 20s.; washed doubles, 17s. 6d. to 18s. 1½d.; washed singles, 16s. 9d.; washed smalls, 12s. 6d. to 12s. 9d.; unwashed doubles, 16s. 6d.; rough slack, 10s. 9d. to 12s. 6d.; smithy peas, 19s. 3d. to 20s. 6d. West Yorks.—Hartleys, 17s. to 18s.; screened gas coal, 18s.; washed trebles, 18s. 6d.; washed doubles, 16s. 6d. to 17s.; washed singles, 16s. 6d.; washed smalls, 11s.; unwashed trebles, 17s. to 17s. 6d.; unwashed doubles, 13s. to 13s. 6d.; rough slack, 10s. 6d.; coking smalls, 9s. Derbyshire and Notts.—Top hards, 19s. 3d. to 21s.; washed trebles, 17s. 6d.; washed doubles, 17s.; washed singles, 16s. to 16s. 6d.; washed smalls, 12s.; unwashed doubles, 14s. to 15s.; rough slack, 10s. 6d. to 11s. Yorks., Derbyshire, and Notts.—Screened steam coal, 15s. to 17s.; gas coke, 21s. 6d. to 24s.; furnace coke, 16s. 6d. per ton.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

While in its broader aspects the market could hardly be worse, some of the collieries manage to find a fairly steady outlet for their production without curtailing the working week by more than a day or so. This can only be said, however, of those undertakings which, from their geographical position, have the first pull on the markets, and are not greatly susceptible to the competition of districts where supply has outrun absorptive capacity. At the best pits of Cannock Chase and the Warwickshire coalfield a fair amount of regularity is maintained. Elsewhere in the Midlands, collieries which have special economic advantages are making a fair turnover; but more generally the industry is in a sore plight. Prices are very unstable, the unbalanced production of different grades of fuel, owing to the inconstancy of demand, being a very difficult problem. Spot lots are forced on to the market in increasing bulk and numbers. There is no alternative in many cases but to accept the best prices that can be got, so that the position is becoming more demoralized.

Weather conditions have given a slight stimulus to the call for the best grades of house coal. In some cases there is a delay of two or three weeks in getting delivery, but these are quite exceptional and of purely local significance. Steams and other industrial coals are plentiful and cheap. D.S. nuts and beans are in very ample supply. There is again a glut of slacks, and spot lots are offered at lower rates.

Coke is weak, without quotable change. Two North Lincolnshire blast-furnaces are being re-started for the service of the Scottish tube and plate trade; but the new pig iron production will involve displacements elsewhere, as there is no expansion of consumptive requirements.

CURRENT SALES OF GAS PRODUCTS

The London Market for Tar, Tar Products, and Sulphate.

London, *May* 11.

The market for pitch remains unaltered, the price continuing nominal at 41s. to 42s. per ton at makers' works.

Considerable quantities of tar are being delivered for road work.

Creosote is quiet, and the price is unchanged at about 7d. per gallon net and naked at makers' works.

Solvent naphtha, 95/160, is firm at about 1s. 8d. per gallon.

Pure benzole and pure toluole are unaltered at about 1s. 10d. per gallon.

Tar Products in the Provinces.

May 11.

The average values for gas-works products during last week were: Gas-works coal-tar, 27s. 9d. to 32s. 9d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8¼d.; crude, 65 p.ct., at 120° C., 11d. to 1s. 1d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 7½d. to 1s. 8¼d. Toluole, naked, North, 1s. 6¾d. to 1s. 7¼d., nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 6d. to 6¼d.; salty, 5⅝d. to 6¼d.; Scotland, 5⅝d. to 6d. Heavy oils, in bulk, North, 6¼d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

[We regret that the quotation for salty creosote was given last week as 5⅝d. to 6¼d. This should have been 5⅝d. to 6¼d.]

Manchester District Tar Prices.

The average prices realized for the sale of tar, according to the sliding scale, for the months of February and March, were £2 12s. 7·46d. and £2 9s. 3·19d. respectively.

TRADE NOTES.

The Anglo-Galvanizing Company, Ltd.

This firm have published a booklet giving details in reference to their process of cold galvanizing (the Bianco process). It is stated that the coating of zinc is perfectly smooth, homogeneous, and compact, and the resistance to corrosion is higher than the coating by the hot method.

Safe Working of Air Compressors.

The notes on this subject compiled in a booklet recently issued by the "Monitor" Patent Safety Devices, of Wallsend-on-Tyne, will prove of value to those in charge of air compressors. Any reader of the "Journal" who is in charge of power plant may have a free copy of this booklet on application to the firm.

Messrs. Clayton, Son, & Co., Ltd.

This firm have received an order from the Windsor Royal Gaslight Company for one of their cascade tar dehydration plants having a capacity of 10 tons per day. A similar plant was recently dispatched to the order of the Municipality of Singapore Gas Department, and another cascade plant has just been put into operation for the Borough of Peebles Gas Department.

CONTRACTS OPEN.

Coal.

The Skipton Urban District Council are inviting tenders for the supply of 10,000 tons of gas coal. [See advert. on p. 486.]

The Gas Committee of the Corporation of Workington are inviting tenders for the supply of 9000 tons of gas coal. [See advert. on p. 487.]

Tenders are invited by the Melton Regis Urban District Council for the supply of 2500 tons of unscreened best gas coal. [See advert. on p. 486.]

The Gas Committee of the Ashbourne Urban District Council are inviting tenders for the supply of 4000 tons, or part thereof, of best screened gas coal and washed gas nuts. [See advert. on p. 487.]

Tar.

The Directors of the Littlehampton Gas Company are inviting tenders for the purchase of their surplus crude coal tar for the year ending June 30, 1926. [See advert. on p. 486.]

EXTENSIONS.

Extensions at Blackburn.

The Blackburn Corporation Gas Committee have received formal sanction from the Ministry of Health to borrow £60,000 for the provision of a gasholder and renewal of oil gas plant. The Corporation will receive a grant in aid from the Unemployment Grants Committee.

Ramsey Gas Company and Electrical Powers.—A lengthy discussion took place at a recent special meeting of the Ramsey (Isle of Man) Town Commissioners with regard to a proposal by them to promote a municipal scheme for the supply of electricity, and to oppose the application of the Ramsey Gas Company to obtain powers to do so. A number of business men in the town presented a petition urging the Commissioners not to proceed with the municipal scheme, on the ground that it was of a speculative character. However, by seven votes to five the Commissioners adopted a resolution that they should oppose the Gas Company's application for powers to instal an electric supply, and should proceed with their own scheme.

Explosion at Belper Gas-Works.—When a purifier was being opened at the Belper Gas-Works, which belong to the Derby Gas Light and Coke Company, an explosion occurred which resulted in slight injury to seven men.

Garforth Collieries, Ltd.—We are informed that the Registered Office of the Garforth Collieries, Ltd., has been transferred to the Offices of the Old Silkstone Collieries, Ltd., Dodworth, near Barnsley. The secretaryship has been taken over by Mr. S. P. Harrison.

Dukinfield Gas Balance-Sheet.—The balance-sheet of the Borough of Dukinfield Gas Department for the year ended March 31 states that the sale of gas amounted to nearly 96 million c.ft., which was an increase on the previous year of 5¾ millions. There was a gross profit on the year's working of £4071, and a net loss of £300. The average price of gas, however, was 3s. 6·52d. per 1000 c.ft., as compared with 4s. 1·33d. for the preceding twelve months.

New Issues Over-Subscribed.—The Tottenham District Light, Heat, and Power Company's recent issue of 5¾ p.ct. preference stock was largely over-subscribed. No tender below £102 5s. p.ct. was successful, and the average price of the tenders accepted was £102 6s. 10d. p.ct. The issue of £8000 of 6¼ p.ct. irredeemable preference stock of the Wells Gas Light Company was also considerably over-subscribed; the prices ranging from £105 per £100 stock to par.

Hyde Exhibition.—The Hyde Gas Company are to be congratulated upon the organization of a very excellent exhibition, which has just concluded at the Town Hall, Hyde. Opened on May 4 by Mr. G. F. Drinkwater (the Chairman of the Company), the exhibition continued to attract large crowds for the whole of the five days during which it was open. The cookery lectures and demonstrations held each afternoon and evening created considerable interest, and were well attended. The very comprehensive display of gas apparatus on show was supplied by Messrs. W. H. Dean & Son, Ltd., Messrs. Fletcher, Russell, & Co., Ltd., General Gas Appliances, Ltd., the Richmond Gas Stove and Meter Company, Ltd., and Messrs. John Wright & Co.

Manchester Gas Department.—The financial statement of the Manchester Corporation Gas Department for the past year, with the estimates for the current year, were approved at a meeting held on May 1. It was announced that, notwithstanding the extraordinary increase in the sale of gas during the previous year, demand was still well maintained, and a further increase had been realized. The output for the twelve months was 7,218,369 c.ft., against 7,136,192 c.ft. last year. The income for the year amounted to £1,400,647, against an expenditure of £1,253,694. After the deduction of £90,457 on account of interest on loans, there remained a net profit on the year's working of £56,496, which had been applied to the sinking fund for the redemption of loan debt. The estimated profit on the current year's trading was put at £42,961.

Guest, Keen, and Piggotts.—A Company, with a capital of £40,000, has been registered to adopt an agreement between Guest, Keen, & Nettlefolds, Ltd., and Thomas Piggott & Co., Ltd., and to carry on the business of manufacturers of mains, pipes, conduits, &c., and vessels of all kinds for conveying, transmitting, storing, measuring, and otherwise utilizing water, gas, oil, and electricity, manufacturers and drawers of tubes and pipes, &c.

Manchester Meter Testing.—Mr. A. Winterbottom (Official Inspector of Gas Meters for the City of Manchester) has submitted to the Justices of the Peace his annual report for the year ended March 31. The number of meters tested during the year amounted to 60,673, showing an increase of 8146 as compared with the previous year. The fees charged totalled £3345. The number of meters tested is the highest on record. The expenditure amounted to £2711, showing a credit balance of £705. Of the meters tested, 2455 were rejected, or 4·04 p.ct. Of the total wet meters tested—viz., 4886—309, or 6·3 p.ct., were rejected; and of 55,787 dry meters tested, 2146, or 3·8 p.ct., were rejected. The number of prepayment meters tested during the year was 35,014. Standard meters numbered 10,929; the remaining 14,730 being meters of the ordinary type.

Good Gas Sales at Accrington.—Addressing the Accrington District Gas Board, on April 30, the Chairman (Alderman D. C. Dewhurst) said it was too early to forecast the financial results of the year, but gas sales were booming. The production had increased by 27 million c.ft. over last year (an increase of more than 40 p.ct. since 1919). This did not look as though they were "flogging a dead horse" in gas, as someone declared a little time ago. They had fixed 1600 gas cookers, fires, and boilers during the year; and this work was still going on. Gas was being used more than ever in industry and in domestic life. They were working hard to improve the distributing system, and many miles of new pipes had been laid. They had taken from slot meters £45,428, or 101 tons of copper. They had added nearly 400 consumers to their books.

Returns for the Chorley gas undertaking show that during the last municipal year 3,277,000 c.ft. more gas were consumed than in the previous year. In March alone there was an increased consumption of 624,000 c.ft.

Summer courses arranged for students of the Bradford Municipal Technical College include lecture courses and laboratory classes in gas analysis, analysis of coal and coke, and demonstrations in boiler-house practice, with special attention to elimination of the smoke nuisance.

The Buxton Town Council have considered a letter from the Ministry of Agriculture and Fisheries, together with a report from Mr. J. Race, giving the results of his analysis of the various liquids which enter the River Wye from the gas-works. The Gas Engineer was instructed to carry out the suggestions made by Mr. Race to stop the pollution of the river.

CARBON DI-OXIDE RECORDED BY ACTUAL MEASUREMENT.

THE "S.A.W." CO_2 RECORDER

(SIMMANCE, ABADY, & WOOD'S PATENT)

makes a definite volumetric analysis of a gas sample drawn from a continuously moving stream. ERRORS due to gravity, osmotic pressure, humidity, &c., are consequently avoided. ACCURATE readings are obtained under all conditions of pressure or draught as there is no empirical scale.

STOCK MARKET REPORT.

ALTHOUGH markets did not respond to the extent expected to the reduction in income-tax, stockbrokers report that business shows a steady improvement. The restoration of the gold standard, involving a general overhaul of investments by large holders, was partly responsible for the activity; but in addition there was a distinct increase in the number of inquiries for all classes of shares.

No material changes occurred in gilt-edged stocks, and Railways continued dull. There were some interesting features, however, in the Industrial market. Courtaulds, after the previous week's fiasco, were actually sold down to 92s. 6d., rising later to 94s. 6d.

It will be seen by the record below that there was an increase in the number of transactions recorded in the Gas Market. Holders of South Metropolitan stock are to be congratulated on the result of the Company's application to Parliament. It is reported that the Select Committee of the House decided last week that the basic rate of 11d. per therm —*i.e.*, the price at which gas can be sold to authorize a minimum dividend of 5 p.c. to be paid—is justified at present, subject to a revision in ten years' time. This freedom from interference for such a long period will be of great value to the Company. The ordinary stock of the Company now stands at 93-95, there being a fall of 1 point on the week; but the depreciation has not been so heavy as on the stock of the other Metropolitan Companies. Excepting Liverpool 5 p.ct. ordinary, which rose 2 points to 89-90, all the changes during the week on the ordinary stocks were again on the downward side.

The following transactions were recorded during the week:

On Monday, Bournemouth 5 p.ct. 12¾. Brentford "A" 95, Commercial 4 p.ct. 87, Continental Union 35¼, 7 p.ct. preference 88, Gas Light and Coke 84¼, 84⅜, 84¼, 84⅜, 85, 85⅛, 3½ p.ct. maximum 63¾, 64, 64⅜, 4 p.ct. preference 79, 3 p.ct. debenture 60½, Hong-kong and China 17, Imperial Continental 180⅝, Montevideo 66, Primitiva 10s. 3d., 10s. 6d., South Metropolitan 93¼, 93⅜, 94, 94¼. Supplementary prices, Aldershot 5 p.ct. "A" 81½, Dover 5¼ p.ct. debenture 102⅜.

On Tuesday, Alliance and Dublin 66, Brentford "B" 95, Croydon sliding-scale 100, Gas Light and Coke 83½, 83⅜, 84, 84⅛, 84⅜, 3½ p.ct. maximum 64, 4 p.ct. preference 79, 79½, Hastings and St. Leonards 3½ p.ct. 75, Hornsey 137½, 138, Imperial Continental 181½, 182, 3½ p.ct. debenture 73, 73½, Lea Bridge 99⅝, 100, Liverpool 7 p.ct. preference 105, Portsea Island "C" 97, Primitiva 9s. 9d., 10s., 4 p.ct. debenture (1911) 63⅜, South Metropolitan 93⅜, ¾ p.ct. debenture 61½, Southampton 84, 84½, Tottenham "B" 98, 98½, 99. Supplementary prices, Brighton and Hove 4 p.ct. debenture 70, Portsea Island 4 p.ct. debenture 73.

On Wednesday, Aldershot 4 p.ct. preference 71, 71½, Alliance and Dublin 66⅜, 67⅛, Brentford "A" 95, "B" 95, 6 p.ct. Richmond debenture 104, 104½, 104⅜, Commercial 4 p.ct. 86½, Croydon sliding-scale 100½, Gas Light and Coke 83⅜, 84¼, 84⅜, 84½, 3½ p.ct. maximum 64, 4 p.ct. preference 79, Imperial Continental 182, Liverpool 7 p.ct. preference 104½, Montevideo 65, Primitiva 9s. 6d., 9s. 9d., 10s., 10s. 3d., 4 p.ct. debenture (1911) 64¼, South Metropolitan 93, 93⅛, 94¼, South Suburban 5 p.ct. 97½, Southampton 84½, Tottenham "B" 97. Supplementary prices, Danish 80s., 82s. 6d., 83s. 1¾d., 5 p.ct. preference 5½, Malta and Mediterranean 1st 7 p.ct. preference 5⅝, North Middlesex 4 p.ct. debenture 79½.

On Thursday, Bombay 5 *ex* div., Brentford "A" 95, "B" 95, 5 p.ct. preference 96, British 111, Commercial 4 p.ct. 86¼, 3½ p.ct. 86¼, 3 p.ct. debenture 58, European 7, Gas Light and Coke 83½, 83⅜, 84, 84½, 84¼, 84½, 4 p.ct. preference 79½, Imperial Continental 181, Montevideo 65½, Oriental 105 *ex* div., Primitiva 9s. 9d., San Paulo 5 p.ct. debentures 43¾, South Metropolitan 93½, 93⅜, 94, 94¼, Swansea 7 p.ct. preference 102½, 103. Supplementary prices, Brighton and Hove 7 p.ct. debenture (1930) 106, Danish 80s. 7½d., 5 p.ct. preference 5⅝, Malta and Mediterranean 1st (7 p.ct. preference) 5¾, 2nd (7½ p.ct. preference) 5½, Southend-on-Sea 5 p.ct. new "B" 88, 88½, Tottenham 7½ p.ct. mortgages, 1931-5, 105, York Town and Blackwater 7 p.ct. add. ordinary 10½.

On Friday, Alliance and Dublin 66⅛, Bombay 5 1/16 *ex* div., Brentford "A" 95, 95¼, Continental Union 7 p.ct. preference 91, Gas Light and Coke 83½, 83⅜, 84, 84½, 3½ p.ct. maximum 63⅜, 4 p.ct. preference 79, Maidstone 5 p.ct. 125, 125⅜, Primitiva 9s. 7½d., South Metropolitan 93½, 93⅜, 94, 6½ p.ct. debenture 103½, Tottenham "A" 117, Wandsworth 3 p.ct. debenture 59. Supplementary prices, Malta and Mediterranean 2nd (7½ p.ct. preference) 5½, 5¾, Tottenham 5½ p.ct. preference 104½.

There was a shortage of money in Lombard Street last week on account of the payment of the final instalment of about £11,000,000 on the 3½ p.ct. Conversion Loan, and borrowers had to pay as much as 5¼ p.ct. for fresh overnight money, although 4½ to 4⅜ p.ct. was the usual rate. Treasury Bills consequently commanded a higher average rate—£4 10s. 6·29d.

The Foreign Exchange Market was quiet, but generally rates moved against this country. Sterling rate closed at 4.84⅜, French francs at 92.07½, Belgian francs at 96.02½, and Italian lire at 118.10.

Silver was quiet at 31½d. per oz., and gold was unchanged at 84s. 11½d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

'OL. CLXX., No. 3236.] WEDNESDAY, MAY 20, 1925. [77TH YEAR.

EDITORIAL NOTES.

The Gas Exhibit.

IPHASIS may be placed on "The" in the above title, be-ıse the Exhibit is—good as was that of last year—the ;t thing of the kind that has been done. A visit to embley at the end of last week satisfied us on that score. .d we came away strongly impressed with the fact that is the most imposing feature in the Palace of Industry, :ause of the attractiveness, from the popular point of :w, that met our gaze and scrutiny at every turn. was one of the glorious sunlit days that were ex-rienced last week, when the world was full of life, and ople were taking a keen interest in what was going on out them—interest quickened by light and brightness. nshine adds greatly to the glories of Wembley, and is a tent excitant to the desire to share fully in the interest d pleasure offered there with such lavish hand. And y by day last week more people journeyed to Wembley an on the corresponding days of last year immediately ceeding the opening. All concerned in obtaining, and ıging for, a full measure of success in its mission to the ·itish Empire Exhibition are devoutly trusting that Old ıl will comply with the wishes of the people, and not be niggardly as he was last year in ministering to their ppiness.

Those who have devised and brought to the point of mpletion the Gas Exhibit know well how much bright-ss and life contribute to the attraction of the public. And ightness and life are there in just those proportions ıich bring into relief the vast extent of utility which the dustry offers to the world and his wife. The General ıd Executive Committees are mightily pleased with the ·couraging reception the results of their efforts have ought to them during these early days. But that, we ope, is only the beginning of a veritable wave. The Com-ittee were well advised to annex the extra space which as available this year adjoining last year's habitation. 'e see several advantages in this, especially on the days hen the crowd is largest. The additional space gives more rculating room, and so better opportunities for inspec-on. It has enabled the Committee to breathe more freely, take a larger view of things, and to make the Exhibit ore comprehensive than last year. Its features were de-·ribed in our special Wembley number, and the various ·ticles showed the breadth of the demonstrated interest -interest which embraces our most important Dominions, ıd our domestic and industrial life at home.

The object of the Exhibit is to serve the interests of ıe gas industry, irrespective of supply undertaking or ·anufacturing concern. The modern way of doing these ıings is by following the "all-in" policy—that is to say, resent our capabilities to the largest possible extent in manner which will be of benefit to the whole gas industry, ıd that way is the right one. In propaganda work of this ind the first thing to be done is to impress upon the ublic the facts as to what gas can do; and this is not be accomplished by a mass collection of different makers' ppliances. The respective advantages of different types ın best be told, illustrated, or proved through other chan-'els. The conversion of the public is the first matter to be taken in hand. It is fundamental to all else; and as that conversion proceeds, we can go ahead. That aspect is again exemplified in the Exhibit this year. So is another. In respect of domestic applications, our womenfolk, who dominate the arrangements in our homes, regard our offers and demonstrations from two aspects—the artistic and the utilitarian. Only last Friday at Wembley we heard one lady say that the exhibit must, and does, dispel all doubts which exist in the minds of some ladies that gas applications cannot be clothed in the artistic merit which will conform with the requirements of the modern home. Those gas engineers and managers whose minds have not developed beyond the "C" incandescent burner of the 'eighties, and the large ugly "Universal" inverted burner of the early part of this century, had better note that the modern home requires gas fittings and heating and cooking appliances of compatible design—design divested of the repulsive ugliness of past times. What is available in this respect should be patronized by all gas men, who should be the first to use every effort and every opportunity to blot out the past, and to secure greater stability by being very much up-to-date. Picturesqueness is a feature of the Gas Exhibit—refinement and beauty on lines which comply with modern taste and requirement, and arrest the attention; and they serve to bring out the vast range of utility which gas applications offer in the home—not only in this country, but in the Dominions. In the demonstration at the Exhibit, one is also struck by the considerable influence which British practice in gas application has had upon the better-class homes in the Dominions. From it all projects the vast range of utility in gas application, in both the domestic and industrial regions.

It is indeed a fine display, and much more spacious in every respect than last year. We talk, for example, in general terms of smoke abatement, of the health-giving power of the sun's rays, and of the beneficial effects of the latter being so largely diminished by the smoke-screen provided by domestic hearth and industrial chimney. The Exhibit shows how the gifts of science and increased knowledge can be utilized for the preservation of the gifts of Nature. The utilization is a responsibility, with profit attached. That has to be impressed on the communities served by the gas undertakings of the country, as well as the fact that, by utilizing fuel in a scientific manner, those who do so are serving themselves by reducing the use of those things that create labour and so deprive them of leisure, which it is easy enough to secure when unnecessary work is the cause of its attenuation or absence. Gas engineers and gas salesmen will be personally inspecting the Exhibit, and learning of the work that is going on in the demonstration and cooking hall. There are for them object-lessons in the art of propaganda. But it is the public whose attendance is desired in constant stream. The provision is there for their education; their attendance alone will make for ultimate success. Because of this, every gas undertaking should supplement the general advertising, and make known throughout their supply areas that the Exhibit is a feature of Wembley that should not be missed. Co-operative effort in securing visitors is the way to maximum success.

While writing on the Exhibit, may we particularly invite the attention of kindly disposed readers who visit the Ex-

hibit to the display of the beautiful pottery made by disabled soldiers at the Ashtead Pottery? The work is illustrated by a gas-fired oven. Sir Lawrence Weaver, who is interested in this effort to enable these men to earn their own livelihood, asks for inspection and patronage. It is a good cause, which all may confidently support and commend.

The Coke Competition.

We wish strongly to impress upon those who are working at papers for one or more of the three sections in the Coke Competition that delivery must be made, by post, to the Editor of the "Journal" not later than the 30th of June. But in order to assist those to whom the task of adjudication has been confided, it would be a convenience, and contribute to an early decision, if papers to which the finishing touches have been given are sent in before that date. We would reiterate the point that, while prizes to the amount of £1000 are offered (through the generosity of the Woodall-Duckham Companies, though they are taking no part whatever in the examination of the papers or in making the awards), the honour of being among the winners will in itself be a prize of no mean value.

Never was there a time when a competition of the kind—a pooling of information, results of experimental work or practical experience, and suggestion—was more necessary in the interests of the first and the largest revenue-producing secondary product of the industry. The condition of the coke market to-day is sufficient evidence as to the truth of this. We have to ascertain what is best to be done to improve demand, so as to restore, maintain, and even enhance the position that coke has occupied in respect of the contribution it makes to the reduction of the net cost of our primary commodity. Many minds have been occupied as to the best methods for selling coke. The question is one of larger dimensions than that. We have to get back to the very genesis of the coke, and to a proper understanding of the requirements of users, or would-be users if convinced on the point of utility and satisfied that they could constantly get what they want. The deeper we go into the matter, the more we learn of the widely diverse characteristics of coke in different places—the divergencies being such that the poor qualities in some districts do infinite harm by creating a false reputation for coke generally—the contradictory experience creating the view of unreliability. That is a pity; and the view can only be corrected of it by those whose coke cannot boast of good properties ascertaining whether, on balance, it would not pay them better to investigate the means of improving the quality. There are large fields for coke for steam-raising and other industrial use, and for domestic purposes; but the fields have to be cultivated. The demonstration of good results will alone accomplish this; and the most efficient results are only achievable by the quality of the coke being right and the conditions of its use correct. Quality of coke is a matter in which a good many well-known factors participate; and one has to consider how far those factors can be economically applied in practice. The handling of coke and its grading according to purpose are also important, and should be stressed here (though in a separate section in the competition) in company with the qualitative aspect. There are many gas-works producing and preparing coke for the market which give excellent results; and there are works which go on week after week and year after year turning-out inferior material, and attempting to dispose of it without any effort at preparing it to suitable size for the purposes to which it has to be applied. We should not in these various connections overlook the fact that the gas industry is in a position to take a large part in the solution of the problem of coal conservation through putting it (as it does) to the most profitable use from the national point of view, and by assisting in bringing about a better co-ordination of the utilization of fuel. But our credentials in respect of quality, suitability, and dependability of coke must be right if we are to realize and maintain our proper status in this matter of great national moment.

Deliberately, and from long observation, we say that this question of coke as a commodity and a contributor of no mean importance to the revenue of our industry has been permitted to drift all too long. It must not be allowed to become (perhaps to-day we ought to say continue to be) a drug in the markets. We should, if wisdom prevails, seriously concentrate on what is best to be done to make it more popular, and not sit still simply waiting for something to turn up. We know of the active influences that are at work in opposition to the utilization of tar for road purposes, and of the influential competition that there is in this respect. We know, too, that sulphate of ammonia is exposed to severe competition from increasingly powerful new sources. Thus there are many reasons why no effort should be spared to produce (within economic limits) coke which shall become so popular that the normal condition will be clear coke yards, despite greater quantities of coal being carbonized to meet the expanding utilization of gas. To this end, we sincerely hope the Coke Competition will contribute. As particulars of this are still being sought, it may be again mentioned that full information as to the sections, conditions to be observed, and the prizes to be won was given in the "Journal" for Feb. 18.

Municipal Authorities and Section 1.

The annual report of the Scottish District of the National Gas Council, which was published in the "Journal" last week (pp. 464-5), contained a reference to the position of the municipal authorities of Scotland in relation to section 1 of the Gas Regulation Act. It is a subject which has been made interesting owing to the idea which some administrators of municipal gas undertakings entertain that the therm basis would have effects of a somewhat different order (though gas consumers in one place are much the same in type and habits, and in their gas applications as those in another place) in municipal areas than in company areas. They do not appear to have heard that, in municipal gas supply areas where the system has been applied, the troubles which they apprehend have failed to materialize. A good proportion of the municipal authorities owning gas-works in Scotland—including Edinburgh and Glasgow—do not agree with their doubting English compeers; and we know that the municipal administrators of Scotland, with their native caution, do not accept innovation until they have examined it all round, and have turned it inside out. The Scottish District of the National Gas Council two years ago strongly advised municipal authorities to take early steps to apply the Gas Regulation Act. One result is that to-day 33 of the gas-possessing municipalities in Scotland are satisfactorily working on the therm system—the public have favourably received it; and there is not the slightest desire to revert to the old order of things. If Scotland, why not England? If some English municipalities, why not the remainder? We see nothing to differentiate between them; neither do the Board of Trade, as was plainly revealed when the deputation from English municipalities had early in the year, their interview on the subject with Mr P. W. L. Ashley, C.B., the Principal Assistant Secretary of the Industries and Manufactures Department, and Mr H. C. Honey, the Director of Gas Administration. It was perfectly obvious to the deputation that the Board have resolved to carry out the intentions of the Legislature in passing the Gas Regulation Act, though they would rather voluntary application be made than have to use the compulsory power conferred upon them by the Act.

In Scotland, however, there are some extremely small gas undertakings carried on by local authorities; and those who are prominent in the affairs of the Scottish District of the National Gas Council, and who have themselves voluntarily come under the Act, see good reason why such concerns without any real staff, carbonizing a small tonnage of coal a year, with few customers and low total consumptions, should be exempt from change. Some of them are not in a position to carry out tests of any description; and to leave them as they are (unless their supplies could with economy, and therefore public advantage, be taken over by a larger neighbouring concern) would not make the slightest difference to what might be regarded as the universal application of the therm system to statutory undertakings—when that desirable condition is consummated. A small deputation from Scotland—Mr James Campbell, of Dunfermline, the President of the

orth British Association of Gas Managers, and Mr. W. Napier, of Alloa, accompanied by Mr. E. J. Fottrell, the National Gas Council—have interviewed Mr. Ashley d Mr. Honey on the subject; and these gentlemen ap- ar to have been impressed by the evidence laid before em by these advocates for the exemption of the small ncerns. Neither Mr. Campbell nor Mr. Napier can be cused of desiring personal relief, for they are both work- g on the therm system (respectively with declared values 430 and 440 B.Th.U.), and are strong believers in its ing applied wherever practicable. No definite promise as made as to the exemption of small undertakings; but e matter is to receive consideration. From what is said the report, it may be that Mr. Ashley and Mr. Honey ay determine to recommend that works with an output of million cubic feet and below should not be compelled to me under the Act. In other words, that it should be thin the discretion of those responsible for such works nether or not they do so. No possible harm would be ne by that. But the final decision of the Board has to announced.

Miners Show the Way.

HE labour world appears to be in topsy-turvy state just ow; and it is difficult to presage what will happen. it from the jumble of current conditions, it is possible r the searcher after light on the position to find indica- ons which show a satisfactory movement. It is found at those labour leaders possessing magnitude of mind alize that the depression in our industries is largely due economic conditions being against them, compared ith other countries, and that the latter are getting work hich we want, but which we are unsuccessful in obtain- g owing to our circumstances, which include the con- quent burden of a mass of unemployment. A few onths ago there were many imposing claims made for gher wages by important trade unions in the country; id men, intemperate in language and prognostication, enaced the country with a year of unprecedented labour heaval and trouble in the attempt to extract extra gold om places where it does not exist, and where it is im- ssible to make more while an economic return in work not given for the money expended in wages. Unem- oyment on the grand scale continues; and these men o not show, or care, how there can be any permanent medy of the condition. The only way to remedy it is, course, to create work—not artificially, or for tem- orary purpose, for that would only mean, without other dical alterations, a return, when that work ended, to the *atus quo ante*. The creation of work must be by bringing urselves into a position competitive with other countries, id that can only be done by the co-operation of all con- rned.

As we have said, the gravity of the position is being alized by the more thoughtful and balanced minds in the bour world; and one result of this is that there have en joint conferences in different industries on the situa- on, and investigation of conditions. Probably owing to is, less is heard to-day of upheavals and doing those ings which would only bring about a more gloomy world r British labour. It is no use fighting for anything hen the issue will be to worsen the pre-existing state; id that is what is being recognized by intellects that ave not taken flight beyond the bounds of sanity. he lessened trade that is being done, and the reduction the activities of our ordinary manufacturing industries, ave made three points clear—that the amount of employ- ent must be consonant with requirement; that in order to store employment, in the affected industries, output ust cost less; and that if wages are not to be lowered, en there must be more output for the money paid. That ay, and that alone, is the route to increasing the capacity industry to pay more money, consistent with a balance tween work and pay being maintained which will enable dustry to meet competition.

The miners, engineering trades, the railwaymen, gas orkers, and others have been seeking higher pay. So ar as the gas workers are concerned, the conditions of ie industry in respect of revenue from secondary pro- icts have seriously altered; and so they have in the rail- ay world in respect of reduced traffic, owing to the state of the coal and manufacturing industries. The engineering trades are in a sad plight due to the inability to retain and obtain work in this country through the much cheaper rate at which it can be done abroad. It is a singular thing that the mining industry, poor in its circumstances to-day in consequence of the trend of adverse events (to which there has been material contribution through the autocratic and disastrous policy of the Miners' Federation), is the one which to-day is giving evidence of the effect which good work for fair pay can have upon the fortunes of previously non-paying pits. The evidence is not to the liking of the Miners' Federation and of the constituent unions; and it shows that among the rank-and-file there are intelligences at work which are leading the men to exercise their own will rather than be under the bondage of union rule, and sacrifice themselves, their dependents, and their homes. We hope this sort of thing will grow, and ultimately result in the unions conforming their policy to the conditions of the times, instead of pursuing a course which is detrimental to the interests of the members of their organizations. There has been reference in our columns on former occasions to what is being done at the Vauxhall Colliery, near Wrexham. The pit was losing money week by week, and the owners had determined to close down (as several other collieries have had to do) owing to reduced trade and inability to compete at profitable prices. Someone wisely suggested an experiment in co-operation. The threatened closing-down of the colliery had cast gloom over the neighbouring village. The men determined to give co-operation a trial, despite the appeals of an alarmed Union to have nothing to do with such an obviously prudent course; and then came the menace of suspension from the Union, upon which, however, there has not been action. A guarantee fund was started to protect the men from loss; and the whole village is happy to-day. The experiment has been going on for some weeks. About 75 p.ct. of the men are, by their own efforts, earning more than the minimum wage laid down by the national agreement; and this is solely due to a decision to give a new interpretation to the seven-hour enactment. Hitherto the accepted interpretation has been seven hours from bank to bank; but this was modified in the Vauxhall Colliery so as to substitute for the bottom of the shaft district timing stations situated about 300 yards from the seams—thus the wages paid for unproductive walking time has been transferred to the account of productive labour. The result of the longer time at the face is an increase of output from 16 to 20 p.ct.; and the hewers are earning about 10s. per ton of extra coal won. The other costs are unaltered; and the difference in the cost of production is such that the sale of the coal shows a margin of profit, instead of a loss. While this continues, there will be no fear of the men being thrown out of employment. So long as there was no chance of the colliery being run without loss, their outlook gave no hope of employment, with so many unemployed in the industry.

Those miners are pioneers in proving that past policy has been wrong—that miners have it within their power to improve the economic conditions within the industry which gives them employment, just as they have it within their power to do those things which make it impossible for large parts of the industry to be carried on. The old policy has promoted insecurity; the Vauxhall policy security and happiness. The example is having good effect. The Bedwas Collieries were about to close down; and the 2500 men affected made the proposal that they should retain their employment by increasing the output! The miners at the Houghton Colliery (Durham) have made it possible to keep it open by agreeing to work an hour longer each day. At the Birchenwood Colliery, North Staffordshire, the firemen accepted the owners' proposal that there should be co-operative working; but at a mass meeting, the miners, ill-advised by their leaders, rejected the proposal. The incident shows that co-operation is the last thing desired by the men's leaders. The Newbiggin Colliery in Northumberland had reached a stage at which the owners could not continue its operation, but the miners, rather than lose their work, have accepted a reduction in pay of 3d. per ton. The Unions do not like the accruing testimony to the pernicious effects of their unsound policy. Union leaders who adhere to and defend a policy which

inflicts injury upon an industry, and converts profitable into unprofitable production, are traitors to the interests of the members they are elected to serve. The present conditions show there are other ways than increasing wages and shortening hours by which the interests of members can be protected. The Vauxhall men have shown one way—through the simple expedient of putting in approximately seven hours at the face, and so enlarging the production per shift—and it has automatically brought them additional pay. These events are the handwriting on the wall; in them there is warning for all trade union leaders. They would do well to give heed to them, before the rank-and-file take matters into their own hands, and pursue the course which their own intelligence and conscience assure them is the right one. Greater sense has been shown at the Vauxhall and other collieries than has emanated for a long time past from the Miners' Federation. Compare it with the silly ravings and threats of Mr. Cook! The Vauxhall men have retained their employment and increased their income by rational and peaceful methods; Mr. Cook would ruin employment and pay in the industry by militant tactics.

The Government and Electricity Development.

It seems that we are getting close now to the revelation of the contents of the report of Lord Weir's Committee, who have been considering the question of electrical development on the national scale. The Prime Minister, speaking last Friday at the Oxford University Conservative Association, stated that the report has been completed; its recommendations are being most carefully examined by the Cabinet; and if, in the result, they endorse the Committee's policy, its carrying out will be the first important task the House of Commons will have to face on reassembling in the autumn. From another source, it is learned that the recommendations have already been under the consideration of the Minister of Transport (Lieut.-Col. Wilfrid Ashley); and a Memorandum has been circulated among the members of the Cabinet. With what degree of actual knowledge the same Parliamentary authority gives the information, we do not know, but he asserts that Ministers regard the proposals which have emanated from the Committee as providing the basis for an excellent scheme, and that the main object of the Bill which is being framed is to make provision for linking-up generating stations, and co-ordinating and standardizing their power service.

Reverting to the speech of the Prime Minister. He appears to be obsessed by the idea of "cheap power." There are other things which are more important to industry, and which would help it far more if they were "cheapened," or lowered in their pecuniary weight. It is quite true that we consume less units of electrical energy than other countries, which, the Prime Minister asserts, are inferior to our own in industrial production. The latter is not a recommendation to an acceptance of their example in the consumption of more units of electrical power. Notwithstanding, the Prime Minister considers that, unless something is done, and done quickly, the discrepancy between this country and others in respect of electrical power consumption will increase by leaps and bounds, year by year, until we are unable to compete. The Prime Minister should come down to earth from the heights to which he is soaring in this matter, and inquire what are the actual power costs per unit of production in this country compared with others dependent (as we are) upon solid fuel for the generation of electricity. He should also make research into the question of the proportion that power costs have in the total costs of manufacture per unit of output. We think he would be astonished at the smallness. The exercise might cause him to conclude that it is not the expense of power but other items in the total costs of production which really matter, and which are the brakes upon the industrial progress of this country. Incidentally, he might further find that heat is no less important to industry than power. We shall be interested in learning precisely the lines of the report and recommendations of Lord Weir's Committee. Some indication may be given tomorrow, as, on the estimates of the Ministry of Transport being introduced for discussion, the Liberal Party are proposing to raise the question of the development of electricity supply; and the Government may use the opportunity for an announcement as to their proposals.

The King and Queen.

The King and Queen were highly interested during the tour of the Gas Exhibit last week. His Majesty recalled t fact that last year one of the attractions was the "Seven Ag of Woman," and that there were children in the nursery scen Their Majesties were also interested in the tar exhibit (not f away) of the National Gas Council. No one should miss th People are talking of the delightful conception of the scene the sign of "The Jolly Jack Tar." Members of highw authorities and road surveyors are being invited to visit t exhibit, and to obtain information from the expert in charg A little local influence might be added to the official invitation

Good Attendance Record.

The total number of visitors to the British Empire E hibition this year up to, and including, last Saturday w 348,192. The total number of visitors in the week, excludir the opening day, was 227,475. Last year's figures for the fi six days, which included the Cup Final day, totalled on 301,555. It is therefore evident that the attendance this ye has, so far, greatly increased over last year, during the simil period. The total number of visitors on Saturday was 99,252

A Colliery for Sale.

It is not often that in our editorial columns we special draw attention to advertisements. The idea of gas unde takings becoming colliery owners is not a new one. It h frequently been discussed by municipal authorities owning ga works; but the suggestion has never matured. Among o "For Sale" advertisements to-day is one offering the Re heugh Colliery for sale. This is situated at Gateshead-on-Tyn It is estimated that unworked coal is available there for fif to sixty years; and the present owners consider that it wou be a paying proposition for acquisition by gas-works, coke a bye-product manufacturers, engineers, &c. Those who ha thought it would be a good thing for their gas-works to own colliery will perhaps be inclined to probe further this defini suggestion, and ascertain whether there is real economy in for gas-making purposes. There has been no time within th past decade when, we imagine, collieries could be purchased a lower figure than to-day.

Coal Industry Inquiry.

If no definite result issues from the joint inquiry into th economic position of the coal industry by the Mining Associ tion and the Miners' Federation, the facts revealed by th investigation must have some good influence in reducing th chasm between the owners and the miners. A statemer which has been issued as to the proceedings shows that th course of procedure resolved upon was that the facts relatin to the present position of the industry should first be examine that the question of causes should next be considered, and th remedies should then be discussed. Among the first facts di cussed was the reduction of the export trade—from 74 millio tons in 1913 to 62 millions in 1924, and at the rate of 52 mi lions per annum in the first three months of this year. Th average f.o.b. price at the port of shipment was 23s. 4d.; an this has been reduced to 20s. 9d., which figure in preser circumstances means a loss of about 1s. 6d. on every ton e ported. The wages cost in Germany is about 50 p.ct. of t total costs, as against 70 p.ct. in this country. While earning and labour costs are less in Germany than here, the othe items of expenditure are higher. The miners' representative point out that the cost of living in Germany is not so great a in this country. Reference is also made to the great increas in the production of brown coal in Germany—124 million ton in 1924, compared with 87 million tons in 1913—which enter into competition with German black coal, and thus intensifie the competition with British coal. Bearing also upon compet tion is the fact of the increased output capacity. For instance the sales policy of the Westphalian Syndicate is now base on an output capacity nearly 70 p.ct. in excess of that of 1913.

British Costs and Effects.

A comparison is given of working costs in 1913-14 com pared with May to December, 1924. In the former period, th total costs per ton of commercially disposable coal wer 9s. 5½d., of which wages accounted for 6s. 10½d. In the latte period the costs were 18s. 11·74d., of which wages accounte

13s. 6·7d. The earnings per shift were 6s. 5·64d. in 1913-14, compared with 10s. 10·32d. in May-December, 1924. The put of coal per shift in the respective periods was 20·23 cwt. 17·8 cwt. Thus while the earnings have gone up 67·9 p.ct., output has been reduced by 12·1 p.ct. Figures were pre-ted which show that in the period from May to December year, 111 pits were closed, involving 59,000 men. On y 7, the Secretary of Mines stated that 256 coal mines, mally employing 55,300 wage earners, have been closed ce Nov. 1, 1924, and have not been re-opened. During the ne period, 90 mines, employing 10,000 wage earners, have n opened or re-opened. The total number of persons unem-yed in the industry in March was 148,358, or 11·8 p.ct. of total employed. Transport and freight charges have also n considered. Other points have yet to be cleared up, and n the question of causes and possible remedies will be icked. Meantime, an illustration of one good remedy (re-red to in an editorial article in this issue) is being supplied co-operative working, in which the men are doing a better t. The average increase in earnings and the reduced output shift mentioned above, which combine adversely to affect costs per ton, are highly important factors.

ıde Facilities Act.

Further guarantees under the Trade Facilities Act have n given by the Treasury, bringing the aggregate at March to £55,577,811. Among the new items is £26,000 to the ot District Gas and Electricity Company, Ltd., and ,000,000 to Synthetic Ammonia and Nitrates, Ltd. The ıarantee to the latter is to cover the extension of the plant.

ting of Machinery.

The Central Executive Board of the National Gas Council e had under consideration the Rating and Valuation Bill; l a Special Rating Committee of the Council are closely tching it. The fact that the rating of machinery has been rievance among manufacturers for a long period was alluded in a speech by Mr. Neville Chamberlain in the House of mmons last Wednesday. He reminded members that a De-tmental Committee, which studied the question in 1923, nd that in the application of the law there was a serious k of uniformity between unions, which ought, if possible, to remedied. Concluding that manufacturers were entitled to ne relief, they recommended that loose tools and plant and chines operated by hand or foot should be excluded from ing, and that the rest of the machinery should be divided o two classes. One class was to be considered as part of the reditament and be fully rated. This was to include motive ver, lighting, heating, and ventilating apparatus, lifts, eleva-s, rails, and tramway tracks and plant or combinations of nt and machinery of the nature of the structure. The ond class was process machinery, which was also to be ed, but was to receive a rebate of 25 p.ct. of the amount of rate. The Committee also made proposals as to the setting of a panel of referees who might decide whether any par-ılar piece of machinery fell into one or other of the two sses. The Bill follows the recommendations of the Com-ttee. Mr. Chamberlain does not think it possible, however, put into the Bill a complete schedule of machinery to be ly rated; and he has adopted the expedient of setting up a mmittee whose duty will be to compile a list. This will be ised at intervals; and there is provision in the Bill for ections to be made and heard. The Committee rejected oposals of this kind on the ground that they were impractic-e; but Mr. Chamberlain does not see why this should be

He is also unable to accept the Committee's suggestion ıt certain machinery should be subject to 25 p.ct. rebate. e expense and protracted delay that would be involved in uing all this machinery, from which only 75 p.ct. would be ained for the rates, does not seem to him to be a business position. He feels that putting a charge upon a manu-turer because he is bringing his machinery up to date and tting himself in a position to compete more effectively with foreign competitors, is a thing which ought not to be couraged. The relief which the exemption of machinery l bring to the manufacturers will help them to increase ir output, and to employ more men; and therefore it will rease the general charge upon the ratepayers.

PERSONAL.

The Stockton Corporation have congratulated their Gas Engineer, Mr. W. W. Atley, on his appointment as President of the North of England Gas Managers' Association, and have given permission for the Association to be invited to hold their October meeting in Stockton.

Mr. T. J. Ashley, who for about twenty years has occupied the position of Chief Engineer to Messrs. Aldridge & Ranken, and as such has been known to a large number of gas engineers both in this country and abroad, has retired owing to ill-health, and will reside at Broadstairs. Mr. R. W. Green, on behalf of the Directors and staff, presented Mr. Ashley with a club arm-chair, in recognition of his unvarying kindness to the staff. Mr. Ashley, who has been a Director of the Company since its formation, will retain his seat on the Board; and Mr. Green, who has been with the Company for over seventeen years, has been appointed Chief Engineer.

Mr. J. W. Walker has been appointed Chief Salesman to Messrs. J. & G. Wells, Ltd., and his address is now Eckington Collieries, near Sheffield. His son, Mr. J. W. Walker, Jun., will succeed him as the Company's Agent for London, the Southern and Eastern Counties, Birmingham, and Midland Districts; and his address is "Ashleigh," No. 255, Grove Lane, Handsworth, Birmingham.

OBITUARY.

E. J. BROCKWAY.

We regret to announce the death of Mr. E. J. Brockway, J.P., Engineer, Manager, and Secretary of the Cleethorpes Gas Company, who, on May 11, passed away at his residence, Sussex House, Cleethorpes, in his 65th year.

Mr. Brockway, who was a native of Salisbury, began his connection with the gas industry at the works of Messrs. Willey & Co., Exeter. After completing his apprenticeship, he became an assistant to a gas engineer who owned or leased several gas-works. Here Mr. Brockway gained a good deal of experience in management and constructional work on a small scale. After four years as Assistant Engineer at Malton, he went to the Oakham Gas-Works as Engineer and Manager, and in 1890 left Oakham to go to Cleethorpes.

Some idea of the outstanding progress of the town and district of Cleethorpes, and incidentally of the Company who have served it so well in the matter of gas supply, is furnished by the fact that when Mr. Brockway first took up his duties in 1890 at Cleethorpes, the annual output of gas was about 20 million c.ft., while to-day it is just over 300 million c.ft. This has necessitated the laying of a considerable mileage of mains and services per annum, as well as rapid and extensive works reconstructions and additions. With increases over the previous year's output amounting at times to as much as 50 p.ct., it required considerable skill and foresight, not to mention courage, in order to avoid committing the Company to expedients which in the long run often prove disproportionately costly. That the late Manager achieved remarkable and lasting success in meeting these extraordinary conditions is evidenced by the present exceedingly prosperous state of the Company, and by the fact that they have consistently paid maximum dividends for the past 27 years.

In 1896 Mr. Brockway was elected President of the Eastern Counties Gas Managers' Association, and later served as District Member of Council of the Institution of Gas Engineers. As is well known, he was one of the pioneers in carbonization by means of vertical retorts. His experiments on a practical scale began with the Settle-Padfield process, from which he, in conjunction with Messrs. Robert Dempster & Sons, Ltd., of Elland, evolved a very successful form of intermittent retort which is still in operation at the Cleethorpes Works. Later he adopted the Dempster-Toogood continuous system, which is now working in conjunction with the intermittents—the combination making a very flexible and efficient production unit. Various other interesting experiments in plant and methods which have been initiated by Mr. Brockway and tried at Cleethorpes have been recorded from time to time in these columns, and the industry is the loser by the passing of such a devoted servant and able propagandist.

Mr. Brockway was, at the time of his death, a Director of the Woodhall Spa Gas and Water Company, which is also a very flourishing concern. He was formerly the sole proprietor of the Kirton Gas-Works, near Boston, Lincs., and Consulting Engineer to the Skegness Gas Company and the Bolsover Gas Company. As a County Magistrate and former Chairman of the Cleethorpes Urban District Council, he was highly regarded for the worth of his public services. Up to the time of his death he was Chairman of the Official Advertising Committee of the town, and did much to enhance the reputation of Cleethorpes as a health and pleasure resort. In the masonic world he secured high honours, and was one of the founders and past masters of the Lord Worsley Lodge, Cleethorpes. He was also a keen motorist and a founder of the Lincolnshire Automobile Club.

ELECTRICITY SUPPLY MEMORANDA

A correspondent in the provinces calls attention to some comments by "Meteor" in the "Electrical Times" for May 7, under the heading of "Burn More Gas and Coke;" and, in his letter, referring to the nature and form of those comments, he makes a remark which we will not repeat lest it hurts the feelings of our contemporary. Perhaps our correspondent does not know of the capacity of "Meteor" for utilizing in his writings the foam of sarcasm and generalities, instead of dealing with solid and material facts. The subjects of his sarcasm and platitudes on this occasion are statements made at the Chester District Conference of the British Commercial Gas Association regarding the relative economic merits of gas and electricity for various domestic and industrial purposes. Not in any part of his thin criticism does he advance a single point which negatives, by definite data, the statements made at that conference. If he will put forward such data, there will be both pleasure and profit in dealing with them. We will only touch on one point. He remarks: "Where gas meets electricity in a fair field, on anything like equal terms, electricity wins every time, and these frantic gas advocates know it." Does he mean "for heating, cooking, lighting, power, and every other conceivable purpose"? If so, then let us have, instead of the nonsense in the paragraphs before us, the evidence based on the "equal terms" for each of those purposes. Meantime, in his spare moments, "Meteor" might consider why it is that there are millions of gas cookers and gas fires in use in this country. Why is it that they have been increasing during immediate past years at a rate per annum without precedent? Why is it that, if electricity wins every time, the new heating connections made by gas in any locality far exceed those made by electricity? Why is it that one London Gas Company alone supplies more heat energy than the whole of the electricity supply undertakings in the country? "Meteor" should endeavour not to expose himself to ridicule when he opens the floodgates of his exiguous satire.

Sarcasm to Avoid Facts.

"Economy" of Electric Cooking.

The electrical people are not a little perturbed regarding the fact that experience by consumers with electric cookers is not aiding them in increasing the rate of output. After the first splash, demand declines; and the gas industry involuntarily increases its store of knowledge as to the dissatisfaction of users over their experiences, particularly in the matter of costs. To complaints of exorbitant expense for service rendered, the electrical people reply that it is all nonsense, and consumers are making a great mistake. But all the finesse they can bring to bear will not convince the users of the cookers that they must not trust the evidence of their own senses and payments. It is a considerable drawback to the electric cooker, apart from the expensiveness of electrical B.Th.U., that the experienced user of a gas-cooker has become accustomed to its flexibility and the large range of application of the hotplate, which, when attempted on the electric hotplate, results in an ugly shock. The electrician endeavours to console the user by telling him or her that it is only a question of refinement—a delicate care in the employment of the cooker—and all will be well. Now it is very easy to test the thermal and money cost of performing a given operation by the rival cookers, by doing the same work under the same conditions in both. If one ascertains from the meters the input of gas and electricity (the calorific power of the former is stated on every gas account rendered on the therm basis), then one knows the amount of heat expended usefully and in waste without going into all sorts of complexity to ascertain how and where the thermal energy goes. That is simple and truthful; so simple and truthful that we have been both amused and amazed at the essay of Mr. E. G. Ross, Assoc.M.Inst.E.E., in a recent issue of the "Electrical Review," to show that the idea of uneconomy even on the electric hotplate is due to misconception, and that by calculation it can be found that there is an actual money saving compared with the gas-cooker.

The Inception of the Argument.

Mr. Ross shows wonderfully profound thought, and an excellent capacity for arithmetical gymnastics, so that a plain method of making a test and calculation is displaced by something absolutely complex. We should like his article to be submitted to a layman, and see what he can make of the assumptions, crude testings, and gradually mounting-up totals for gas and subtractions for electricity, which are intended to show that electric cooking is at least 15 p.ct. cheaper overall than gas cooking—"other conditions being equal." Let us see how our critic arrives at this. He prefaces his singularly constructed statement with the remark that the advantage of electricity over gas for cooking in point of price is due entirely to the economic conditions attendant upon its use; and it is not true to say that it is intrinsically cheaper than gas for the purpose. We suppose that the "intrinsically" intends to convey that the heat energy of the gas is cheaper than that of electricity, but in its application it beco dearer. But the argument which follows, if it is intende prove anything, is (in our opinion) directed to showing electric cooking is "intrinsically cheaper" than gas cook Mr. Ross assumes that for a given article to be coo 1000 B.Th.U. are necessary over one hour, and that the ciency of the cooker is 100 p.ct. The gas required is there 0·01 therm. As there are 3420 B.Th.U. in 1 kw.-h., equivalent electrical energy required is 0·293 kw.-h. He ta as a "reasonable" price for gas 10d. per therm, and ¾d. kw.-h. for electricity. How many places supply current heating at ¾d. per kw.-h.? However, on his own figures, respective costs are 0·1d. for gas and 0·22d. for electricity. course, there are no gas or electric boiling rings which have efficiency of 100 p.ct. Thus there succeed the twistings writhings of Mr. Ross to prove the ultimate thermal and th fore cost inferiority of gas, while it could be done by a m simple process.

Its Development.

We cannot repress a smile over the point in the much-laboured case. Ross says "the prime economical advantage of gas lies in the fact that a current of air is ab lutely essential for the maintenance of the heat—involv (*a*) a free ingress of air to the boiling-ring, and (*b*) a defi minimum distance between the cooking utensil and the burn so that no back-pressure is put upon the jet." The scie underlying that statement is as difficult to find as is the rea for its appearance in a technical paper. There can be no c bustion for the development of heat without air is availab and the fact of complete combustion being obtained sh that, by the physical and chemical processes involved, the is—by the aid of the air, and in the circumstances of its us developing its full measure of heat. As to the distance betw the cooking utensil and the burner, this is necessary in or that the flames may not be checked, and so deprived of opportunity of developing their full potentiality in supply heat to the vessel above. Then our learned friend procee "From data variously collected, it would seem that when b ing for approximately four hours in a pot about 5½ in. diame anything from a minimum of 30 p.ct. to a maximum of 60 p of the available gas heat is lost, due to these essential co tions of burning. This fact is probably the most serious w which the gas people have to contend." In passing, it may pointed out that, if a pot only 5½ in. diameter was kept boil over a ring of gas-jets for approximately four hours, we afraid that, long before that time had expired, there would nothing left in the pot to boil—unless, of course, it was me kept simmering by nothing but a trace of flame. As to the l of heat due to the reasons our friend suggests, his minimum 30 p.ct. is nearer normal practice to-day than the maxim of 60 p.ct. As a matter of fact, the modern boiling-ring on hotplate of a gas cooker is quite capable of developing 70 p efficiency. We ask our friend whether he can suggest to any electric boiling plate which will at any part of its life continuously give an efficiency of 70 p.ct.; and is it not the that most electric hotplates will only develop (when new) to 45 p.ct. efficiency, and that a diminishing quantity with u It is no use Mr. Ross indulging in generalities if he cares reply, because experimental work has satisfied us on this p ticular point. Yet he deliberately states in his article t the electrical heat loss "appears" (which is not very positi to vary from a minimum of 5 p.ct. to a maximum of 12 p. because of the fact that the pot bottom may be as little as ¼ from the heating point. If he means by this that electric b ing plates will develop 88 to 95 p.ct. efficiency, we can accept the statement. However, Mr. Ross makes out th applying the correction for this particular loss, 1450 B.Th would be required with gas for the actual heat input 1000 B.Th.U. to the article to be boiled, while the correc electric power equivalent is 1085 B.Th.U. It is seen from own admission that the efficiency figures have been procu by more or less loose methods. He says they were obtained time measurement, combined with meter readings of consur tion, and also by "approximate" calorimetric methods, a he refers to the results as "reasonably representative." It usual in work of this kind to adopt scientific processes; and, order to judge of reliability, we should like to know more to what Mr. Ross actually did in this respect. On the evide of his articles we maintain distinctly and deliberately that th are not reliable. He has to face the fact that if he is rig then prior scientific work in this connection has gone astr though carried out by men of noted scientific attainments.

Further Gas Losses!

Our critic seeks to show that we guilty of further losses to add to previous waste delinquencies, and narrow still more the difference between the consumption heat energy supplied by gas and that by electricity. He found that the ribs across the hotplate for supporting the co ing utensils are responsible for a large loss of heat by cond tion and radiation. Mr. Ross appears to be ignorant of fact that the gas industry found that out long ago; hence reason that the construction of the top of most modern ty of gas cooker is such that no bars intersect the flames. T point might have applied a few years ago, but there is no n

ay to introduce the criticism, as it does not apply to the lern cooker. As a matter of fact, we have the authority of Hartley (who has made more cooker tests probably than other chemist or physicist) that the best gas cookers of the ent day show a saving of from 25 to 33 p.ct., compared n those of the pre-war period. Mr. Ross admits the difficulty iving definite data for heat losses; and then we have another mple of how crudely the data he uses have been arrived at. safeguards himself at this particular point by the use of word "if." "If thermometer readings are any rough cation, then for cookers of the same output, which very erally have the same top perimeter and weight of metal, it be found that, after the four hours' boiling referred to ve, and for the same cooking, of course, the following ap-ximate figures hold—viz., temperature round perimeter of plate for gas cooker 150° to 200° Fahr.; for electric cooker, to 100° Fahr. The average values are 175° and 75° Fahr. pectively." Then we are treated to a little reference to the ific heat of iron; followed by the statement that the heat essary to raise this mass to from 50° to 75° Fahr. works at about 51 B.Th.U. Similarly to raise it from 50° to 175° ir., about 255 B.Th.U. are required. These values, he es, will further alter the heat inputs in the example; and ie now become: Gas input, 1705 B.Th.U. Electricity input, 5 B.Th.U. per hour. To make it still more intricate, he is that the quantity of foodstuffs required to be cooked is n the electric cooker from 18 to 25 p.ct. less than that re-ed for cooking by gas. Whence he gets these figures, aven only knows. "Foodstuffs" which are cooked on a or any other cooker have a tremendous range; and we not imagine that any foodstuffs would (cooked by heat sup-d by one agent, and with equivalent temperatures and other ditions) play such foolish tricks as to reduce themselves e with the heat supplied by one means than by another. wever, the compiler of this queer article takes credit for monstrous proceeding on the part of foodstuffs. He says is advisable to consider two identical completely cooked erials, it being recognized that the quantity of material essary originally for the electrically cooked meal must be p.ct. (average) less than that required for the gas cooked al." In other words, for a gas heat input of 1000 B.Th.U., corrected electrical heat input is only 785 B.Th.U. Correct the latter figure for the various losses previously considered, ratio becomes 1705/903.

Finally. So, by these pretty contortions, Mr. Ross eventually arrives at the conversion of the ratio into a price ratio on basis of 10d. per therm for gas, and ¾d. per unit for electricity. It becomes 0·17d./0·199d.—that is, the gas charge is by 14½ p.ct. than that for electricity. Again this remark-e investigator says that observations have shown that, with electric cooker the net effective cooking time—*i.e.*, the time ing which current was actually flowing through the elements aried from 60 to 87 p.ct. of the time during which gas was ned for the same general meals. That is diametrically osed to the findings of other observers. Taking the average 75 p.ct., he holds that economically the ratio obtained must ther be corrected to take account of the consumption of p.ct. less energy with the electric cooker, due to the fact t it is more or less impracticable to keep on extinguishing relighting the gas, while (say) "pouring" potatoes, cab-es, and the like. Hence the consumption ratio becomes 5/689; and the charge ratio 0·17d./0·151d. The electricity rge is now 11 p.ct. cheaper than the gas charge. Con-ling, Mr. Ross reiterates that, intrinsically, electric cooking lefinitely not cheaper than gas cooking; but economically it o to the tune of approximately one-eighth. He has, how-r, the good conscience to acknowledge that he has taken a y low price for the unit of electricity, and that even then difference is so narrow between the competitive rates that price of ¾d. is much too high for successful competition inst gas for cooking purposes. It only requires, as he ognizes, a little lack of operative skill to cause the power s for electric cooking to take surprising flights. But after this laboured construction, there is a simpler plan of arriving efficiency and costs than the complex one which Mr. Ross arently prefers to adopt, and which would simply confound consumer. The input of thermal energy required for per-ning a definite amount of work covers all the debits and dits which he has discovered, and the price of that input is ertainable in every case. After all this, will Mr. Ross accept hallenge to do an equal amount of work with an electric ker (oven and hotplate) as with a gas cooker, at a cost for uel" of ¾d. per unit for electricity and 10d. per therm for , or 3420 B.Th.U. as against 7500 B.Th.U. for ¾d. in each e?

Growing Gas Consumption Per Head.—In a comparison be-en certain figures for 1923 and 1924, the Pacific Gas and ctric Company, of San Francisco, report that during last r the number of consumers in their territory increased by 706; while the gas sales per consumer rose from 39,800 c.ft. 2,400 c.ft.

FORTHCOMING ENGAGEMENTS.

[*Secretaries of Gas and Kindred Organizations are asked to assist in making this diary of events as complete and useful as possible by sending the earliest intimation of all meetings.*]

May 21.—British Commercial Gas Association, Manchester District (West Riding of Yorkshire Section) Conference, in the Harlow Manor Hydro, Harrogate, under the presidency of Mr. Francis Barber, the Chairman of the Harrogate Gas Company. Luncheon with the Chairman and Directors of the Company will precede the business, which will include an address on "Light and Health," by Mr. R. Veitch Clark, M.A., M.B. (Medical Officer of Health to the City of Manchester), and a paper entitled "Gas as a Public Service," by Mr. Frank H. Robinson, Assoc.M.Inst.C.E. (Engineer and Manager to the Harrogate Gas Company).

May 22.—Quarterly meeting of the Manchester District Institution of Gas Engineers, at the Harlow Manor Hydro, Harrogate. Mr. Frank H. Robinson, of Harrogate, will preside; and a general discussion will be opened by Mr. W. B. M'Lusky, of Halifax. A luncheon will be given by the Chairman and Directors of the Harrogate Gas Company, following which the members will inspect the gas-works.

May 23.—Half-yearly Auxiliary Meeting of the North of England Gas Managers' Association, at the Armstrong College, Newcastle-on-Tyne, at two o'clock. The chair will be taken by Dr. Geoffrey Weyman, of Newcastle. There will be an inspection of the Chemical, Physical, Engineering, and Metallurgical Laboratories of the College.

May 23.—Meeting of the Wales and Monmouthshire Junior Gas Association, at Treforest. Dr. Illingworth will give an address on "Low-Temperature Carbonization." Subsequently the members will adjourn to the Council Buildings, Pontypridd, to hear an address by Mr. D. Muir, on "Methods Adopted to Deal with Leakage in Colliery Districts."

May 26.—Seventh annual general meeting of the National Gas Council, at the Hotel Great Central, Marylebone Road, N.W., at 11.30. The President (Mr. D. Milne Watson) will present the annual report and statement of accounts.

May 28.—Meeting of the Wales and Monmouthshire District Institution of Gas Engineers and Managers, at Porthcawl. Mr. H. D. Madden, of Cardiff, will read a paper on "General Sales Propaganda."

May 29.—Sixth annual general meeting of the Chemical Engineering Group of the Society of Chemical Industry, at the Chemical Industry Club at 8.15. Mr. C. S. Garland, B.Sc., A.R.C.Sc., F.I.C., Chairman of the Group, will preside. The meeting will be preceded by an informal dinner in the Club at seven o'clock.

June 4.—Joint meeting of the Districts of the Southern Association of Gas Engineers and Managers, at Bournemouth.

June 5.—Visit of the Southern Association of Gas Engineers and Managers to the works of the Bournemouth Gas and Water Company.

June 6.—Annual outing, at Anstruther, of the Scottish Junior Gas Association (Eastern District).

June 9-11.—Annual general meeting of the Institution of Gas Engineers, in the Great Hall of the Institution of Civil Engineers, Great George Street, Westminster.

June 10.—Annual general meeting of the Association of Statutory Inspectors of Gas Meters, at the new County Hall, Westminster. The afternoon will be devoted to a visit to the Finsbury gas meter testing office.

June 11.—Visit of the Coke Oven Managers' Association (Midland Section) to the Barugh plant of Low-Temperature Carbonisation, Ltd.

June 12.—Visit of the Institution of Gas Engineers to Derby.

June 20.—Visit of the London and Southern District Junior Gas Association to the Cambridge Gas-Works.

July 9.—Visit of the Coke Oven Managers' Association (Midland Section) to the works of Messrs. Stainby and Lyon, of Knottingley.

Institution of Civil Engineers' Council.—The ballot for the election of the Council, at the annual general meeting of the Institution of Civil Engineers, resulted in the following elections: President, Sir William Henry Ellis, G.B.E., D.Eng. (Sheffield); Vice-Presidents, Mr. Frederick Palmer, C.I.E.; Sir Archibald Denny, Bart.; Mr. Ernest F. C. Trench, C.B.E., M.A., B.A.I.; and Captain Matthew H. P. Riall Sankey, C.B., C.B.E., R.E. (ret.). Other members of the Council include Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.; Prof. W. E. Dalby, M.A., F.R.S.; Sir Robert A. Hadfield, Bart., D.Sc., D.Met., F.R.S.; Sir Henry P. Maybury, K.C.M.G., C.B.; and Sir Richard A. S. Redmayne, K.C.B., M.Sc. This Council will take office on the first Tuesday in November next.

INSTITUTION OF GAS ENGINEERS.

Balloting List.

The following candidates have been approved for the next balloting list of the Institution of Gas Engineers:

For the Class of Member.

Ashworth, Richard, Engineer, Manager, and Secretary, Tamworth Gas Company.

Calderwood, Robert John, Gas and Water Engineer and Manager, Spalding Urban District Council.

Greenough, Peter, Gas and Water Engineer, Hindley Urban District Council Gas Department.

Robertshaw, Walter Livsey, Works Manager of the Ayre's Quay Works of the Sunderland Gas Company.

Surtees, Gilbert, Engineer and Manager, Uttoxeter Gas-Works, Ltd.

Watson, Alfred Thomas, Engineer and Manager, Rushden and Higham Ferrers District Gas Company.

Whatley, Greville John, Assistant to Mr. F. H. Jones, Westminster.

For the Class of Associate Member.

Carmichael, Stanley, Works Chemist, Avon Street Gas-Works, Bristol.

Dupont, Fernand, Chief Assistant Engineer at the Works of the Neath Corporation Gas Department.

Ely, Robert John, Assistant Manager of the Riddings District Gas Company.

Fall, Frederick Percy, Engineering Assistant and Chief Draughtsman to the Engineer of the Sunderland Gas Company.

Robson, Colin, Technical and Chemist Assistant, Elswick Gas-Works, Newcastle-on-Tyne.

Winch, Egbert Harold, Second Assistant with the Cambridge University and Town Gas Light Company.

Students.

The following candidates for studentship have been approved:

Calderwood, Robert Wallace, Assistant at the Gas-Works, Spalding.

Ware, Gilbert Charles James, Articled Pupil, Redhill Gas Company.

Williams, Rowland J., First Assistant Engineer and Manager, Gas-Works, Abertillery.

NATIONAL GAS COUNCIL.

Central Executive Board Meeting.

The Central Executive Board of the National Gas Council met on Tuesday, May 12, at No. 28, Grosvenor Gardens, S.W. In the absence of Mr. D. Milne Watson, the chair was taken by Mr. William Cash, F.C.A. (Vice-Chairman).

Nomination of Candidate for the Office of President.

It was reported that no nominations had been received for the office of President; and Mr. Milne Watson was unanimously nominated as candidate for the Presidency for another year.

Draft Annual Report and Statement of Accounts.

The draft annual report and statement of accounts were considered, amended, and approved for submission to the annual meeting.

Roads Improvement Bill.

It was reported that a conference of Public Utility Associations convened by the Council had met and considered this Bill, and had come to the conclusion that a protective clause in favour of statutory undertakings was required. Certain other amendments were moved, on the suggestion of the National Gas Council alone, for the purpose of ensuring:

(*a*) That the road construction experiments should be carried out only by an organization interested in the production of that material with which the road was being constructed.

(*b*) That the object of the experiments should be to discover a method of embodying British produced materials only—*e.g.*, tar, in contradistinction to bitumen.

(*c*) That there should be a representative Committee set up, similar to that appointed under the Traffic Act, to advise the Ministry as to the scope and nature of the experiments.

Certain assurances in connection with these experiments were obtained from the Minister when the Bill came before the Standing Committee.

Newport Corporation Bill.

It was reported that the Newport Corporation electricity undertaking had endeavoured to lay-down stipulations from time to time to the effect that the occupants of houses on estates belonging to the Corporation should use electricity for lighting and other purposes. At the instance of the Newport (Mon.) Gas Company, the matter had been argued at length before a Select Committee of the House, who agreed to the insertion of the following sub-clause:

(4) The Corporation shall not make or impose under the powers of this section any term, condition, or restriction with respect to the form of light, heat, power, or energy to be used in any house, shop, office, warehouse, or other building, or on any lands, or with respect to the taking from any particular local authority, company, body, or person of any form of light, heat, power, or energy.

Rating and Valuation Bill.

The provisions of the new Bill were discussed, particularly in relation to the new proposals which were made in connec with public utility undertakers. Consideration was also gi to the suggestions in the Bill with regard to the rating machinery.

After full discussion, the same was remitted to the Spe Rating Committee of the Council.

Factory and Workshop Act, 1901—Chemical Regulatio 1922.

It was reported that the "certificates of exemption" wh had, after considerable delay, been granted by the Home O to certain of the smaller gas undertakings, whose claims exemption had been submitted by the Council, were altoget inadequate, and afforded no relief whatever to the un taking.

A protest was being made both by the Council and by the undertakings concerned, with a view to obtaining further c cessions in regard to these Chemical Regulations.

Tar Exhibit at Wembley.

It was reported that a stand had now been erected Wembley in the Chemical Hall of the Exhibition, and was charge of an expert on tar for road purposes. It was also ported that the attention of road surveyors and chairmen Highways Committees throughout the country would be dra to this exhibit, and that they would be invited to visit it.

The Board authorized the Council's Tar Committee to serve space for a road tar exhibit at the Road and Transp Exhibition, to be held in November next.

Illuminating Engineering Society.

It was agreed that the Council should be represented u the Council of the Illuminating Engineering Society, and t Mr. D. Milne Watson should be asked to represent the Cou thereon.

Deputation of Scottish Municipal Representatives to Board of Trade.

A deputation to the Board of Trade was reported to h taken place on April 6, consisting of Mr. Campbell, of D fermline (President of the North British Association of Managers), and Mr. J. W. Napier (Secretary of the Scot District Executive Board of the Council), together with Mr. J. Fottrell. The deputation assured the officials of the Bo of Trade that the application of the Gas Regulation Act to S land had been very satisfactory and successful, and there no objection to it whatever, so far as the larger undertaki were concerned. It was felt, however, that, with regard the smaller municipal undertakings, there were certain seri difficulties in coming under section 1 of the Act—*inter a* the additional expense of providing the necessary testing stat and apparatus, the fee of the gas examiner, &c. In cases wh an undertaking has a small output of gas, with a limi number of consumers and a very small staff, the application Orders to such undertakings was likely to have a detrimen effect.

It was reported that this deputation had been sympathetic received; and it appeared probable that the thermal system charging would not be imposed upon the very small un takings.

Conference between Public Utility Associations at Ministry of Transport.

A conference was reported on the 7th inst., at the Minis of Transport, between representatives of gas, water, and e tricity interests on the one hand, and the County Councils' A ciation, the London County Council, representatives of Rural and Urban District Associations, and other bodies in ested in highway construction. It was reported that the ma arose out of a memorandum of the County Councils' Asso tion, in which they endeavoured, in brief, to remove all existing rights of statutory undertakers in regard to mains cables in highways, and, in fact, to make them revert to position of non-statutory undertakings.

As a result of this conference, a small Sub-Committee h been set-up, which was meeting immediately, and upon wh the gas industry was represented; and it was hoped to ag general principles, and to draw-up some agreed clauses sa factory to all parties.

It was further reported that the public utility undertak were asking for representation upon the new Committee set by the Home Secretary in connection with the law on diversion of highways.

Central Executive Board—June Meeting.

It was agreed that, inasmuch as the meeting of the Inst tion of Gas Engineers would be taking place on Tuesd June 9, the next meeting of the Central Executive Board sho take place on Monday, June 8, at 3.30 p.m.

Will.—Mr. Samuel Peter Austin, a Director of the Sunc land Gas Company, left unsettled property to the value £123,684 (net £123,338).

British Engineers' Association.—The new President of British Engineers' Association is Mr. H. J. Ward, of Mess J. & E. Hall, Ltd. (Dartford). He succeeds Sir Ernest Petter, who retired after holding office for two years.

WEMBLEY, 1925.

A week has performed wonders at Wembley; and no one could possibly in a single day see all that there is to be seen, though it appears to be generally agreed that large numbers of people have so far kept away by rumours of unreadiness. This is a mistaken attitude to adopt; for just now—when everything is perfectly new, when the grounds are a dream of beauty and freshness, and when the summer rush has not yet begun—is an excellent time to select for a visit. There is plenty of room to move about—too much, perhaps, may be the visitor's first reflection on entering, failing to bear in mind the vastness of the place. As a matter of fact, favoured by the glorious weather of last week—real Wembley weather, bright but not too hot—there had been, one gathered on Friday, up to that date at any rate, greater attendances than for the corresponding days last year. This is good augury for the success of Wembley, 1925. What the authorities desire should be inculcated in the Londoner is the "Wembley habit." Success in this respect would spell success to the Exhibition; for Wembley is within reach of a population of millions. With regard to the character of the attendances recorded, one learned on inquiry at a selling stall that "steady business had been done;" while the reply in connection with a propagandist exhibit was that "the right kind of people have been coming along."

Visits of Royalty.

Including the day of the opening, and a visit last Saturday evening to the spectacular display in the stadium, the King and Queen have already shown how close at heart they have the Exhibition by going to Wembley three times. On Thursday, they made a lengthy tour, and on all hands one hears of their keen interest in everything that they saw. Indeed, pictorial proof of this is to be found in the "Journal" to-day.

While in the Palace of Industry, the Royal Party made a full inspection of the Gas Exhibit; and here the King gave gratifying evidence—by a reference to the "Seven Ages of Woman"—of the lasting impression he had gained of last year's display.

Press View of the Gas Exhibit.

The Gas Exhibit was spic and span on Friday, when it was visited by a large number of representatives of the Metropolitan and Provincial Press, who were received by Mr. F. W. Goodenough, Mr. W. M. Mason, Mrs. M. A. Cloudesley Brereton, and others officially connected with the Exhibit. Among those present was noticed Alderman George Clark, J.P., M.Inst.Mech. E., a Past-Chairman of the Society of British Gas Industries.

The visitors appeared to be remarkably pleased with all that they saw in the Exhibit. This was only natural, for good as last year's arrangements were, the Gas Exhibit Committee and their Architect (Mr. H. Austen Hall, F.R.I.B.A.), and everyone responsible for carrying out their wishes, have on this occasion beaten their own record. A full description of the Exhibit will be found on pp. 458-460 of last week's "Journal," but the completed display is brighter and more live than it would be possible for any formal written description to indicate. In the Overseas Dominions Hall, in particular, there is a marvellously artistic effect—as one of the lady members of the party remarked, "the beauty of the setting of the Exhibit is perfectly wonderful." In a sentence, it has been appreciated that the arrangement of exhibits is an architectural problem which has to be dealt with in an architectural way; and Mr. Austen Hall has succeeded to a remarkable degree in doing this. While mentioning names of those responsible, omission must not be made of the contractors to the Committee, Messrs. Osborne and Co., of No. 2, Grafton Street, Bond Street, W., who naturally pride themselves on the results of their work.

In the case of the sight-seeing visitor, to look at one of the prettily-executed little scenes depicting the multifarious services of gas in the homes of the Empire, means to make an inspection of them all. The present or prospective gas consumer, domestic or industrial, will find examples of what is best in the way of apparatus for its utilization; while the housewife, desirous of gaining more knowledge with regard to cooking generally, or of one particular branch of it, will find herself immeasurably better off than was possible in 1924, owing to the great improvement effected by the provision of a separate quiet hall, 50 ft. square, devoted to frequent practical lectures and demonstrations.

Ask for Empire Products.

And more than cookery lectures with practical illustrations—highly important as these are to the home-life of the people—is to take place in the Demonstration Hall connected with the Gas Exhibit. Mention was made last week of the fact that a series of Empire food demonstrations is being organized to show that the Empire produces almost every kind of food that the consumer can require. There will be shown, not only a wide range and variety of Empire products, but the best and most economical ways of preparing them for the table. The object of these demonstrations is to familiarize the British public with the food products of the Motherland and Dominions and Colonies; and, in indicating their country of origin and the various ways of preparing them, to illustrate the almost limitless variety of food products within the Empire and the economic advantage of using them.

The Gas Exhibit Committee have promised to place all necessary plant and a staff of trained demonstrators at the disposal of the Empire Food Demonstrations Committee, on which the Women's Section of the British Empire Exhibition, the Fellowship of the British Empire Exhibition, the British Women's Patriotic League, the Empire Food Campaign, and the British Producers' Organization each have a representative. It is intended to give four cooking demonstrations each day, preceded by a short talk upon the nature and origin of one of the products to be used and the wholesale distributive agencies where it may be obtained. It is hoped to include every Empire food product, and to illustrate to the general public all such foods which are, or should be, available to United Kingdom markets. The British housewife who purchases Empire food products combines household economy with the exercise of a proper Imperial sentiment.

Ashtead Potters.

Another thing the Gas Exhibit Committee have done, which will meet with approbation far beyond the confines of the gas industry, is to provide space for a very interesting show of pottery-firing by the disabled ex-Service men employed by the Ashtead Potters, Ltd., Victoria Works, Ashtead, Surrey. Readers may be reminded that Sir Lawrence Weaver (Director of United Kingdom Exhibits) is Chairman of this undertaking, which it is hoped to make a permanent industry that will keep the men employed for the rest of their lives. All the profits (if any) will go back to the men employed; so that those making purchases of any of the pretty little articles on show in the Gas Exhibit will be supporting a thoroughly good cause. The Queen showed in a practical manner that the things on view met with her approval.

"Delaygue" Refrigeration Plant.

Another "working" display for which visitors to the Gas Exhibit—particularly during the week-end hot spell—have been manifesting a strong partiality, is the "Delaygue" refrigeration plant, the patents for which are owned by Refrigeration Developments, Ltd., of No. 86, Grays Inn Road, London, W.C.; the sole manufacturers for the British Empire being Messrs. H. J. West & Co., Ltd., of London and Saxilby. These appliances can be had in small sizes designed specially for ordinary household use, which are capable of keeping an average-capacity safe at a temperature of 38° Fahr. for 24 hours or more. The apparatus works on what is known as the absorption process; but no elaborate heating apparatus is necessary. At one heating—which takes about 45 minutes over a gas ring—approximately 3 lbs. of ice or 8 lbs. of ice cream can be obtained. The machine can be used indefinitely without recharging; so that the running cost is confined to that of the gas consumed for heating. The liquid employed is capable of giving off a large amount of refrigerating material by means of the application of a very small quantity of heat.

At the Sign of the Jolly Jack Tar.

There has been an addition to the British Road Tar Exhibit of the National Gas Council in the Chemical Section of the Palace of Industry. The photograph reproduced on p. 465 of the "Journal" for the 13th inst. showed the tar-macadam road passing round "The Jolly Tar" inn; but it revealed only a few minor branches of an apple tree in full blossom, which is to be found in the opposite corner of the exhibit. This tree, with a wooden seat surrounding it, imparts a delightful countryside touch to Mr. Norman Wilkinson's work; and now this effect has been heightened by placing on the tree two singing birds, which attracted the attention of the Queen during her visit last Thursday. Recording the incident, "The Times" said that Her Majesty "was surprised to find that art had simulated Nature so perfectly." The "Evening News" also had something to say on the matter: "A call was made by their Majesties at 'The Jolly Tar'—a house got up to look like an old English hostelry. The only fluid it contains, however, is tar used in road-making—not a suitable beverage for a day like this! What drew the notice of the Queen particularly was a pretty tree of apple blossom in the yard of 'The Jolly Tar.' Birds were singing in this tree quite sweetly. They are artificial, and the Queen expressed wonder at the close imitation of Nature."

The serious side of this display on behalf of "British Tar for British Roads" would, from all accounts, appear to be no less successful than its purely artistic side.

Glenboig Gas Retorts.

One of the displays in the Palace of Housing and Transport in which "Journal" readers will have a special interest is that of the Glenboig Union Fire Clay Company, Ltd., of Glenboig, and No 48, West Regent Street, Glasgow. They make special bricks for retorts and coke ovens, and claim that Glenboig fireclay is peculiarly fitted for the manufacture of gas retorts—being capable of resisting the highest heats, and combining with this characteristic the equally important quality of resisting sudden changes of temperature in a peculiarly high degree. Every detail is carefully considered by them, with a view to the production of retorts fitted to resist the higher temperatures and the more severe tests to which they are subjected in the modern

VIEWS OF THE GAS EXHIBIT.

[Photo. John H. Avery & Co.

systems of gas making. The Company claim to be the largest manufacturers of gas retorts in Great Britain; and that Glenboig bricks have long been famous is proved by the fact that two highly appreciative references to them are to be found in Vol. I. of "King's Treatise on the Science and Practice of the Manufacture and Distribution of Coal Gas," which was published many years ago.

Die Casting by Gas.

Mention was made in last week's "Journal" of the fact that the Monometer Manufacturing Company (1918), Ltd., of Bridge Street, Barrow-in-Furness, and Savoy House, No. 115, Strand, London, W.C., are in the Palace of Transport, again showing examples of their gas-consuming industrial appliances. Among these is their patent pressure die casting machine, which is made in one standard size.

The capacity of the pot is 200 lbs. of white metal, the plunger displacing 40 lbs. at each stroke; and the machine can deal with any metal with a melting-point up to 1000° Fahr. The machine is complete in itself, and only requires to be connected up to a 1-in. town gas main—no fans or blowers being required. The temperature of the metal is controlled by means

[Photo. John H. Avery & Co.

HER MAJESTY THE QUEEN INSPECTING MANTLE MAKING.

Lighting Trades, Ltd., have this year installed machinery for the making of gas mantles. The exhibit is situated in Nobel Hall, Bay E, Palace of Industry; and it is attracting considerable attention.

of a patent heat regulator, which prevents it from overheating and burning. This regulator is adjustable to any temperature, and once set requires no further attention. The "Monometer" die caster has a patented mixing device at the bottom of the plunger, which prevents the accumulation of the heavier metal at the bottom of the pot, at the same time ensuring a homogeneous alloyed casting. The melting pot is interchangeable; and there are no valves or other complicated working parts on the machine which might cause trouble. Owing to the design of the plunger and gearing, a big pressure can be obtained, which enables very intricate and thin close-grained castings to be made.

PHOTOGRAPHY BY THE LIGHT OF HIGH-PRESSURE STREET LAMPS.

Through the kindness of Mr. R. S. Ramsden, General Manager and Engineer of the Leamington Priors Gas Company, the permission has been obtained of Mr. W. Walden Hammond (also of Leamington) and the Editor of the "Amateur Photographer," to reproduce in our pages the above interesting photograph. The title of the picture is "Our Parish Church—Night." Mr. Hammond informs Mr. Ramsden that, when the photograph was taken, there was no moon, and the only light was that of the high-pressure incandescent gas-lamps on the tramway standards and that from the shop windows on the Parade. The block was placed at our disposal by the "Amateur Photographer"; and we thank them for their courtesy.

Small Stations at the Pithead.—Where a town is closely situated to a colliery, there is perhaps greater reason for a generating station being constructed there sufficient for its supply than for a super-station to serve many towns and generally over a large territory. In the former case, the question of condensing water, transmission costs and losses, safety, and reliability would not be so important as in the latter. The Workington Electric Power Company have built a station at the St. Helen's Colliery, Siddick, near Workington; and it appears to be a joint enterprise on the part of the Company and the Corporation. The former have spent upon it £40,000, and the latter £8000, whereas, had the Corporation carried out a scheme of their own, an expenditure of £50,000 would have been entailed. It is stated that the Corporation are going to receive current at a price which would not have been possible save for the utilization of what was formerly waste heat, but is so no longer. We look forward to hearing further particulars of the working.

PNEUMATIC HANDLING AND REVIVIFICATION OF OXIDE.

Simon Plant Installed at Nechells Gas-Works, Birmingham.

It has been abundantly proved by practical experience with a pneumatic plant at the Beckton Station of the Gas Light and Coke Company that spent oxide is definitely improved and revivified in the process of being handled pneumatically. As a matter of fact, at Beckton, material has been returned to the boxes within 24 hours, with satisfactory results. Mr. W. B. Leech, the Engineer at Beckton, has stated that the saving effected by the pneumatic plant over the old method of handling and revivifying oxide is in the neighbourhood of 2s. 6d. per ton.

It is not surprising, therefore, to find that other gas undertakings are adopting the pneumatic system of oxide handling; and Messrs. Henry Simon, Ltd., who were responsible for the plant at Beckton, have carried out several similar installations for gas companies, and have just completed the erection of a pneumatic oxide handling plant for the Birmingham Corporation at the Nechells Works. This plant has been installed in connection with a scheme for additional purifiers, which has recently been completed, and has been arranged to deal with the spent oxide from these new boxes.

The method of operation is simple, and the plant has been so arranged that it can be moved under its own power to any desired point on the various purifier floors. The floor space available over the new boxes for spreading out the spent oxide is 57,000 sq. ft.; and the whole of this area is reached by the pneumatic plant by means of rail tracks and turn-tables. The oxide, after passing through the pneumatic plant, can be delivered to any part of this floor by means of portable blowing-pipe connections. The spent oxide is lifted from the boxes by means of travelling grab cranes, and dumped into a feeding truck which is a separate unit of the pneumatic plant. From this truck the oxide is loaded on to an inclined mechanical conveyor which carries it to a hopper arranged above the disintegrator, and thence to the disintegrator itself, where the oxide is reduced to the desired degree of fineness. The powdered material falls from the disintegrator outlet into a rotary seal, which releases the oxide without leakage of air, and passes it into steel pipes, through which it is carried by a stream of air under pressure to the desired point, and there blown out on to the purifier floor. The plant has a nominal capacity of 10 tons per hour. The oxide is thoroughly aerated during this process, and complete revivification is obtained in a short period. The oxide, being subject to violent bombardment from the air stream during its passage through the pneumatic pipes, arrives at the point of delivery with the oxidization process more or less complete, and in a fit state for early return to the purifier boxes.

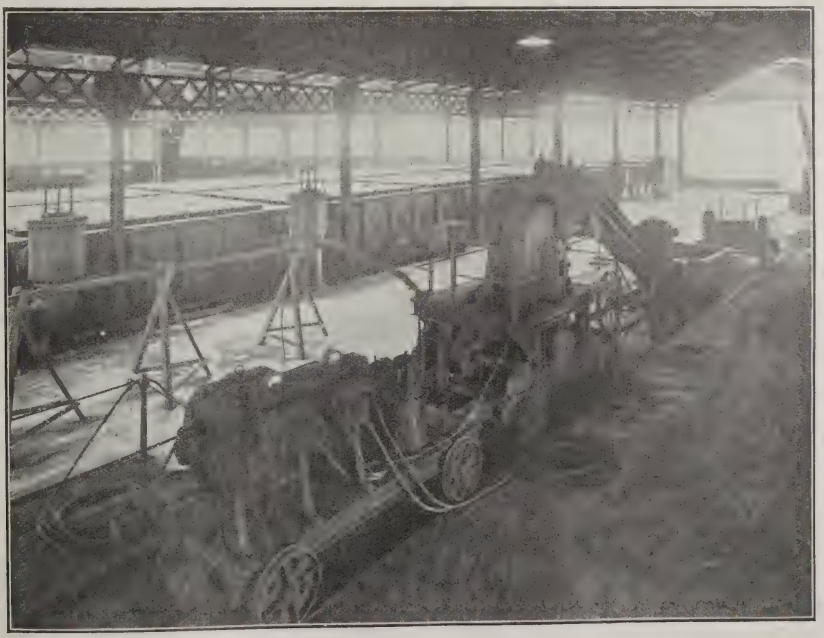
Carrying and hand spreading of the oxide is entirely obviated—a very valuable saving in labour thus being secured. The pneumatic pipe from the plant is supported on portable wooden trestles, and is provided with quick-coupling joints permitting additional sections of piping to be added easily and quickly, as required.

The pneumatic plant itself, the inclined conveyor, and the feeding truck are mounted on flanged wheels, and are arranged to travel on rail tracks which have been laid along each bay of the purifier floor. Turn-tables and cross tracks have also been provided at one end of each bay, so that the plant can be transferred from one bay to another.

The feeding truck and the loading conveyor are moved by hand, while the pneumatic plant itself, which is mounted on two trucks, is propelled, *via* suitable gearing and chain drives to the wheels on the rear truck, by an electric motor mounted on this truck. It is therefore a comparatively simple matter to move the plant to any desired position on the extensive purifier floor.

The disintegrator, rotary seal, and the motor for driving this portion of the plant are arranged on one truck; and the blower, the motor for driving it, and the starter are fitted on another. These two trucks are coupled-up, and are connected by a flexible pipe from the blower to the regulating valve below the seal. The disintegrator is of the Barry Henry type, running at 400 r.p.m., and reduces the oxide to a coarse powder. The pneumatic seal serves as a means of introducing the oxide into the air-tight system of the plant, and is of the rotary or paddle-blade type. This seal is so arranged that there can be no leakage of air when the oxide is passing from the disintegrator to the pockets of the seal. A relief pipe is fitted on the top, connecting with the atmosphere.

The rotor has a number of radial vanes dividing it into pockets, which fill in turn as they pass under the inlet port opening at the top. The pockets are released from the pressure of the delivery side on their way between the two openings in the casing by means of an escape pipe, so that there is no tendency to blow back when a charged pocket comes opposite the delivery opening in the casing. The material simply falls by gravity into the regulating valve. A regulating valve is provided below the seal into which the oxide falls after being released, and where it meets the incoming air under pressure. The blower is of the centrifugal type with an arrangement of balancing rings which limit the friction on the inner surface of the machine. The blower runs at 550 r.p.m., and is automatically lubricated by a small pump arranged at the end of the machine. At the outlet end of the blower is fixed an air receiver which carries a relief valve and pressure gauge. The suction end is provided with a filter which is specially coated to prevent dust getting into the interior of the blower. The motor is of the 3-phase type, 35 B.H.P., and is dustproof. The starters are of the usual oil-immersed pattern provided with "no load" and "overload" release. The motor carries a raw-



SIMON OXIDE PLANT.

hide pinion which engages with a machine-cut cast-iron wheel driving the blower.

The portable inclined conveyor is provided with its own motor and starter, and slip clutch on the motor. Flexible leads are provided to bring the current to the plant; and these are connected to plugs arranged at suitable points along the purifier floor. The arrangement of the plant is compact; and the handling and distribution of the oxide is carried out expeditiously and satisfactorily and with a minimum of labour.

The plant was designed, constructed, and erected by Messrs. Henry Simon, Ltd., of Manchester, who have specialized for some years in the pneumatic system of handling granular materials. It was mainly owing to the suggestions made by Mr. E. B. Tomlinson, Engineer of the Nechells Works, that the plant was made portable; and the increased effectiveness thereby secured has proved that his idea was a correct one.

CHARTERED INSTITUTE OF SECRETARIES.

Conference at York.

The Chartered Institute of Secretaries, of which Mr. James W. Slack (Managing-Director of Radiation, Ltd.) is the President, held their fourth annual conference on Thursday and Friday, May 14 and 15, at York—the North-East Coast, Sheffield and District, and West Yorkshire Branches taking a prominent part in the proceedings.

The business of the conference, in the Council Chamber of the Guildhall, was opened by an address of welcome which, in the absence of the Lord Mayor, who is in the United States, was delivered by the Sheriff of York (Mr. S. R. Slack). A paper on "The Position of the Secretary in the Industrial Triangle," by Mr. J. B. Bardsley, F.C.I.S. (Vice-Chairman of the Sheffield and District Branch), and Mr. Slater Wills, F.C.I.S. (Member of the Sheffield and District Branch Council), was read by the latter. The discussion upon it was comprehensive and animated. Mr. W. G. Hislop, of London (Member of the Council) and others, in the course of their remarks, dwelt upon the circumstance of the Secretary's potentialities in materially assisting the promotion of an improved understanding between the employer and employed. He had, in the rôle of mediator, many opportunities of exercising, by tact and judicious conduct, an influence for good, the important result of which could not under present industrial conditions be overestimated. The President pointed out that a trusted secretary enjoyed the respect and esteem of his Board, the staff, and the operatives. By reason of his personally disinterested position, he had opportunities of directing policy towards wise decisions, culminating in the happy relationship of all concerned in the welfare of the undertaking. The application of these principles to British industry generally would go a long way towards the restoration of industrial peace—a consummation of vital moment to the country's best interests at the present moment.

In the afternoon the Lady Mayoress, accompanied by the Sheriff of York, gave a civic reception at the Mansion House; and the conference dinner was held at the Station Hotel in the evening. Among the guests were Mr. Albert Procter (the Chairman of the York Gas Company) and Mr. H. E. Bloor, B.Sc., B.Eng. (Engineer, Manager, and Secretary); Alderman J. H. Waddington, J.P. (Mayor of Halifax and Chairman of the Gas Committee); Mr. Walter T. Dunn, M.I.Mech.E. (Secretary of the Institution of Gas Engineers and a Member of Council of the Institute); and Mr. T. P. Ridley (Secretary of the Newcastle-on-Tyne and Gateshead Gas Company). The Secretary of the Institute (Mr. C. H. Carpenter, C.B.E.) was, as usual, looking after the comfort of all, not only at the dinner, but throughout the proceedings of the conference. The toasts at the dinner elicited some excellent speeches. After the Loyal Toasts had been honoured, "The Chartered Institute of Secretaries" was given by the Sheriff of York. His remarks contained very appreciative references to the position of the Institute and the important work which it was so well accomplishing. The President acknowledged the toast, and expressed gratification at the progress being made in every department of the Institute's activities. Col. W. Parker, D.S.O. (Member of Council) proposed the toast of "The Visitors," which was responded to by the Mayor of Halifax in an amusing speech, and by Alderman E. Walker, of York.

On Friday morning the conference was resumed by the discussion on "Reserves and Reserve Funds.

Continental Union Gas Company, Ltd.—The Directors announce that an interim dividend of 3½ p.ct., less tax, will be payable on July 4 next on the preference stock, on account of the year ending June 30, 1925.

Allen's "Commercial Organic Analysis."—Messrs. J. & A. Churchill have published a new edition of this work, which has been fully revised and in part re-written. The sections on anthracene and naphthalene contain the latest methods of testing the crude and refined products in use commercially at the present time. The price of the volume is 30s. net.

OBSERVATIONS ON CALORIFIC VALUE AND GAS TESTING.

By B.Th.U.

[Communicated.]

Many recent papers and discussions have shown a widespread feeling that gas should be supplied of constant calorific value, composition, and pressure. It is voiced by men engaged on both the manufacturing and distribution sides of the industry, not merely so as to improve present conditions, but to equip the industry better for the more aggressive attack on the heating field—and particularly the industrial field. Given the *desiderata* named, specific gravity would be constant—that aspect which has only come into prominence in recent years in connection with the correct functioning of appliances.

The whole gamut of uniform calorific value, composition, and pressure is a big order; it can hardly be delivered, at least throughout the country, for many years yet. The industry must go one step at a time. Past history shows that caution has been a predominant characteristic, and to it much of the present prosperity is due.

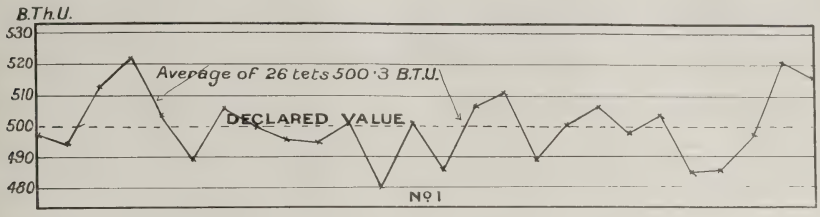
In the report given in the "Journal" for May 6 last of Mr. C. Bryan Donkin's paper "Gas for Industry," and the discussion which followed, Mr. J. Wilkinson, of Nottingham, raised anew the question of uniform calorific value. Mr. Wilkinson apparently doubts the wisdom of the present individual freedom given to undertakings of declaring that quality which best suits local circumstances; for he is reported as saying: "I am not at all sure that the time has not arrived for giving serious consideration to whether a uniform calorific value throughout the whole of the country would not ultimately be in the best interest of the gas industry." If there were no conflict between this ideal and financial considerations, &c. (as to which we need not enter into detail here), it might be readily conceded that the member who interjected "Hear, hear" was justified, not merely in his assent to the suggested consideration, but also to the implied belief that a uniform calorific value would be beneficial.

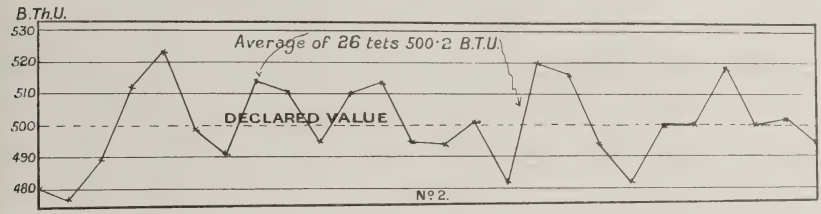
But is uniform calorific value the first step in the order of progress? If it were already attained, the other physical contingencies referred to would be less difficult of realization; one factor in the compound problem would have been removed. It seems, however, hardly a proposition to be seriously entertained until all gas undertakings have learned to maintain uniform calorific value at the respective declarations which they have already made. In other words, before general uniformity is put up for settlement, it is mete that individual uniformity should be determined.

Since the Gas Regulation Act, 1920, came into operation, about 570 undertakings in England, Wales, and Scotland had applied for and obtained Orders under section 1 up to Dec. 31 last. Out of this number over 80, or about 14 p.ct., had revised their declarations; and in a few cases there had been more than one revision. The cause of revision has probably been either (1) a recognition that the original declaration was not a true reflex of existing working, or (2) modifications in plant resulting in a different calorific value being the most convenient to manufacture. Whatever the cause, the convenient flexibility of sub-section 4 (*b*) of the 1920 Act, which gives power of alteration, has received substantial support in so large a percentage of amendments.

Under the Regulation Act, provision is made for independent testing of the gas; and gas examiners have been appointed to discharge these duties in the great majority of areas now supplied under section 1. The prescriptions drawn up by the Gas Referees provide that the gas examiner shall issue a quarterly report of all the official testings made, and "no average calorific value shall be reported for any less period than a quarter." Thus the figures which are published afford no indication of the fluctuations which may have taken place during the quarter. It is seen from the reports appearing in the Technical Press that many undertakings have come very close indeed to the declared value in the quarterly averages. A superficial observer might assume from this that individual undertakings, though not obliged to supply at a "national" calorific value, were able to supply, and were actually supplying, uniformly at the "local" value. But in actual practice this is far from the case, especially where daily official tests are not made. A 6 p.ct. deficiency is allowed before penalty arises for not supplying according to declaration; and so long as an undertaking keeps above that minimum, there will be no publicity of deficient tests. The item "Number of days on which the calorific value was deficient by 6 p.ct. or more," on the quarterly report sheet, will be followed by a "0."

Assume an undertaking gets down to 471 and, *per contra*, for equalization purposes, goes as high as 529 on a declared value of 500 B.Th.U., there is a variation (calculated on the declared value) of nearly 12 p.ct. The writer makes no point of whether or not such a variation is desirable. As it is one allowed by the prescriptions, it may be assumed that, so long as it is no more than 12 p.ct., the interests of the public are held to be fairly safeguarded. Here follow the actual official tests of an undertaking made over two consecutive periods, put in graphic form:





It will be seen that in No. 1 the variation is from 522 to 80 B.Th.U., and in No. 2 from 524 to 476 B.Th.U. Moreover, there is much jumping up and down, both graphs having many peaks and depressions. The graphs refer to an undertaking which would be classed as "medium to large," and one that is under excellent management. It is safe to assume that, were we permitted to enter the archives of the Gas Registrees and look at the quarterly reports of other undertakings, we should find that there were many of which these graphs are typical.

Implications of Considering General Uniformity.

Now, if the question of the desirability or not of imposing on the gas industry, voluntarily or otherwise, a uniform standard of calorific value throughout the country is to be discussed, it follows as a natural sequence that the first thing a gas engineer or manager must do is to look at his own performances in the direction of uniformity. It follows, too, that what the gas industry has achieved in its effort to comply with official control will come-up for examination. The future can only be prescribed for by regard to what has been accomplished and shown to be practicable in the past.

It is worthy of consideration as to whether gas undertakings are prepared or willing to have more publicity in connection with official tests—*i.e.*, publicity in greater detail. It is not difficult to see that, should a fairly general feeling be declared in favour of uniformity of calorific value throughout the country, one of the things that would precede its attainment would be more public information as to the quality that is already being supplied. This publicity would focus more and more the eyes of the consumers on the gas undertaking. It is conceivable that what is now a tolerable statutory injunction would become nothing more or less than a whip in the hands of pertinaceous consumers with which to belabour the gas undertaking.

If general uniformity were agreed upon, would the uniformity be based on a standard with a 6 p.ct. margin either way? The rejoinder at once is that this is no guarantee of uniformity. Mr. Wilkinson spoke of the margins of 280 to 360 B.Th.U. These figures in their nakedness are very far from fairly reflecting the real position. They give the impression that quality ranges to-day by 100 p.ct. upon the lowest figure. As a matter of fact, there are only four undertakings which have a lower declaration than 400 B.Th.U. These are as follows (annual sale in million c.ft. in brackets): Bungay, 360 (7); Goring, 320 (18); Nuneaton, 280 (119); and Scunthorpe, 375 (112). In considering the general proposition, these undertakings are negligible, totalling no more than 876,000 therms altogether. There are only 56 undertakings, including these four, with a lower declaration than 450 B.Th.U., and 13 of these are in Scotland.

There are 24 undertakings with a declared value of over 500, but not exceeding 560 B.Th.U.; and one, Lampeter, which has declared 600 B.Th.U., and sells less than four millions. Thus, of the 570 undertakings with declarations at Dec. 31, 1924, nearly 500 already declare at between 450 and 500 B.Th.U., and of these actually 160 have declared at 500 B.Th.U. It is an exercise for which the writer has not the inclination, but which might tempt a statistically-minded reader, to calculate from the individual declarations what proportion of gas this 500 B.Th.U. declaration represents on the total. As it includes the Gas Light and Coke Company, it must be in the neighbourhood of 50 p.ct.

When the figures are fully examined, it is probable that they will reveal a much closer approximation to uniformity than superficial consideration leads one to think. If a range of 50 B.Th.U. were taken (say 440 to 500 B.Th.U.) it would probably be found that 70 to 80 p.ct. of the gas sold under section 1 is already within it.

Does the question, then, not boil-down to this—that if undertakings will successfully strive to keep the quality at the declared figure, uniformity to a greatly preponderating extent will have been accomplished, without any tinkering with the present legislation, or provocation for tinkering? If Mr. Wilkinson had in mind no more than a "consideration" having for its object the peaceful persuasion of gas suppliers to deliver at a uniform quality, that "movement" can achieve a great deal, if it produces close synchronization between the supply line of quality and the line of declared value. Even before that can be urged to the full, there is another "movement" overdue—that of those municipal undertakings which have so far elected to remain outside the fold of the Gas Regulation Act, getting inside. On a point of urgency, this takes distinct priority over the question of a uniform calorific value. Until these undertakings come in, and declare what quality they can most conveniently supply, it is not possible with completeness to test the measure of present dis-uniformity.

Qualifications of Gas Examiners.

No steps have been taken as yet to enforce a standard of qualification in persons who are appointed to gas examinerships. The attainments of those who are appointed vary widely, as also the remuneration for the duties performed. Those who make appointments are guided merely by an exhortation to appoint only qualified men, without any indication as to what qualifications to look for. There are examiners with so many appointments that it is a wonder how they are able to do justice to all of them. It is a matter for consideration whether some closer regularization cannot be given to persons who are entrusted with so important a matter as reporting on the quality of the gas supplied under statute. The Metropolis is reputably well served. It is in the Provinces that wide disparity exists.

In conclusion, the summarized position seems to be that, if the gas industry can be assured that throughout the country the gas is being efficiently tested with reliability, reflecting the true quality, and can keep at all times closely to its declared value, the case (if there is one) for general uniformity, or one common quality, will, in the writer's view, be found to be considerably weakened.

Distribution Conference in America.—In connection with the American Gas Association, there has been arranged a two-day distribution conference, which will take place in Detroit on June 11 and 12. The purpose is to afford distribution engineers an opportunity of discussing vital problems; and various pressing topics have been selected for consideration.

The Industrial Gas Field.—The Survey Committee of the American Gas Association have been considering the data which will be embodied in their report to be presented at the convention in October. In connection with their work, the Committee are preparing data on all of the gas properties in the States of New Jersey and New York, showing the gas sales for the year 1924, divided into domestic and industrial sales, and the percentage of sales and revenue in each class to the total business. These data will be summarized in the classes of business, indicating the amount of potential business available in 1000 c.ft. of gas, and the rate necessary to secure the business. The idea is to show that, if gas utilities were securing this business and displacing other fuels, the industrial gas sales, instead of being from 20 to 25 p.ct. of the total gas sold, would amount to from 40 to 60 p.ct.

"B.C.G.A." SOUTH-WESTERN DISTRICT CONFERENCE.

REPRESENTATIVE ASSEMBLY AT MINEHEAD.

THE South-Western District of the British Commercial Gas Association held a conference at the Plume of Feathers Hotel, Minehead, on Friday, May 8. The chair was taken by Mr. J. H. ELLIS (the President of the Association, and Chairman of the Plymouth and Stonehouse Gas Light and Coke Company). Not only were delegates present from the majority of the gas undertakings within the area, but an equally satisfactory feature of the attendance was that all sections of the industry were adequately represented—the size and character of the gathering being regarded with extreme satisfaction by the Directors, shareholders, and officials of the Minehead Gas Company, who were the hosts for the day.

Mr. JOHN BURGESS, J.P. (Chairman of the Minehead Gas Light and Coke Company, and the Minehead Urban Council), welcomed the members in the name of the Council and the Company. He was sure the conference would be helpful to them in the exchange of ideas, which was so essential to efficiency in the control and management of gas concerns. Minehead was a most prosperous town; and taking into consideration the population and the rateable value, he thought it had made greater progress since the war than any other place in the country. The Gas Company were progressive, and the output of gas had increased every year for a considerable time—even during the war. He congratulated Mr. Ellis on his election to the Presidency of the "B.C.G.A.," and said those who had had the pleasure of listening to him in different parts of the country must feel that he was the right man in the right place. He was expressing this appreciation on behalf of the Directors of the Minehead Company, but he might go further, and say it was an opinion fully shared by everyone in the Association. [Applause.]

PRESIDENT'S ADDRESS.

The PRESIDENT said he took what had been said of him to belong more properly to the organization of which he had the honour to be the head. The policy of the "B.C.G.A." was to encourage those conferences for the interchange of views and experiences, for the benefit of the industry. The one purpose which animated them all was to serve the public honestly and well, and to give those on whose support they depended the best value for their money—not merely in the cheapness of the commodities they supplied, but in the brightness and comfort of their homes, in the removal of domestic drudgery, and in the purity of the atmosphere of the towns which the extended and extending use of gas brought.

Perhaps he might call attention to the results of this policy, as revealed by the following figures:

Output of Gas in the British Isles.

Last year	281,874,000,000 c.ft.
The year before	269,602,000,000 ,,
Increase	12,272,000,000 ,,

Number of Consumers.

Last year	8,502,069
The year before	8,406,172
Increase	95,897

Cookers and Grillers Supplied.

Last year	5,450,093
The year before	5,133,190
Increase	316,903

The outlook of the Association was world-wide; and while there were many respects in which the Americans might with advantage follow us, there were others in which we seemed to be travelling along the same road, and some where we might profitably follow them. High-minded competent administrations on both sides of the Atlantic were agreed it was their duty, as well as their interest, to minister to the public well-being. In pursuit of this object, they must be candid and frank with their customers (the public); and they must never tire of giving the wildest circulation in the Press, on the platform, in exhibition halls, and in their offices, to the benefits which followed the happily increasing use of gas in streets, factories, and homes. Let them be careful to tell the truth not merely about themselves, but also about their competitors. For years he had been associated with both gas works and electricity works, and the successful conduct of each was mutually advantageous. Not only so, but extended experience convinced him that if both were more often in the same hands, as they were in some places, they would be administered more to the public advantage than was frequently the case.

Dealing with the suggestion repeatedly made that the Government should subsidize electricity, the President asked, "Was electricity in such a bad way as that?" Figures were given showing dividends from 10 to 15 p.ct. on electrical undertakings. How many gas undertakings were allowed to pay such dividends as those, and what sliding-scale that was ever thought of would permit them? Members of Parliament with whom he had talked on that subject said it was only intended to subsidize water-power schemes, such as the Severn. Did they suppose, if the present Government or any other Government were guilty of the injustice of taking their money or speculating with it on the Severn or similar ventures, they would ever have a farthing of principal or interest, or would get electricity a farthing a unit cheaper than they would obtain it from the electricity company, or than Mr. Vince (the Manager of the Minehead Gas Company) could produce it for them by a gas engine? He suggested that everyone present should ask his Member to be on his guard against any insidious proposal made, and to resist it. Let them depend upon it that, if they were vigilant, the public would see to it that injustice was not done to the thousands who depended on their industry for their livelihood.

At the invitation of Mr. W. N. WESTLAKE (Exeter) seconded by Mr. S. J. INGRAM (Truro), the conference accorded thanks to the President for his address.

PUBLICITY WORK OF THE ASSOCIATION.

Mr. W. M. MASON (the Manager of the "B.C.G.A.") then dealt with the publicity operations of the Association—specially commending the Wembley Exhibition last year as an example of what could be done in the way of advertising. The Association was out to benefit the gas undertakings, and nothing gave those officially connected with it greater pleasure than to be of use. Undertakings had a perfect right to look to the organization to assist them in overcoming difficulties, and to be a help to them in every form of development. He was hopeful regarding the future, both of the Association and of the industry it was seeking to promote, believing that, by all working together, still greater success awaited them. It was by constant and well-directed efforts of the individual units, backed by the whole strength of the central organization, that future triumph could be assured. Never let those present forget that the Association under whose auspices they met that day was their organization, and that its main object and chief purpose was to help in the development, and secure the improvement, of the whole gas industry of the country. He had a strong belief in the value of publicity, and a confident opinion that, if wisely used, it would serve to show, in ever more striking and convincing way, the value of gas to the community in its upward march along the path of progress and civilization. The future was with them, as promoters of this great agency for giving light and heat, if only they seized their chances courageously and went forward without fear.

Mr. EDWIN P. VINCE (Manager and Secretary of the Minehead Gas Light and Coke Co., Ltd.) read a paper, from which the following extracts are made:

LOCAL PUBLICITY AND SERVICE METHODS OF A 50-MILLION WORKS.

It has been said that it is impossible for two lighting companies to exist and pay their way in a town of under 6000 people; but this has not been our experience or that of our competitors. In 1807 we made 8 million c.ft., in 1915 23 millions, and in 1924 over 48 millions. I should like to emphasize the fact that our policy is *pro* gas, not *anti* electricity. Indeed, if there were no electricity available in Minehead, I should not hesitate to recommend my Directors to get power to supply it.

An outline of the method by which we have increased our sales may be of interest to you. First I would like to pay tribute to the excellent organization and officers of the British Commercial Gas Association, the mainspring of the selling side of every up-to-date gas undertaking. I look forward to the day when there will be a 100 p.ct. membership. Those companies who are outside our organization are benefiting by the co-operative advertising; but happily the proportion is fairly low. In most cases they are probably undertakings with a very low standard of efficiency. If they were really keen, they would be members of the "B.C.G.A." as a matter of course. Every undertaking has a duty to the industry as well as to itself—viz., to give a high standard of service.

The greatest asset in developing the sales organization of any industry is the goodwill of the public; and this can only be obtained by persistent, conscientious, and faithful work—viz., service coupled with boundless enthusiasm. We must all realize that, in spite of the general growth of gas sales throughout the British Isles, we have only touched the fringe of the possibilities of gaseous heating and other uses for gas. While there is a single chimney emitting smoke, we must never rest.

Good advertising is a great asset to any business concern, ovided it is backed-up by service; the one is of little benefit ithout the other. Spasmodic advertising, however, is of very tle value, if any. We advertise in our local Press every eek; and the subject matter never appears more than once. e realize to the full that it is one of the greatest essentials effective newspaper advertising that copy should be regularly anged. Furthermore, to be of any value, the advertisement ust catch the eye. To achieve this end, we always have an ustration. The reading matter, which must never be over-owded, is headed by an apt phrase in bold type, and the whole surrounded by a distinctive border. Also we stipulate for a sition over news columns, with no other advertisements near . "White space" advertising, too, we consider to be an ective, if somewhat expensive, method for occasional use, hile a paragraph every now and again in the local news ıdoubtedly has its uses. We always endeavour to frame an lvertisement to educate the public up to the utility of the rticular apparatus referred to; and in this connection I ould like to pay tribute to the assistance we have received ɔm the "B.C.G.A." and also to one of the members of our rical staff, who has shown particular aptitude for the work. ɔod advertising is like the proverbial snowball—at first it ıthers slowly, but later on the result is apparent.

I should like to emphasize the need for every gas company, wever small, to possess a showroom. For several years I rved companies without showrooms; and I can speak from rsonal experience of the difficulty in securing new business hen one can only show to the prospective customer an illustra-ɔn of the particular appliance required. Happily for me, my irectors, at the instigation of the late Mr. Reginald Thomas, y predecessor here as Manager and Secretary, secured good emises as showrooms and offices in the centre of the town; ıd other property has since been acquired for future exten-ɔns to meet our growing business. I say without hesitation at, without these showrooms and offices, it would have been ıpossible to increase our sales as we have done.

Our aim has been to show how gas can be employed to crease the amenities of the home or the potentialities of a ısiness. Having regard to the fact that this is a holiday re-rt, I hope, when our additional premises are available, to -up a section showing the many advantages of gas in hotels ıd boarding houses. There is a real need for this, as one ten finds obsolete and extravagant apparatus in use. A well-ghted showroom window display is at all times a potential ısiness getter, and additionally so if lighted after the usual ısiness hours.

As regards canvassing for new business, it is questionable hether postal canvassing is of much use in a small town. I ink one interview is worth a dozen letters, and certainly is r more satisfactory in the long run. Neither am I impressed ith my one experience of employing a canvasser. The best ısiness getters are a staff who know their work and do it fficiently. I am glad to say my staff introduce a lot of busi-ess, because they are keen on their job. The question of gular inspection of all gas appliances, and testing of installa-ɔns, in order that the highest efficiency may be assured, has ven many engineers cause for thought, and in some cases tion. I am convinced that customers and gas companies ike would benefit by its general adoption. We have not been ble to do this yet, but I hope to see it put into effect.

The enhanced cost of gas appliances since the war makes it ıperative for companies who are not in the position to resume ıeral hire terms to adopt a system which helps an intending ırchaser to have the best and most efficient appliances. Many our clients appreciate, and take advantage of, the facilities e afford them to spread payments over two or three years at very small extra cost—viz., 5 p.ct. for two years or 7½ p.ct. r three years. As we offer to deduct this percentage from the nount remaining unpaid, if at any time a client is in a posi-ɔn to clear the account, it happens in a large number of cases ıat, after a successful letting season, the balance is paid off. bout 500 houses have been erected in Minehead and district nce the Armistice; and the whole of these, with two excep-ɔns, were serviced and piped for gas during the course of ection. The pipes are so arranged that it is possible to have gas fire fixed in any of the rooms. It is obviously good busi-ess to do this.

One of the best advertisements any company can have is ɔod outside lighting of shops. Under our scheme we make a xed charge per lamp for hire and maintenance. This system good for the trader and for the company. Each year since e inaugurated the system we have had the pleasure of gaining ıore business. The effect on the minds of the public through ways having good examples of gas lighting before them ıould not be lost sight of. We have also a fair share of inside ıop lighting, which we do on similar terms. The number of ıtside lamps is 70, and inside lamps 106. In the aggregate ıey afford us an appreciable load.

The domestic servant problem is becoming more difficult very year, and is probably felt to a greater extent in a seaside wn than inland, especially during the summer season. A linehead lady informed me the other day that the board and ages of a good servant in Minehead to-day are equivalent to ;100 per annum, so that, if she could reduce her staff of servants by one, through the adoption of gas for heating and cooking, it would be a profitable transaction for her.

Many of the hotels and boarding-houses here have adopted gas fires with separate slot meters in the bedrooms; and without doubt, as the idea becomes more generally known, this business will increase enormously. In this connection a letter we received from Bournemouth will interest you.

"Boscombe, Bournemouth,
Dear Sirs, *Jan.* 28, 1924.

Will you be so good as to let me know which of the private hotels or board residences in Minehead have gas fires with ring fixed in the bedrooms? I am anxious to visit Minehead early in the spring, and should be glad to know this. I see in one of the guide books that you will be glad to supply this information. We have gas fires in all the bedrooms here, and they are such a convenience to all in the house.—Yours faithfully, &c."

The good use of this letter as the basis of an advertising campaign secured us a welcome increase in this class of business, while many cases of new installations in the same direction have resulted through the personal recommendation of one boarding-house keeper to another.

Much may be done also in the way of educational propaganda. For instance, we are always glad to co-operate in any local cookery classes or competition for adults or children, by offering prizes for cooking by gas. The money is well spent, especially where the children are concerned, for they are our customers of to-morrow.

In conclusion, I should like to point out that a scheme of publicity which might be applicable to one district might not be so well suited for another. Each district must work out its own salvation. Whatever form of publicity is adopted, it is often difficult to trace the business actually resulting; but in the writer's opinion good advertising, backed-up by good service methods, is the *sine qua non* of successful management.

Discussion.

Mr. P. S. Hoyte (Plymouth) enlarged on the value of showrooms, and adduced several arguments to support his view. Without decrying the value of the written or the spoken word, he insisted that practical demonstrations made the greatest impression on the public mind. In showrooms persons could see what no amount of printed or spoken matter could convey. He urged the establishment and maintenance of showrooms, replete with the most modern devices and improvements in heating and lighting by gas. It was the best advertisement any company could invest money in. Such showrooms should be rendered attractive, be made easy of access, and be in charge of an employee who was affable and well posted on all points. Advertise, by all means, in every way possible, by circulars, in the Press, upon the hoardings. Use pictorial matter whenever practicable. But do not suppose that, when that is done, everything is done. In other words, do not forget the showroom.

Other members taking part in the discussion testified to the use and value of showrooms, and several spoke in appreciation of Mr. Vince's paper.

Luncheon.

Later the members were the guests of the Directors of the Minehead Gas Company at luncheon. Mr. John Burgess presided, and was supported by co-Directors and by officers of the "B.C.G.A." At the conclusion, there was one toast—the President inviting the company to drink to "The Chairman, Directors, and Manager of the Minehead Gas Company." He expressed his warm appreciation, and that of the members, of the way in which the Association had been received and entertained that day. Mr. Burgess briefly replied.

The Modern Labour-Saving House.

The afternoon session (open) drew a crowded attendance; the accommodation of the Assembly Room at Newcombe's Café, in the Parade, being severely tested. Ladies greatly predominated in the audience. Home hygiene and its relation to gas, to be expounded by a lady, was evidently a powerful attraction to housewives.

The President, in a few introductory remarks, said Mrs. Robert Noble was known to them as consultant on home hygiene, furnishing, and equipment. The topic upon which she was to speak to them, which she would treat as an authority, was "The Modern Labour-Saving House."

Mrs. Noble said she understood that 90 p.ct. of the population of Minehead used gas appliances, but that still a number of houses detracted from the health-giving attributes of the town by burning coal and adding smoke to the atmosphere. As a delightful resort, Minehead must live up to its reputation for fresh air and sunshine, by offering a maximum of both; and this could only be done by eliminating all the coal fires that vitiated the atmosphere. It seemed a pity that the whole community should be penalized by the few. There were homes so efficiently run and intelligently equipped with gas cookers and gas fires for heating the rooms that, although there was abundant warmth in them, there was no vitiation of the atmosphere by smoke and the products of incomplete combustion. The owners of such houses found the labour of housework so lightened that they had more time for rest, recreation, and leisure. But what happened time and again was that the leisure so won was spoilt. The skies were heavy and overcast, fog and smoke lurked in the atmosphere, and the leisure hours spent out of doors were robbed of part of their health-giving

properties by the smoke and soot rising from the open coal fires of the unenlightened householder. All true housewives should strive to make their own house ideal; and both husband and wife must join forces to bring about these ideal conditions.

The real labour-saving house saved time, steps, and money, and conserved health and energy. The work was better done and in less time, leaving a wider margin for rest and recreation. Thus in a community of real labour-saving homes the citizens enjoyed more ideal atmospheric conditions during their leisure; and they also had a good conscience, knowing that each had honestly done his or her bit to ensure a smokeless city. The intelligent servant welcomed the real labour-saving device that simplified housework. Gas appliances really did save time and trouble by lightening work, by providing adequate hot water, and by supplying a hygienic source of warmth, with a maximum of efficiency at a minimum of cost in both cash and energy.

Many mistresses who could provide their staff with a sitting room found the gas fire exactly met the case. The room was needed at odd times, and it was so easy to light the gas fire for just so long as it was wanted and no longer. In the kitchen, which was the workshop of the home, when gas was intelligently used, the preparation of the meals and the clearing-up after them, the work of washing day and all house cleaning, were considerably simplified. In connection with hot water the coke boiler must also be considered. In every room of the house the story was revealed of how gas helped the housewife to make a real home. From attic to cellar the value of gas appliances and gas fires in promoting the health, comfort, and well-being of the whole household could not be over-estimated.

The President said they were extremely obliged to Mrs. Noble for her address.

Some ladies put questions. One of them asked whether a gas fire in a room helped to promote sociability to the extent that everybody knew an open fire did.

Mr. Vince replied that personally he felt as much sociability under the influence of a gas fire as before an open grate.

Mr. Mason urged the value of labour-saving appliances in the home, as advocated by Mrs. Noble. Their industry happened to coincide with the public welfare. They were offering the public something that was needed, and would help tremendously to solve the problems of the household. In Minehead they were fortunate in having a progressive gas company. Let them go to the showrooms, and they would be surprised at the wonderful service they could get.

The President said, with regard to cooking, everybody was agreed that it was now nearly all done by gas. In Leicester 95 p.ct. of the population cooked by gas; and in Plymouth they had a trifle of 14,000 cookers out. The Gas Company were discontented, however, because 2000 or 3000 of their customers did not cook by gas; and they were giving demonstrations showing how advantageous it was to cook by gas.

Mr. Westlake said that Exeter was extending its houses rather rapidly, and during the last four or five years 95 p.ct. of the new houses had been built without coal ranges being installed. Cooking by gas was looked upon almost as a universal necessity. In Exeter a group of 45 houses had just been completed, and there were no coal ranges in any of them. They had done away with chimneys in the upper storeys altogether, and had put in 9 in. by 3 in. flues, and gas fires in two bedrooms. These had proved so acceptable that they were now being pressed to instal them in the smaller industrial houses.

Mrs. Noble was thanked for her address, on the proposition of the President, seconded by Mr. Burgess.

Gasholder Fire at Pittsfield (Mass.).

Illustrations appeared in a recent issue of the "Intercolonial Gas Journal of Canada" of a gasholder fire at Pittsfield (Mass.). When workmen were on the steel framework of the holder attending to the steam pipes for heating the sealing-water, a film of oil floating on the lower water-seal, from some cause unknown, became ignited. The film of oil was probably very thin, and the flames at first reached a height of only 2 or 3 ft. The burning surface, which was 18 in. wide, extended round the whole circumference of the holder—about 330 ft. This oil fire would doubtless have burned itself out in a very short time, without causing appreciable damage, had it not been for the introduction of complications. The holder was a three-lift one, in a steel tank, and had a capacity of 750,000 c.ft. At the time of the occurrence it was almost full of gas, which was expanded by the heat from the burning oil to such an extent that the holder rose to its utmost height, and the gas then blew out around the bottom water-seal. This escaping gas, of course, became ignited, and further increased the heat, with consequent additional expansion and escape of gas, which provided fresh fuel for the flames. About 200,000 c.ft. of gas was consumed in this way; and at the same time, it is said, the oils which had over a long period condensed out of the gas, and were floating on the surface of the water inside the holder, were forced out, and also caught fire. Any danger there might have been of a collapse of the structure was obviated by keeping the steelwork cool by means of streams of water from the fire hoses constantly playing on the supporting frame.

GAS PRODUCED FROM HEAVY OILS.

The possibility of competition with town gas from gas generated from heavy fuel oils by partial combustion, was mooted in the course of a paper read at the meeting of the London Section of the Society of Chemical Industry on Monday, May 4. The author was Mr. J. E. Hackford, who has been responsible for the technical development of the "Hackol" gas process, in which heavy bunker oils of 0·950 sp. gr. and upwards are contemplated for use. The author pointed out that these oils are not universally satisfactory for use in high-compression engines, and consequently it is not surprising to find that efforts have been made to convert such residual oils into producer gas. Another reason which has influenced this work is the present industrial unrest as reflected in the high prices of coal and freight, which it is alleged has brought about the position that a producer gas made from oil can, under certain conditions, compete in price with producer gas from coal, and can much more successfully compete in price with town gas. As a matter of fact, the author himself, in the paper, did not stress this latter point; and it was left to various speakers in the discussion, who spoke highly of the "Hackol" process, to emphasize it. Under the influence of this favourable criticism, however, Mr. Hackford dealt with it a little more in detail in the course of the reply to the discussion.

Having experimented with furnaces of various types, which have formed the subject of early patent applications, in order to ascertain why these were not so completely successful as might be desired, Mr. Hackford has evolved a generator which relies upon the heat of partial combustion to provide sufficient heat to carry on the cracking process indefinitely. This generator obviates the use of baffles and external heating devices which are more or less common in other types of apparatus designed to develop gas from heavy oils. In this way it has been found that the composition of the gas is maintained constant, as also is the temperature, while the drawback of previous apparatus due to the deposition of coke or asphaltum is also avoided. Gases from 155 to 190 B.Th.U. per c.ft. are generated in this apparatus; and an important feature is that the plant is capable of adjusting itself to the load without material reduction in efficiency, which, according to the type of oil used, has been found to vary between 80 and 93 p.ct.

In the course of the discussion,

Mr. G. W. Anderson said that, while admiring the ingenuity of the work done by the author, it would be interesting to know why so many people who might be expected to use producer gas preferred town gas. Moreover, it was difficult to see why such a round-about process as the author's should be adopted when fuel oil in itself was such an excellent means of obtaining power by direct burning in boilers, engines, or furnaces. Another point which should not be overlooked was the national aspect of purchasing foreign oils for the purpose, when they had at hand in this country so many fuels available for power purposes.

Mr. W. Hesketh said that one of the drawbacks of the ordinary producer gas plant was the large amount of space which it occupied, and he looked to the author's process to overcome this difficulty because an apparatus measuring about 12 in. in diameter by 18 in. long was capable of an hourly production of 5000 c.ft. of gas of a calorific value of 150 B.Th.U. An ordinary producer plant using solid fuel would occupy, for this output, a space of 20 ft. long by 15 ft. wide.

Mr. Koopman, who has been associated with the author more on the commercial side, said that it was possible to produce gas by this process and to sell it at from 2¼d. to 3¼d. per therm, against 6d. to 1s. per therm for ordinary town gas.

Mr. W. J. A. Butterfield suggested that it would be interesting to have some comparative figures of outputs and sizes of plant using the author's process and ordinary producer gas plant.

Mr. Hackford, replying to the discussion, said it was possible to sell this gas at one-third the price of town gas, and at 66 p.ct. less than producer gas, with coal at 24s. per ton. A plant to generate 50,000 c.ft. of gas per hour occupied a space 36 in. long by 18 in. internal diameter, while the subsidiary apparatus would take a space of about 4 ft. square. As the reason why many people who wish to use producer gas to-day, but who used town gas, was that they had not the space to instal the ordinary producer gas plant, he looked for his process to appeal to these people. Commercial plants were now being constructed; and he hoped to have the opportunity of putting forward results from them in due course.

"The Cost of Freight Transport by Railway."—The object of this book, which has been written by Mr. F. W. Rogerson, is to examine the elements of railway operating expenses, and to describe methods of procedure in the development of a cost accounting system, particularly in respect to the determination and application of overhead charges. In view of the activities of the Railway Rates Tribunal, the necessity for correct records of railway operations will be felt in the future to a greater degree than in the past; and reliable data, easily and correctly compiled, will be found of immense service to officials and others. The book is published at No. 27, Pembroke Place, Liverpool; price 4s. 4d. post free.

NDON AND SOUTHERN DISTRICT JUNIOR GAS ASSOCIATION.

Annual General Meeting.

ie Annual General Business Meeting of the Association was at the Westminster Technical Institute, S.W., on Friday, 8—Mr. Newton Booth (the President) in the chair.

Financial Statement.

ie Hon. Treasurer (Mr. A. Broadbent) submitted the ncial statement, remarking on the healthy condition of the ciation. They would be able to start the new session with edit balance greater by £10 than at the beginning of the ent year. They had every reason to be satisfied with this of affairs.

ie President proposed the adoption of the balance-sheet. motion was passed unanimously, after being seconded by J. K. Grant, of the South Suburban Gas Company.

Report of the President.

ie President then reported as follows on the working of Association during the past year:

ie Council are pleased again to be able to report a most essful session. You have heard from the Treasurer's state- t that there is a small addition to the credit balance carried ard, and that the Association is in a sound financial posi-

As regards membership, the total number of members at date of the last annual general meeting was 295; and we admitted during the year 22 members. Unfortunately, ever, we have had a rather large loss of membership by gnation, &c.; the total number being 21, leaving us with a ent subscribing membership of 296.

ith regard to the programme for the session, we have again fortunate in securing high-class lectures and papers for our tings, and in having the opportunity of visiting a number orks. On the two short paper evenings, we arranged for papers only, as it was found that there was difficulty in pressing three papers into one evening. The result justified decision; and the evenings were very successful, especially n one remembers that the authors of the papers were mem- who had not previously contributed in this direction to our sactions. The pictorial lecture on the building of the Lea ge gasholder, given by Mr. D. Cleave Cross, was a very yable and most instructive event, as were also the lectures n by Dr. Hartley, Mr. Randall, and Mr. Dean Chandler. thanks are due to all these gentlemen who contributed to proceedings in this way.

ie Association have also been welcomed again at the enham and the Beckton Gas-Works, at the Kingsland Road er Works, and at two works where gas is not the chief est—the East Greenwich Generating Station and the Royal nal. The Council feel that it is in the best interests of the ciation occasionally to visit such works.

ie Council have with regret to inform the members of the gnation of the Hon. Secretary, Mr. Leonard Lacey, and the stant Hon. Secretary, Mr. W. H. Noble. Mr. Lacey has the office for two years with credit to himself and distinc- to the Association, and is relinquishing the position on unt of his more onerous duties in other directions. The ncil deeply appreciate his sterling worth and the services he rendered to them and the Association. Mr. Noble is about eek fresh fields in another hemisphere. His services are ly appreciated; and we thank him heartily for them. At ame time our best wishes will go with him when he leaves Mr. J. H. Goldsmith has kindly consented to take up the es of Hon. Secretary; and the Council trust he will receive whole-hearted support of all the members. It is expected nd a successor to Mr. Noble in Mr. A. Tennant, of the ydon Company.

o far we have been dealing with purely domestic matters; we have other interests. This year we had the honour of ing the Joint Council Meeting of the Junior Gas Associations ondon, at which your President took the chair. The princi- subject discussed was the Education Scheme; and the meet- had the advantage of the presence of Mr. Walter Hole. Junior Council expressed strongly the view that something e was needed than the group courses which had been put ard as the commencement of a course of studies leading o the Institution Diploma, and that it was necessary to with those men who, while requiring instruction in one or subjects, yet, by reason of age or capacity, lack the ability rofit by comprehensive group courses. The point made has its due effect. Our liaison with the Southern Association as Engineers and Managers has been maintained.

'e have still another meeting this session—our summer to Cambridge on June 20. The Council trust that there be a good attendance of members and their ladies.

id now, if I may be permitted a little personal note, I would to say what an advantage it would be to members and to Association if larger numbers attended our meetings and part in the discussions. Not only does knowledge grow by g disseminated, but the advantage to members themselves—cially the younger ones—of the personal touch, and the tice they get of clothing their ideas in spoken words, is great.

In conclusion I would like to thank the officers and Council of the Association, and especially the Hon. Secretary, for the splendid way in which they have helped me during the year, and all members for their support.

Mr. W. R. Moger (Tottenham District Light, Heat, and Power Company) proposed, and Mr. W. E. Brown (Gas Light and Coke Company) seconded, the adoption of the report.

A hearty vote of thanks was passed to the retiring officers and Council for the work done by them during the past year.

Testimonials.

Mr. J. R. Gale (North Middlesex Gas Company) proposed that the following testimonials be presented.

Mr. W. Newton Booth.

This testimonial, presented to Mr. W. Newton Booth, Assoc.M.Inst. C.E., by the Council and Members of the London and Southern District Junior Gas Association, places on record their high appreciation of the services rendered by him during his term of office as President for the session 1924-25.

His wide technical experience, together with his unfailing tact and courtesy, have increased the prestige of the Association.

In expressing their thanks, members trust that he will for many years to come enjoy good health, and continue to render valuable service to the industry.

Mr. A. Broadbent.

This testimonial, presented to Mr. A. Broadbent, on the occasion of his vacating the position of Hon. Treasurer to fill the office of Senior Vice-President, is intended to convey to him the thanks of the officers and members of the London and Southern District Junior Gas Association for his long and devoted service in the former position during the years 1920-25.

They feel confident he will, in the positions he will hold during the next two sessions, continue to merit their appreciation and esteem.

Mr. Leonard Lacey.

This testimonial is presented by the Council and members of the London and Southern District Junior Gas Association to Mr. Leonard Lacey, Assoc.M.Inst.C.E., on the occasion of his retiring from the position of Hon. Secretary.

It is their desire thus to record their earnest appreciation of the sterling services rendered while occupying this most important office for the last two years.

His efforts have done much to enhance the reputation of the Association; and it is the wish of all that he may continue to find advancement in the industry and enjoy a full measure of good health.

Mr. W. H. Noble.

This testimonial is presented to Mr. W. H. Noble, who for the two sessions from 1923-25 has rendered unobtrusive but useful service to the Association as its first Assistant Hon. Secretary.

In making this presentation, the Council and members of the London and Southern District Junior Gas Association extend to him their sincere thanks, and best wishes for his success in the future.

Mr. W. H. Cosh (South Metropolitan Gas Company) seconded, saying that their voluntary duties were deserving of the highest praise.

Mr. Newton Booth, on behalf of the officers of the Association, thanked the members.

New Officers.

The election of the following office-bearers for the next session was announced:

President.—Mr. W. L. Westbrook, North Middlesex Gas Company.

Senior Vice-President.—Mr. A. Broadbent, Gas Light and Coke Company.

Junior Vice-President.—Mr. Leonard Lacey, Gas Light and Coke Company.

Hon. Treasurer.—Mr. H. G. F. Soar, Gas Light and Coke Company.

Hon. Secretary.—Mr. J. H. Goldsmith, South Suburban Gas Company.

Assistant Hon. Secretary.—Mr. A. Tennant, Croydon Gas Company.

Council for 1925-26.—Messrs. W. T. Kenshole, A. Tennant, H. W. Kerridge, F. S. Larkin, J. K. Grant, E. C. Le Jeune, and J. Hewett.

Small Trenching Machines.—An account has been given to the Illinois Utilities Convention by Mr. A. G. Ford, of the success of his Company—the Western United Gas and Electric Company, of Aurora, Ill.—in obtaining a gas man's trenching machine. That is to say, a machine that will dig mains, services, and pipelines, and do it fast and continuously at low cost. The work of uncovering pipe for reclamation must necessarily be done with a minimum of hand labour; for it is very easy to spend more money uncovering pipe than the pipe is worth. The small trencher makes it possible to uncover at a profit pipe that would otherwise have been left in the ground. Figuring on seven months' work, a table of costs for three machines shows 6·54 c. per foot of digging. This is calculating depreciation and interest on the basis of 28 miles of trench as the life-work of a machine. Mr. Ford, however, is of opinion that 40 miles of trench for the life of a machine would be nearer the fact; and by using this figure as a basis, the total cost per foot would be reduced to about 5·5 c.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Low C.V. Gas and the Unaccounted-for Percentage.

Sir,—I was very interested to read Mr. Keillor's letter in the "Journal" last week. Let me assure Mr. Keillor at the outset, however, that I have not rushed blindly into print without realizing that many would not agree with my remarks. My statements may appear ridiculous to him; probably he has been fortunate in controlling a works and distribution department that has been kept in excellent condition for a long period. It is obvious from my remarks that this was not the case at Newark; and my intention was to make it clear that a low-grade gas cannot be distributed everywhere under present conditions without the possibility of trouble.

Mr. Keillor states that a 500 B.Th.U. gas, if not properly purified, will cause meter troubles. I quite agree with him; but my point is: Given a 400 B.Th.U. gas and a 500 B.Th.U. gas, each with the same amount of impurities, the 400 B.Th.U. gas will cause trouble quicker than the 500 B.Th.U. gas. The protective influence of the oily hydrocarbons in the richer gas will do much towards protecting meters internally. Many of us experienced acute meter troubles during the war, when oil-washing. Mr. Keillor says the secret lies in the purity of one's gas. This is obvious.

I stated that it may be possible to distribute a low-grade gas successfully with dry meters, providing every trace of impurities is removed. I am very glad to hear of this case of successful practical experience. I still think, however, that before a low-grade gas can be distributed successfully all over the country, much preliminary work in the way of improving, purifying, and cleaning-out distribution systems will require to be undertaken in many cases, unless someone comes along with a new type of meter. After all, there has probably been less development in the dry meter than in any other type of gas apparatus.

In the published returns of the Gas Regulation Act, 55 undertakings have increased their declared calorific value, and 7 have reduced it, since obtaining their original Order. The tendency seems to favour the higher calorific value at present. Perhaps the time will arrive when legislation will decide for us (as it is unlikely we shall all agree otherwise) a standard calorific value, when one bone of contention in the gas industry will have been buried.

F. A. West,
Engineer and Manager.

Newark Gas Company,
May 14, 1925.

South Metropolitan Gas Bill.

Sir,—The result of the above Bill before a House of Commons Committee will introduce a new train of thought as to the future policy of the gas industry, particularly as applied to company undertakings.

The stabilization of the basic price for ten years, following on a period of five years, indicates that Parliament appreciates the necessity for protecting a great industry from periodical and frequent revisions, and that Parliament also appreciates that the interests of the public are best served by eliminating from investors a feeling of insecurity—a sure influence against obtaining the cheap capital so beneficial to gas companies and their consumers.

It seems to me that the Gas Regulation Act of 1920 requires some improvement in its formula whereby the capital expenditure is taken into consideration, and the introduction of a provision giving the Board of Trade power to stabilize standard prices over periods of five or ten years. Otherwise a possibility of frequent revision will undoubtedly influence gas companies to "mark time" and become sterile.

R. W. Edwards.

Aldershot Gas, Water, and District Lighting Company,

REGISTER OF PATENTS.

Purification of Gases.—No. 223,191.

Urbain, E., of Paris.

No. 7239; March 21, 1924. Convention date: Oct. 13, 1923.

In introducing this patent, Dr. Urbain shows, by general observation and detailed examples, the possibility of completely purifying distillation and numerous other gases by utilizing a series of apparatus filled with absorbent carbonaceous material; each apparatus being worked so as to fulfil certain specified conditions. He points out that the variations of temperature in the carbonaceous material may give very useful indications to regulate the working conditions. The claims show the combination of steps which constitute his process; and we reproduce them *in extenso*.

1. The purification of gases obtained by the distillation of fuel and the recovery therefrom of valuable products, by bringing such gases, after they have been freed from tarry matters, into contact with absorbent carbonaceous materials or other solid absorbent substances having similar properties in a series of vessels, so as to remove: First the sulphuretted hydrogen in the state of free sulphur by oxidation; secondly, the ammonia in the state of ammonium sulphite by causing it to react in the presence of carbonaceous material with water vapour and sulphurous acid; thirdly, the condensable hydrocarbons and cyanogen compounds; and lastly, if desired, the carbonic acid; and subsequently extracting the absorbed products by any known method.

2. In the process claimed in Claim 1 the absorption of ammonia as gas instead of its precipitation as ammonium sulphite, as an alternative step in the said process and the subsequent removal of the absorbed compounds from the carbonaceous material.

3. The process of purifying gases obtained by the distillation of fuel and of recovering valuable products therefrom, substantially as described.

4. Distillation gases when purified by the process described as claimed.

Mantles for Upright Burners.—No. 224,850.

Gumperz, A., of Berlin-Schoneberg, and Meyer, A., of Berlin-Charlottenburg.

No. 2281; Jan. 28, 1924. Convention date: Nov. 15, 1923.

This invention is for a self-shaping upright incandescent mantle, the patentees claiming "a non-incinerated self-shaped upright incandescent mantle, for use with upright burners, provided at the base with a ring of metal or ceramic or any other suitable material, by means of which the mantle is placed on the burner head, so preventing the mantle from slipping down the burner head, and having the top-end a loop by which it is hung on the fork of the burner."

Alternately, the mantle is secured direct upon the burner head with wire ribbon, or asbestos thread.

Low-Temperature Distillation.—No. 225,513.

Kohlenscheidungs G.m.b.H., of Berlin.

No. 19,145; Aug. 12, 1924. Convention date: Nov. 28, 1923.

Introducing their invention for a low-temperature process, the patentees say that in the course of laboratory experiments they was established that with careless and sudden heating of the coal the yield of original tar became greater and the quality of the semi-coke better. If, for instance, Essen coal was distilled in the usual manner by gradually heating it to a temperature varying between 500° and 550° C., from 9 to 9·5 p.ct. of tar free from water was obtained. If, however, the apparatus was heated to this temperature prior to being filled with the coal, whereby the latter reached very quickly the low distilling temperature, and if the heating was carefully increased as much as 11·3 p.ct. of tar was obtained from the same material, the additional amount consisting principally of heavy oils. In addition thereto the semi-coke recovered was considerably firmer and much less porous, as was proved in the course of a most careful examination.

Further researches proved, in addition to a greater yield of hydrocarbons and a better semi-coke, that numerous difficulties accompanying the older processes are overcome or lessened—for instance the caking and swelling of the coal, the crumbling away of a large proportion so as to form dust, and so forth.

According to the invention, however, the new process consists in the fact that the material, which is not preheated at all or is only preheated to a slight extent, is suddenly subjected to a temperature which is much above normal distilling temperature—for instance 500° C.—so that the material itself is raised as quickly as possible to the distilling temperature, and that after reaching this temperature it is immediately removed out of reach of the high temperature in order to undergo an after-treatment at the normal distilling temperature.

The main feature consists in the rapid raising of the heat to the distilling temperature by using a degree of heat essentially above 500° C. For this reason, any preheating must not be carried to a degree at which it promotes, by the expulsion of water and the like, the effect of the quick subsequent heating according to the invention. The further treatment of the material at the distilling temperature serves chiefly to expel the last traces of the original tar, &c., and particularly to improve the quality of the semi-coke. With the process, say the patentees, it is of importance that, in order to work within low-temperature limits, the heating of the coal be not carried too far by leaving it too long in the high-temperature zone. The zone in which the coal must remain for a short period only will,

distance, be at about 700° C., and be increased to such a degree only as is absolutely necessary for effecting the rapid heating of the material.

It is pointed out that, in addition to the advantages mentioned, the amount of the material passing through the apparatus is considerably increased, since the speed of working is much greater than before. The patentees suggest that "rapid distillation at low temperatures" properly describes the distinctive feature of the invention.

Experiments have had the further surprising result of showing that the use of higher temperatures than the usual distillation temperature—for instance, 500° C.—is very advantageous not only for the treatment of the sticking coal but also for improving the quality of the distillates. Consequently the yield, especially of light oils, is increased if the hydrocarbons, immediately after their expulsion are passed through a hot zone—for example, through the first zone of the distilling apparatus, which, according to the invention, has been raised to a temperature of 700° C.

Preparation for Repairing Retorts, &c. No. 231,650.

SELLARS, B. C., of Droylsden.

No. 6176; March 11, 1924.

The patentee claims, for the repair of furnaces, retorts, &c., a mixture of dried silicate of soda with alumina, asbestos, fireclay, ganister, or barytes. The powdered mixture may be stored without ill effects, and is prepared for use by the addition of water.

Gas Ovens.—No. 231,664.

LIGGINS, J. W., of Accrington.

No. 7777; March 27, 1924.

In order to prevent the excessive ingress of cold air into an oven, the patentee claims the fitting of a plate, shaped so that a portion lies above the level of the burners and a portion below each burner; gaps being left for the passage of secondary air.

Lighting Control Apparatus.—No. 231,943.

KING, W. E., and THE GAS METER CO., LTD., both of Kingsland Road, E. 2.

No. 869; Jan. 11, 1924.

This invention is for a modification of the firm's well-known automatic lighting mechanism, wherein a train of clockwork, serving to operate the gas tap, is released and locked by means of a trip or stop.

The object of the invention is to simplify its working as applied to variable illumination, such as shop lighting.

The claims are for the inclusion of a mutilated toothed wheel which is partially rotated at intervals automatically so as to bring the teeth thereon into engagement or to bring them out of engagement with teeth on the fly pinion or similar part; and a circular disc, preferably of flexible material, a portion or portions of the periphery of which project so as to engage and temporarily lock the fly pinion in accordance with the desired predetermined sequence.

Valves for Purifiers, &c.—No. 232,012.

DEMPSTER, R., & SONS, LTD., HORSFALL, J. E., and LUMB, H., all of Elland.

No. 6756; March 17, 1924.

The object of this invention is to introduce a simpler valve arrangement than that covered by specification No. 211,269 [see "JOURNAL" for March 26, 1924, p. 791], and one which will reduce the number of valves required for performing the different operations.

The new design will enable the various operations to be performed by movement of a single control member for each valve, one of which is preferably situated at each end of each individual purifier.

Rotary tubular valves are employed in place of disc valves, and are mounted in casings and control ports or passages which lead to upper and lower portions of each purifier. Adjacent casings are placed in communication with one another by an intermediately arranged passage, and the lower end of each valve and casing communicates with a main inlet, or a main outlet pipe. Each valve is closed at its upper end and is keyed or otherwise fixed on a spindle which projects through the top of the valve casing and constitutes the single control member referred to.

Fig. 1 is a vertical section showing two adjacent casings connected by an intermediately arranged passage; and fig. 2 is a section taken on line 2—2 of fig. 1.

FIG. 1.

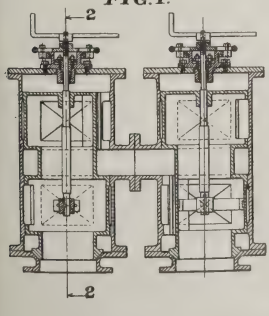

FIG. 2.

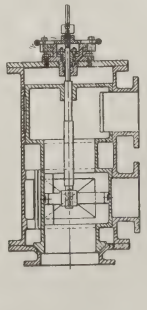


Rotary Purifier Valve.—R. Dempster & Sons, Ltd.

Prepayment Mechanism.—No. 232,016.

DOUGALL, J., of Chiswick, W. 4.

No. 6955; March 18, 1924.

This invention is for a safety device applicable to the type of prepayment meter mechanism described in specification No. 214,077 [see "JOURNAL" for May 21, 1924, p. 541].

Inserted between the external operating handle and the coin carrier, it consists of a shutter rigidly attached to the operating handle and co-operating with the coin carrier in such a manner that after insertion of a coin the operating handle has a certain amount of free movement in the driving direction before motion is imparted to the coin carrier, such free movement being sufficient to cause the shutter to obstruct the slot in the price-changing disc before driving contact is established between the operating handle and the coin carrier. The shutter itself forms the driving means for the coin carrier.

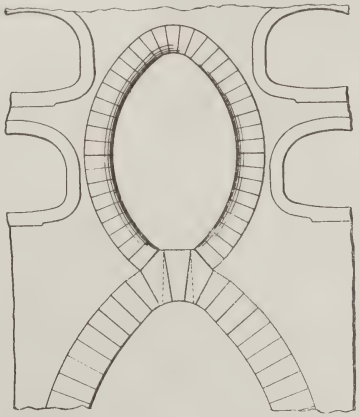
The invention also provides that the driving edge of the shutter and/or the edge of the price-changing disc towards which the coin is driven is or are chamfered in such a manner as to facilitate entrance of the coin into the coin carrier on rotation of the operating handle.

Retort Settings.—No. 232,357.

TOOGOOD, H. J., and DEMPSTER, R., & SONS, LTD., both of Elland.

No. 2510; Jan. 31, 1924.

According to this invention, which relates the regenerator furnaces of retort settings, the abutments on the producer arch for the combustion chamber arches are above or outside the normal contour of the producer arch, and the combustion chamber arches are made in the form of complete ellipses. This construction might seem to be disadvantageous in practice, as it would block the view of the producer gas nostrils from the inspection plugs; but in order to avoid this the keystones of both the producer arch and the superimposed series of combustion arches are combined (the nostrils coming between the combustion chamber arches). This construction gives the combined advantages of added strength of the completed elliptical arches, increased stability of the producer arch, the ability to withstand the indeterminate side-strains due to the increased temperature and use of silica, and withal the full visibility of the nostrils is maintained.



Producer and Combustion Arches.—R. Dempster & Sons, Ltd.

Furthermore, the construction enables the elliptical combustion chamber arches to be designed as complete ellipses of the fullest major and minor axes permitted by the particular grouping of the retorts, and with rounded or bull-nose arch bricks; such ellipses being designed of such shape as to accommodate the active flame of combustion (or inner cone of flame) issuing from the nostrils, with the very minimum of impinging of flame—to the advantage of the life of the refractories and evenness of carbonizing temperatures.

The shape of the keystone brick and the adjacent crown bricks are clearly shown in the drawing which we reproduce. The dotted lines indicate a nostril between adjacent combustion chamber arches.

Prepayment Mechanism.—No. 232,401.

FOX, T., and ROBINSON, S., both of Liverpool.

No. 8393; April 3, 1924.

Patent of Addition to No. 180,406, of Feb. 17, 1921.

This invention relates to the type of prepayment device claimed in specification No. 180,406 [see "JOURNAL" for July 5, 1922, p. 39].

Therein, the handle is adapted to pivot in a plane at right angles to the face of a guard disc acting as coin carrier. It is additionally

provided with a locking member and a guard plate, so that when the coin slot of the price-changing disc and the coin carrier coincide, the spindle is locked against rotation by the locking member or alternatively covered by the external guard.

The object of the present invention is to prevent access through the coin slots in their coincident position to the quantity wheel actuated by the coin. A pivotal slot-covering plate is arranged internally of the guard disc and is adapted to be locked in position by the locking member of the handle to cover the slot, and to be forced out of the covering position by the coin when forced into the coin carrier by rotation of the handle in a plane at right angles to the face of the price-changing disc.

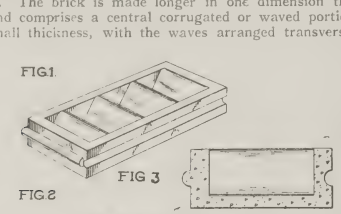
By this construction the coin, when inserted, cannot be pressed fully home by the hand, but must be forced to engage with the quantity wheel by the rotation of the handle.

Muffle Furnaces.—No. 232,480.

Gibbons Bros., Ltd., and Marle, M. V., both of Dudley.

No. 19,863; Aug. 22, 1924.

This invention has for its object the provision of an improved brick or unit for use in constructing the muffle or inner walls of a furnace chamber. The brick is made longer in one dimension than in the other, and comprises a central corrugated or waved portion of relatively small thickness, with the waves arranged transversely of the



Brick for Muffle Construction.—Gibbons Bros.

brick, and a peripheral portion of a width sufficient to contain the corrugations. Tongues or grooves for engagement with adjacent bricks are provided on all four of the outer edges of the peripheral portion, and these tongues and grooves are of shallow dimensions in comparison with the width of the other edges. Preferably, the thickness or depth of the peripheral portion is less than its width—*i.e.*, less than the over-all thickness of the brick.

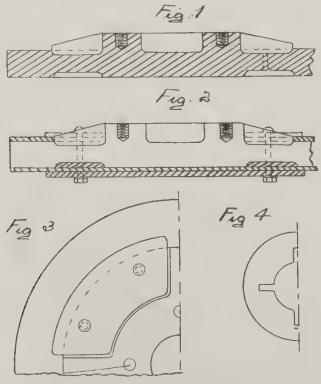
Fig. 1 is a perspective view of a brick, fig. 2 is a sectional view, and fig. 3 a transverse section.

Gas-Tight Disc Valves —No. 232,514.

Dempster, R. & J., Ltd., of Manchester, and Hill, W., of Stalybridge.

No. 27,637; Nov. 19, 1924.

The object of this invention, for purifiers, &c., is to enable leather facings to be suitable for making disc valves gas-tight; and in carrying out the invention, the patentees make use of prepared leather, having found that leather sufficiently impregnated with ordinary codliver oil is admirable for the purpose. In practice, they find that soaking the leather in the oil for about three days, when the oil is at ordinary atmospheric temperature, is sufficient.



Leather-Faced Disc Valve.—R. & J. Dempster, Ltd.

The application of the principle is clearly seen in the drawings we reproduce. Fig. 1 shows the metal disc without facings, while in fig. 2 are seen an upper and lower leather held in position by metal clamps and bolts. The upper clamps are four in number and segmented in shape, so as to clear the webs necessary for strengthening the disc; and the upper leather must be shaped for the same reason. They are shown in figs. 3 and 4 respectively.

PARLIAMENTARY INTELLIGENCE

HOUSE OF LORDS.

Forfar Gas Order Confirmation Bill.

A Bill to confirm a Provisional Order relating to Forfar gas wa presented last week by Lord Balfour of Burleigh, read the first, second and third time, and sent to the Commons.

HOUSE OF COMMONS.

Progress of Bills.

Bill reported, with amendments: South Metropolitan Gas.

The petition deposited by the Brighton and Hove General Gas Com pany against the New Shoreham Harbour Bill has been withdrawn.

The Forfar Gas Order Confirmation Bill was brought from th House of Lords, read the first time, and passed for third reading.

The Kilmarnock Gas and Water Provisional Order Bill has bee read a second time, and committed.

Statutory Gas Companies (Electricity Supply Powers) Bill.

This Bill, promoted by Mr. Clarry, was considered on the 14th inst read the third time, and passed.

Scientific Research.

Replying to Mr. H. Williams last Friday, Mr. Guinness stated tha a sum of £4,045,500 had been provided in the 1925-26 estimates fo scientific research of all kinds.

Gas Regulation Act.

A copy was presented of a draft of a Special Order proposed to b made by the Board of Trade under section 10 of the Act, on th application of the Haverfordwest Corporation.

The draft Special Orders for the Altrincham Gas Company and th Stockton-on-Tees Corporation have been approved, on the motion o Sir Burton Chadwick.

MIDDLESEX COUNTY COUNCIL BILL.

Petition by the Brentford Gas Company.

This Bill was under consideration last week by a Committee of the House of Commons, presided over by Colonel Wheeler. Its object is to confer further powers upon the Middlesex County Council and the Metropolitan Electric Tramways, Ltd., in reference to their light railways and tramways, and to enable the Council to make street improvements and tramways. The Brentford Gas Company, whose area of supply includes a large part of the county, petitioned against the Bill because, under the powers sought, lands and property of the Company might be compulsorily acquired, and their mains, pipes and apparatus might be altered and interfered with. Therefore, if the powers in the Bill were granted, it was asked that provision should be made for fully protecting the Company's property, rights and interests.

Though the Company were represented by Counsel (Mr. Ralph Bury), and Mr. A. A. Johnston (General Manager) and other officials were present in the room, the matter was not dealt with by the Committee. Negotiations are proceeding between the Council and the Company; and it is hoped that an agreement will be arrived at before the Bill reaches the House of Lords.

SOUTH METROPOLITAN GAS BILL.

Thursday, May 7

(*Concluded from p.* 475.)

At the conclusion of Dr. Carpenter's evidence, he was asked by a member of the Committee what his opinion was with regard to a long-dated provision for revision. His reply was that a period of 10 or 15 years would give him reasonable time in which to develop his undertaking—a certain security of tenure. It was pointed out by Mr. M'Millan, however, that an opportunity for revision would be presented when the Company next came to Parliament, and certainly 10 or 15 years would not elapse before they did this.

Mr. *Frank Jones* (Vice-President of the South Metropolitan Gas Company, Chairman of the Wandsworth, Wimbledon, and Epsom District Gas Company, and a Director of other gas companies) gave evidence. He pointed out that, under the Gas Regulation Act. the standard price was fixed by adding to the pre-war standard price (which was fixed by Parliament) an amount which would cover the increased costs of production, beyond the control of the Company, since 1914. If the Gas Regulation Act principle were applied to the South Metropolitan Company, however, which had its standard price abolished in 1920, that principle would be applied not to the pre-war price, but to a price fixed in 1920; and the latter figure did not cover the costs of the Company. This was proved by the fact that, subsequently, the price of gas had been increased beyond the basic price. It would be a very serious thing if at any time any persons could go to the Board of Trade and say that they thought a certain principle ought to be applied, and ask the Board to apply it. Discussing the question of the effect of the reduction of the Company's present basic price upon the workers, he pointed out that a great deal of industrial trouble had been caused by the fact that, when the workers had increased their output, their remuneration had been reduced. He said that the Parliamentary system of watching over the conduct of gas undertakings had worked quite well; and he challenged Counsel for the London County Council to put his finger on a single instance where the system advocated for the future had failed in the past.

In cross-examination, some discussion arose as to the working of he Gas Regulation Act. Mr. Abady's point was that, when arriving t a standard price under the Act, the starting point was the pre-ar standard price, which was fixed by Parliament, and the Board of rade fixed a new standard price which would leave the gas under-akers in the same position as before the war. A gas company could o to the Board of Trade at any time to have its standard price in-reased, if necessary; and he put it to witness that the Act afforded erfect elasticity, so as to prevent a company being prejudiced by lterations in economic conditions. Mr. Jones said it fell short of hat; and he pointed to the effect which regulations for revision at ny time had upon the investor, who never knew what his dividend ould be.

Mr. ABADY said that what the Company were asking for was hat the basic price should be fixed so high that it accommodated ny change in costs which might occur.

Witness said that he wanted the price fixed by Parliament.

As to the attitude of the gas industry at the time the Gas Regu-ation Act was being framed, it was suggested by Mr. Abady that the ndustry went to the Board of Trade, and asked that a Bill should e promoted, giving the Board power to revise charges, in contra-istinction to the previous practice of coming to Parliament. Also, e suggested that the National Gas Council had passed a resolution pproving the Bill. The reply of Mr. Jones was that the industry ad asked the Board of Trade to put them in a position to pay their ividends, and to get them out of the then existing impossible position. n 1919 gas companies had the right to appeal to Parliament; but at present, when local authorities asked for a revision of price by the Board of Trade, the companies could not appeal to Parliament.

Sir *Herbert Hamblin* (President of the Institute of Bankers, and Deputy Chairman of Barclay's Bank) said that in May, 1920, the p.ct. stock of the South Metropolitan Company had stood at £55 or £100, but before the war the value was £112. At present the Company's basic stock stood at £95. It was important that stocks of this character should be stable, because the investor in this class of stock was, as a rule, of a conservative type. As to the reason for he high value of the stock before the war, he said it was the fact hat the Company had enjoyed good credit, and was efficiently managed, which had probably induced many investors to take up the stock. The standard price had not been interfered with for many years; and on that basis the stock had attained a very desirable position on the market. If the basic price were to be overhauled at requent intervals, in accordance with changes in economic conditions, he stock would certainly be affected. The carrying of a fairly wide margin between the selling price and basic price gave a feeling of confidence to investors, and induced them to buy stock on a 5 p.ct. basis, with a faint hope that they might get more. Undoubtedly, those who advised investors looked at the basic price; and the continuance of the basic price was an element in the stability of the investment. Therefore, it should not be interfered with lightly, and should only be overhauled when there was an extreme divergence which rendered it an unfair price. Cheap capital enabled cheap gas to be supplied.

Mr. ABADY, cross-examining, pointed out that when the stock of the Company had stood at £55, in 1920, the dividend was restricted to 3 p.ct., because the Company were working under the Temporary Increase of Charges Act. The present figure of £95, however, was on the basis of a 5 p.ct. dividend.

COUNSEL asked the witness whether, if the basic price were reduced to a point at which the Company would be able to pay the dividend paid last year, and still leave a reasonable margin, the price of the stock would be affected materially.

Witness replied that it would not be affected materially, but the alteration would have an effect, because this was one of the factors considered when recommending a particular stock.

Mr. M'MILLAN, re-examining, said they were not concerned at the moment with the effect of one alteration of the basic price, but the effect of frequent alterations.

Witness agreed.

Following a request by the Chairman, the promoters promised to give information with regard to neighbouring gas companies with stock corresponding as nearly as possible to the stock of the South Metropolitan Company, in order that the Committee might see how the investing public regarded the stock of this Company as compared with that of other companies.

Mr. *F. I. Pitman* (Messrs. Rowe & Pitman, Stockbrokers) also gave evidence with regard to the stock of the Company, and emphasized the necessity for an adequate margin between the selling price and basic price. If, after the South Metropolitan Company's scheme had been working for five years, a clause were imposed upon them providing for the revision of the basic price at any time, it would produce a very bad impression in the mind of the investor, because it would appear to him that Parliament, for some reason, had thought fit to pull the Company up.

Mr. *William Cash*, F.C.A. (of Messrs. Cash, Stone, & Co., Chartered Accountants, and Chairman of a number of gas companies, Vice-President of the National Gas Council, &c.) said that the undoubted tendency of revision under the Gas Regulation Act provisions was to sterilize the position of gas companies. They were deprived of any advantage which would have arisen out of economies or growth of business if there had been no war. He was not complaining of the way in which the Board of Trade had carried out their duties, because he personally believed they were fair and reasonable; but the difficulty lay in the application of the formula in the Act. It was not an advantage to a company to have its price liable to revision continually. Such facts as this had to be stated in a prospectus; and the investor, who did not understand these things precisely, was left in doubt as to what sort of dividend he might get. Dealing with the present rise in costs, he said he doubted whether the increase of ¾d. per therm which had been made by the Company recently in the selling price of gas was really sufficient; but the Company were notorious for endeavouring to sell gas at the lowest possible price, which policy was the right one.

Mr. Cash then handed-in a statement showing the results of revisions of charges of gas companies under the Gas Regulation Act. These companies were the Gas Light and Coke Company, and the Commercial, Eastbourne, Newcastle, Walker and Wallsend, Brighton, Wandsworth, Portsea Island, Brentford, and Tottenham Companies. All these had had the standard prices, granted originally under the Act, reduced recently; and the table showed that in no case was the present standard price below 11d.

The following table was then handed-in to show what would be the present standard price of the South Metropolitan Company if the Gas Regulation Act had been applied:

Comparison of 1913 *costs with those for* 1924 *as per the printed accounts for those years, with adjustments for changes since December,* 1924 *showing increase of* 1913 *standard price by reference to increased costs.*

	1913.			1924.	
		£			£
1. Working expenditure		1,970,060	..		4,111,845
Less—					
2. Rent of stoves, meters, &c.	£254,296		..	£406,736	
3. Residuals	667,553		..	1,244,986	
4. Sundry receipts	2,970		..	4,712	
5. Co-partnership bonus	52,348		..	66,074	
		977,167	..		1,722,508
6.		992,893	..		2,389,337
7. *Add* net interest		67,718	..		119,667
8.		£1,060,611	..		£2,509,004
		d.			d.
9. Cost per therm		3·402			6·933
				d.	
10. Increased cost to Dec. 31, 1924				3·531	
11. Increase in wages from Jan. 1, 1925 (£40,000)				·110	
12. Increase in net cost of coal since Jan. 1, 1925				·287	
13. Savings in costs due to improved working results				·338	
14. Cost of extra 1 p.ct. standard dividend granted by Parliament in 1920				·182	
15. Total increased costs				4·448	
16. Pre-war standard price of 3s. 1d. per 1000 c.ft. = per therm				7·400	
				11·848d.	

Mr. ABADY, examining Mr. Cash's table, pointed out that the pre-war standard dividend of the Company was 4 p.ct., and not 5 p.ct., and that if the pre-war standard price were expressed in terms of a 5 p.ct. dividend it would have been equivalent to 5·9d. per therm, instead of 7·4d. If the basic price which entitled the shareholders to the same dividend to-day was 11d. per therm, the increase above the pre-war standard would amount to 5·1d. per therm. This was an increase of nearly 100 p.ct.

Mr. *Cash* did not agree with this way of putting it. If Counsel wanted to say that the standard price in 1914 was 5·9d., and not 7·4d., then there would have to be added the increased cost between 1914 and 1919, which was about 5d., giving a figure of 10·9d., which was very near 11d.

Mr. *H. T. Manley* (an Employee-Director of the South Metropolitan Company), in evidence, said that the workers fully understood the principles of co-partnership, and were fully alive to the fact that under the present system the consumer obtained a better distribution of profits than under the sliding-scale. The scheme had had a very good effect upon the attitude of the men towards the Company. There were 7775 co-partnership owners of stock, holding capital to the extent of £540,000; and since 1920 there had been strenuous and continuous efforts on the part of the men to keep-down the price of gas by means of hard work, as well as by skilful and intelligent work. The workers appreciated the fact that they had a statutory right to their benefit under the present scheme. The effect of reducing the basic price would be disastrous for all parties concerned. It would remove the workers' sense of security. They were keen on investing their savings in the Company; and if there was a possibility of the basic price being reduced, they would ask themselves seriously whether they would not do better to invest their savings elsewhere.

The Committee adjourned until Friday.

Friday, May 8.

Sir *William Plender* (Messrs. Deloitte, Plender, Griffiths, & Co., Chartered Accountants) said that he had advised the Company with regard to the provisions of the Act of 1920. The basic price of 11d. did not represent the exact equivalent, on the thermal basis, of the pre-existing standard price, but was separately arrived at. Dealing with the importance of an adequate margin between the selling price and the basic price, he said that costs of production were at present on the up grade, and wages were rising. An increase in rates of wages was granted as from Jan. 1, 1925, which was estimated to cost the Company £40,000 per annum, or 0·11d. per therm. Further, the net cost of coal was increasing, in spite of a reduction in the gross cost. This increase for 1925 was estimated at 0·287d. per therm, so that, together with the increased cost of wages, the increase would be 0·397d. per therm. In 1924 the amount by which the cost of gas to the consumer was less than 11d. per therm was £1,136,633, equivalent to 3·140d. per therm, so that the increased costs would reduce the latter figure to 2·743d. per therm. Further claims for increased wages in the gas industry, however, had been submitted. From an announcement in "The Times" for April 30, the men's claims were for an increased wage of 2s. per day, payment at time-and-a-quarter for night duty, and two weeks' annual holiday with pay. The effect of the increase of 2s. a day was equivalent to about two-thirds of a

penny per therm. Whether the increase would be granted or not, he did not know; but he mentioned it as a possible contingency which would reflect itself in the increased cost of gas. In view of the varying conditions since 1920, he did not think there had been at any time an excessive margin between the basic price and the selling price. In considering what was an adequate margin to allow, they had to take long views. The purpose of the fixation of the basic price was to enable the Company to proceed with a measure of assurance in making their arrangements for business, and as affecting their financial position in the market. Allowance had to be made for the fact that at present there was not the same stability as before the war. In the present period the margin should certainly not be less than before the war. Between 1920 and 1921 the net cost of coal had risen by the equivalent of 2d. per therm; and in 1922 the net cost of coal was 1d. per therm over 1920. In further justification of the maintenance of the basic price of 11d., he referred to a period of 30 years prior to the war, with a view to ascertaining what the margin was between the standard price and the price charged by the Company for gas supplied. He had found that, with perhaps one exception (1901), the margin between the two prices was in each year proportionately greater than the margin now existing. At present the selling price was 2¼d. per therm, or 20·5 p.ct., below the basic price. In 1914 the amount charged was 28·4 p.ct. below the standard price; and in each of the years 1910 to 1913 it was 29·7 p.ct. below the standard.

A table was submitted which demonstrated that, since the Act of 1920 became operative, the prices charged to the consumers had, with the exception of two abnormal half-years, been below the basic price. During 1923 and 1924 they were appreciably less. The consumers had received benefits far in excess of their share, as measured by the amounts distributed to the co-partners and stockholders; the dividends paid had been moderate; and the percentage of increase since the war was very much below that of Government or Trustee stocks. The percentage margin between the prices charged and the basic price had been no higher since 1920 than for many years before the war, when no alteration in the then standard price was suggested or attempted. The margin now prevailing was only fair and reasonable, in order to preserve a balance for emergencies, which even recent experience had proved to be a necessity.

Mr. Abady, cross-examining, said that, if 1924 were compared with a previous year under this scheme, and there had been an increase in the sale of gas owing to the number of consumers having increased, and the selling price had been maintained at the same level, while the benefit to the individual consumer would be the same, the benefit to the shareholders would be increased, because the amount saved to the consumers would be expressed in terms of a larger number of therms sold. Therefore, the shareholder would have his share increased without the price to the consumer being reduced. Under the sliding-scale, a reduction of 1d. in the price of gas would entitle the shareholder to one increment of dividend; and the amount that a shareholder could take would be limited by the amount of his shares. The inference he wanted to draw was that, with a basic price, there was less incentive to reduce the selling price of gas than there would be under the sliding-scale, because, by a mere increase in sales, the shareholder could divide a larger amount.

Sir *William Plender* said that, whatever the margin might be, the Directors would always reduce the price to the lowest possible figure. Their main interest was the consumer; and, so far as he knew, this had never been questioned during the last five years.

Mr. Abady replied that he did not think it would be questioned in respect of any gas company. Continuing, Counsel pointed out that the Company had a reserve fund and a special purposes fund; the latter being designed to meet expenses incurred by reason of circumstances which due care and management could not have prevented. Therefore, if it were said that the margin between the selling price and basic price was necessary in order to meet contingencies, it must be remembered at the same time that there were other resources.

Witness observed that the question of drawing on the funds depended entirely on the present conditions; it was a question of what was the best financial policy. He admitted that at present the margin was considerably more than that in 1920, when the question of contingencies was considered.

Re-examined with regard to the point that the shareholders benefited by a mere increase in sales, witness said that a low selling price stimulated sales, and the increased sales might, therefore, be the result of the Company's policy of selling at the lowest possible price.

This closed the case for the Gas Company.

Mr. Abady, addressing the Committee on behalf of the London County Council, said it had been stated by the Company that they had come to Parliament in 1920, and had made a special case before a Parliamentary Committee, and had urged this case on their distinguished record—a record which was to be regarded as different from the records of other companies. This, generally, was the note which had been sustained throughout the present proceedings; and it was suggested that this record justified a special treatment being accorded to the Company. If the clause which the London County Council asked for were not inserted in the Bill, the South Metropolitan Gas Company would be the only one in the Kingdom, selling gas by the therm, which would not be subject to revision in the manner provided by the general law. This was a strong position to take. The County Council had no complaint to make as to the manner in which the South Metropolitan Gas Company had dealt with the public in the past, or had approached the County Council with regard to matters concerning them. There was no rancour. The Council were merely pursuing their public duty. When the Company came to Parliament in 1920 they were suffering from something from which all sliding-scale companies were suffering. It had been said that the general Act did not apply with absolute uniformity to all gas undertakings in the provinces and in London. He maintained that it did; and it applied to the South Metropolitan Company itself with respect to the quality of the gas supplied. Therefore, it applied absolute uniformity to every undertaking in the United Kingdom which was selling gas by the therm, including the South Metropolitan Company, except, in the latter case, in regard to the one matter of the method of fixing the price. Dealing with the present position under the Gas Regulation Act of 1920 as regards revision of price, Counsel said it was idle to suggest that to-day there was nobody at the Board of Trade capable of dealing with the revision of prices. The Board of Trade had already, under the Gas Regulation Act, revised the prices of hundreds of companies, some of them in the downward direction. The procedure was that schedules of costs were prepared, as before the Act, and at the time of revision, and the necessary adjustments were made. On this ground, therefore, there was no reason why the South Metropolitan Gas Company should not come within the same procedure. Moreover, it was not accurate to say, as had been claimed on behalf of the Company, that its Act of 1920 introduced for the first time a system of charging for gas on a heat basis. As a matter of fact, at the time the Company's Act was passed, there were about a hundred companies which had received Parliamentary sanction to supply on the basis of calorific value; and the bulk of the gas in the London district was supplied on a heating basis at that time. It was true that up to 1920 the obligation still remained upon the gas companies to charge by the thousand cubic feet, but each cubic foot had to contain a prescribed number of thermal units. He contended, therefore, that the South Metropolitan Gas Company could not claim to be pioneers as regards selling gas on a heat basis. Dealing with the Company's Act of 1920, Counsel agreed that there was a material alteration of the Company's position under that Act, to which attention should be drawn. As things stood before the Act, the shareholders were never sure of the 4 p.ct. on the shares; but under the Act the Company were given a minimum of 5 p.ct., no matter how high the charge was, in order to pay this dividend. It was here where the public interest came in, and why the London County Council were so concerned. It was stated that there was only a difference of 2½d. between the basic price and the selling price; but it must be remembered that 1d. per therm represented 5d. per 1000 c.ft., so that there was a margin at present between the basic price and the selling price of 1s. 0½d. per 1000 c.ft. The view of the London County Council was that, unless the basic price and the selling price or costs were in close consonance, there might just as well be no basic price at all, so far as it provided an inducement to the Company to reduce the price of gas. Nobody would suggest that the Directors of the Company were not perfectly honest straightforward business men, who at all times were actuated by a desire to do the best for the consumer; but the point was that Parliament, in the Gas Regulation Act of 1920, had laid down a procedure for the revision of prices of all gas undertakings in the country. Why should not the South Metropolitan Gas Company come within this general Act? The present Committee had no evidence upon which they could fix a new price. All the Committee had got was that Dr. Carpenter had agreed that costs to-day were lower than they were in 1920; and Mr. Cash had said the same thing. Thus the Committee were unable to say that the present figure of 11d. was or was not sufficient. The London County Council were fighting for a principle—viz., revision by the Board of Trade. If the Council's clause was not inserted, he would ask that a clause be inserted which would bring the Company to Parliament at intervals, so that revisions could be made at the instance of either the Company or the Council. A period of ten years had been suggested by one of the members of the Committee. It was not in the public interest that this Company should be left absolutely without any provision for revision of its price; and the same would be said of any company, however good or capable its management.

At the conclusion of Mr. Abady's address, the Chairman gave the decision of the Committee which was recorded in last week's "Journal"—namely, that the basic rate of 11d. was justified at the present time, but that an opportunity should be given for revision, if the circumstances warranted it, in 1935.

Wednesday, May 13.

Sir Lynden Macassey, K.C., for the promoters, submitted the following clause, which, he said, gave effect to the Committee's decision as regards the basic price and revision. [The preamble of the Bill generally was found proved at the previous sitting of the Committee.]

(1) The Company shall, not later than in the session 1935, promote a Bill in Parliament giving an opportunity for the amount of the basic price prescribed by the South Metropolitan Gas Act of 1920 to be revised by such Bill.

(2) The London County Council and the Council of any Metropolitan Borough or Urban District within or partly within the limits of supply of the Company shall (subject to their complying with any relevant statutory requirements and Standing Orders of Parliament) be entitled to be heard before the Committee, to which any Bill promoted for the purpose aforesaid shall be referred, as to whether a new basic price should be substituted by such Bill for the basic price prescribed by the said Act of 1920.

Sir Lynden Macassey said that, by the terms of the clause, there would be no question as to the *locus* of the local authorities being challenged. They would be heard as to whether a new basic price should be substituted for the existing price of 11d. The clause had been submitted to the London County Council; but they had made no comments upon it, so he could only assume that they were keeping the way open for opposition in the next House, on principle.

The Chairman said the Committee would accept the clause, although they would like Sir Ernest Moon, K.C., the Speaker's Counsel, to examine it. If he proposed to make any modification, it would be communicated to the parties.

The Parliamentary Committee of the London County Council, in a report presented for confirmation at the meeting of the Council yesterday, stated that the clause which has been inserted in the Company's Bill does not meet with the objections of the Council; and they have therefore given instructions for a petition against the Bill to be deposited in the House of Lords.

MISCELLANEOUS NEWS.

IMPERIAL CONTINENTAL GAS ASSOCIATION.

The Ordinary General Meeting of the Association was held last Wednesday, at the Cannon Street Hotel, E.C.—Sir Charles J. Jessel, Bart., in the chair.

The Secretary (Mr. F. H. James) read the notice convening the meeting.

The Register of Proprietors.

The Chairman: I now beg to move that the Common Seal be affixed to the Register of Proprietors.

The seal having been affixed,

The Chairman proceeded: I beg to move:

That the interim dividend at the rate of 5 p.ct., less tax, paid in respect of the half-year ended June 30, 1924, be hereby confirmed.

The Deputy-Chairman (Col. H. LeRoy-Lewis, C.B., C.M.G., D.S.O.) seconded the motion, which was unanimously agreed to.

The Chairman then called upon the Secretary to read the Auditors' certificate on the accounts submitted; and this having been done,

The Chairman proposed:

That the accounts for the year 1924 and the scheme prepared in accordance with the Companies' Clauses Consolidation Act, 1845, showing the profit available for the purposes of dividend, which the proprietors have before them in the form of the Profit and Loss Appropriation Acount, be taken as read.

Loss by Death.

The Chairman: Ladies and gentlemen, I regret to have to begin my remarks to you this afternoon by referring to the gap that occurred in our Directorial ranks through the sudden death on June 26 last, of Mr. Hugh Goodwin Newton. Mr. Newton's family had long been connected with the Association. His father had been an Auditor from the early Sixties, was elected a Director in 1867, and was made Chairman of the Association during my first year of office in 1895. He served as Chairman until 1903, and died in 1906. He was succeeded by Mr. Hugh Newton, who therefore served the Association for no less than eighteen years. He was a useful Director, and we greatly deplore his very sudden death. In his place we have, as you see, elected Mr. George Jessel. I hope you will pardon the partiality of a parent if I say that we could not have done better. No doubt some of you will have read the interesting document referring to our centenary which was sent out to you with the accounts, and will have noticed that in the early years of the Association my son's great-great-grandfather was a Director, at the same time as his son Sir Francis Goldsmid). So history, after a certain number of years, has repeated itself.

The Accounts.

Now I think I cannot do better than I have done in previous years —that is, take you through the accounts that are in your hands. On the right hand side of the profit and loss account, the first item is "net profit from stations, £174,943 10s. 9d." I should like to dwell on that item for a few minutes, because I have received two letters from proprietors who are somewhat anxious as to the future. They notice the item of "Revenue proportion of German compromise. £179,783 14s. 3d.;" and they have deducted this from the balance of profit on the left-hand side. The two gentlemen to whom I refer then proceed to ask: "How on earth are you going to continue in the future to pay 10 p.ct. dividend, if you only show about £50,000 profit"? I should like to draw your attention to the fact that on the debit side you will see "Income-tax and corporation profits tax. £119,103 13s. 4d." Of course that includes the income-tax on the revenue proportion of the German compromise, as well as the corporation tax, which will not appear in the accounts again. The combined amount is about £50,000. Then again, you will see an item "Exchange and contingency account, £14,000," which is by way of reserve. It is also to be remembered that the practice of this Association has always been, when we have had money to spare, to write down everything to what I may call absolutely ground-level. That is to say that, if there is any doubt in our minds, we write it down to the very smallest sum we can think of. The reason we do that is that we have to amortize all our assets abroad. It saves the amortization fund in years which may not be so prosperous. I do not for one moment wish to suggest that there is any magic about the 10 p.ct. dividend. No promises have ever been made by me, or by anybody else, that we are going to pay 10 p.ct. for the rest of our life as the Imperial Continental Gas Association; but what I think runs in the minds of these shareholders is that this Association has always been of a conservative character, and therefore we are not likely to pay a dividend of 10 p.ct. unless it is fairly assured for the future. Well, I can tell you that, as far as I can see, in spite of the many difficulties—particularly difficulties connected with exchange—which are obtaining abroad, I do not contemplate any trouble in maintaining this rate, at all events for the current year.

Dividends on Investments.

"Dividends on investments, interest, discounts, &c., £125,168 11s. 3d.," you will see are lower than last year by £13,215. The reason for this is that 1923 included a little extra dividend that were received from the now-absorbed Lille Electricity Company. From this source we received in 1923 £6000 odd, which was for dividend during the war period. Then again, you must remember that we exchanged considerable amounts of Conversion Loan against debenture stock; and you will see the benefit of this on the other side, where, of course, the debenture stock interest is correspondingly decreased. I do not think I need dwell further upon that.

The German Compromise.

The next thing I have to talk to you about is the revenue proportion of the German compromise. You will remember that we received on previous occasions, of the £1,600,000 which we were to get, all except £387,487 10s., which sum we received on May 1 of this year. Deducting the Clearing Office commission of £39,000, we have to account for £1,561,000; and the apportionment of this net sum is as follows:

Capital accretion	£1,081,561	
Revenue	479,439	

Now before I go further into this, I think it will be as well to refer to another letter which I received from a shareholder. When in July last year we received a sum of money through the Clearing Office, this shareholder wrote to the office of the Association and asked why the money was not at once distributed. Well, the answer to this is that, under section 120 of the Companies' Clauses Consolidation Act we are not allowed to divide anything unless we submit to our shareholders a scheme of profits. Ten years ago, when I was a hot-headed youth of about 55, and when I was not even restrained by a Secretary who was then an impetuous young man of very nearly 60 years [Laughter], I proposed to you on two occasions to pass a dividend of 4½ p.ct.—that was during the war, and the money was very gratefully received by the shareholders. I then one day was approached by a shareholder, who almost threatened to prosecute me for having committed a crime against the Act of Parliament to which I have referred. Thereupon I had recourse to our legal adviser, who told me he was perfectly sure that I had committed a crime; and with a prospect of long lingering in gaol, I consulted him as to how I should get out of the difficulty. He said that the only way was to obtain an Act of Parliament condoning the offence. Well, we did get an Act of Parliament condoning this offence; but, of course, I was not going to expose my crime, and so we wrapped it up with other things which we thought necessary—such as having only one meeting in the year, &c. I think we are to be congratulated —myself, and the Secretary, and Messrs. Dyson (our Parliamentary Agents) on securing an Act of Parliament which has very much facilitated the distribution of the various sums which we received. To go on with my story, of the revenue proportion, £359,582 17s 10d. has been taken into general revenue up to Dec. 31, 1924, and utilized mainly for the general purposes of the business—*e.g.*, financing the considerable capital outlay at the stations. Towards the end of 1924, the sum of £142,922 was remitted out of these funds to cover part of the call on the Association's subscription to the new issue of shares of the Cie. Continentale du Gaz, Paris—a Company which offers good prospects of a profitable employment of the funds invested. This Company paid a dividend at the rate of 10 p.ct. in 1924, and shows every sign of maintaining that rate this year. The centenary bonus dividend, which, if approved by you to-day, will be paid on May 26, is made possible by the German compromise revenue. The balance on revenue account of £119,856 2s. 2d. will appear in the accounts of the present year, as the accounts for 1924 had been closed some time before it was definitely known if, and when, the final payment would be received. It must be borne in mind that the final revenue proportions will suffer deduction of income-tax at the rate in force at present. The capital accretion has been dealt with as follows:

Special dividend June 15, 1923, 12 p.ct. . .	£237,113	7	8
,, ,, May 20, 1924, 10 p.ct. . .	£197,600	0	0
Proposed ,, ,, May 26, 1925, 19½ p.ct. . .	£385,320	0	0
41½ p.ct. . .	£820,033	7	8

Well, now, you would like to know, perhaps, what we intend to do with the balance. Some time ago—I will not say that I wrote an article—I inspired a paragraph that appeared in "The Times" with reference to what was going to be done; and I then was bold enough to say you were going to get 50 p.ct. as capital accretion; so this leaves another 8½ p.ct., or £107,960, to come next year—making a total of £987,993 7s. 8d. dealt with in this way, and leaving a balance to be carried forward for capital purposes of the business generally (and we urgently require it in the business) of £93,567 12s. 4d.

A Claim for Interest.

Then I have something else to tell you of a pleasant nature. You will recollect that, at the last meeting, I informed you of the rejection by the Mixed Arbitral Tribunal of our claim for interest upon the German compromise owing to the lengthy delay in settlement. This year I am able to give you more satisfactory news. The British Clearing Office, who had urged this course upon us, and who have always been zealous in guarding the interests of the British claimants, felt that the principle at stake was too great to permit this rejection to be accepted without an attempt on their part to obtain what they considered, and what I consider, was only justice. They therefore entered into negotiations with the German authorities, and on Sept. 13 1924, an agreement in respect of the payment of interest was concluded. The Association is therefore the lucky recipient of a net sum of £62,332 19s. 6d. (after deduction of income-tax and commission) in respect of the claim rejected by the Mixed Arbitral Tribunal. [Applause.] Of course, any question about the disposal of this or any like sum will have to be left over to another year, therefore I do not think I need worry you any more on this subject now.

Profit and Loss Account.

Now I will return to the profit and loss account. You will see on the left-hand side Expenses in London, &c., show a reduction of more than £2000; and then comes the item of income-tax and corporation profits tax, which I have already referred to. Interest on debenture stock is, of course, down by £3156, and balances with the smaller amount of interest received on Conversion Loan stock on the other side. The general amortization account is up by £15,439. I shall just have to say a word about that, because one of the shareholders (he happens to be an eminent K.C.) wrote to me on the subject, and said: "I do not see why you should have any amortization fund at

all. Your capital is represented on the other side by investments; why make an amortization fund?" Now, having been responsible for a great many years for the financial policy pursued by the Board, I am rather touchy on the question of that policy; and I should like to explain once and for all that the policy of the Association for long past has remained the same—namely, that any asset which is in our hands should be kept going at a constant value. The moment it ceases to have that value, it should be written-down. Therefore if we have, as you know we have, leaseholds abroad, we must be prepared to replace these leaseholds in one way or another. This has been the fixed policy for a number of years; and I hope you will never think it necessary to question for a moment whether the capital is intact, or expect us to take into consideration what premium or discount our stock stands at. The amount appearing for legal charges is accounted for by a French case which arose when we had French stations of our own. This case goes back as far as 1906. They are even slower there than in England on the subject of taxation; for they have taken eighteen years in France to settle this question. We had at all events the interest on the money for this long period; and then when we had to pay it away, it was in francs, which were at that time 82 to the pound. Though the amount looked large in francs, when reduced to sterling it was not a matter of great consideration. The balance of profit for the year is £230,628.

The Balance-Sheet.

With reference to the assets side of the balance-sheet, the item of "Works, mains, &c.," is £174,049 up, principally on account of the Brussels electricity extensions. Freehold land forming the sites of works is very different—£99,000, against £152,000. What has happened is that we had made a reserve for depreciation on account of this freehold land, but it appeared on the other side under sundry creditors; and we have thought it better to show what the real position is. Freehold land abroad has, in the currency of the respective countries, increased in value naturally, but it has not increased in value as much as the currency has gone down in terms of sterling. Therefore when we are presenting to you accounts which are rendered in sterling, we thought it better to have this item clearly set forth. There is an increase of £71,000 in stocks at stations. This applies really to all categories; but I am sorry to say there is one disquieting feature—and that is the large stock of coke at Antwerp, which we cannot dispose of. When I last heard of it, it was 22,000 tons; but I am glad to say it is not growing. This is a matter which, I think, affects nearly every gas company all over the world. There is an increase of cash; we happen to want a good deal more money abroad at the moment. The large reduction under sundry debtors is owing to the inclusion last year of £188,000 on account of the German compromise, which we had already received months before the meeting. You cannot, therefore, really compare the item with this year. We also received a sum of money from the Cie. Continentale du Gaz. I need not dwell at this point on the item "German Compromise." Loans to foreign gas and electricity companies are smaller, because the Central Gas Company of Hungary repaid some of their loan in 1924, and wiped off the balance this year. The decrease in freehold property in London and abroad is also attributable to the same reasons that I have already set forth under Freehold Land. This, of course, deals with the property which is not actually the site of works—such as offices, and perhaps engineers' houses, and other places, and also our offices in London. The reserve fund investment is altered because we converted our 5 p.ct. War Loan into 4½ p.ct. Conversion Loan. Our pension fund shows no change. English, Colonial, and Indian securities are up by £181,181, because we have made a temporary investment of £200,000 in Treasury Bonds. It is money we shall probably have to deal with next year, when we pay you the final dividend on the German compromise. Next come foreign gas and electricity companies. Here there is an increase of a considerable sum, owing to the investment we have made in the Cie. Continentale du Gaz. They doubled their capital, and called up 25 p.ct., and also a premium of 50 frs. per share. This cost us £178,224. It may interest you to learn what the effect of the exchange is on this Association. In 1924 we had an interim dividend of 6 p.ct. on our holding in the Cie. Continentale du Gaz, which produced 2,589,840 frs., and this translated into sterling amounted to £34,198. In November and December of last year we invested, as I have said, in this Company a further 15,285,550 frs. (£178,224); and the interim dividend in April of this year, which was at the same rate of 6 p.ct., in spite of this additional £178,224 invested, produced only £35,750 (3,244,935 frs.), or about £1600 more than before we put this large further sum into the undertaking. The reason for this is very easily explained. When the dividend came over in 1924, the franc was worth 73 to the pound; whereas in 1925, it was about 20 frs. to the pound more. That will give you a very good illustration of what the depreciation of the franc means to an Association like this. As to the item of "miscellaneous foreign securities," on account of the Belgian law we had slightly to increase our holding there by buying Treasury Bonds, because of their Accident Insurance Laws. On the other side, I have already explained about the debenture stock. Regarding the item of "Sundry stockholders, amounts unclaimed, account reduction of capital," there are a few people who are kind enough still to leave their money with us, instead of taking it. Nothing else calls for mention until we reach the general amortization fund. That is up by £56,836. As I have shown you, there is £59,491 to be put into it, and a few thousands to be taken out on account of the liquidation of Bruex, which I referred to on the last occasion. Sundry creditors are up, because £33,748 more is due to contractors. The item "Commissioners of Inland Revenue" is beyond regret. The renewals fund was drawn upon on account of the liquidation of Bruex, and also to a small extent because of plant that had been scrapped.

Profit and Loss Balance.

Lastly we come to the profit and loss balance, after deduction of interim dividend, available for appropriation. The balance brought from last account was £45,951 6s., and the profit for the year 1924 £230,628 4s. 1d.—making a total of £276,579 10s. 1d. Deducting the 5 p.ct. interim dividend paid in November last, £76,570 12s. 9d., there is a balance available for appropriation of £200,008 17s. 4d. To pay the proposed 5 p.ct. final ordinary and 5 p.ct. centenary bonus dividends, an appropriation of £153,141 5s. 6d. will be required, leaving a carry forward of £46,867 11s. 10d.

The Work of the Staff.

I need not, of course, say that, as usual, I shall be very pleased to answer any questions that shareholders may wish to ask me; and I do not think I should sit down without referring again this year to the wonderful services which have been rendered to us by our staff both at home and abroad. I can only thank them, in the names of myself and of my colleagues, for the good work they have done. [Applause.] I would like to make a special reference to the work of Mr. J. G. Van Niftrik, the Manager at Flushing, the great value of which may be calculated from the fact that the increase in the gas consumption at his station represents an advance of 55 p.ct. as compared with 1913. Mr. Van Niftrik has now retired from the managership at Flushing owing to advancing years, and I am sure he will carry with him your good wishes. He had been with us 35 years, and had been the Association's Manager at Flushing since June, 1889. In accordance with the Association's practice he has been granted a pension. He has been succeeded by Mr. J. J. Van der Jagt, his chief assistant, who has been in the Association's service since November, 1908. There is one other matter to which I should like to allude while I am speaking, and that is the resolution which is going to be proposed later on by a proprietor who has given notice to that effect. The genesis of the motion is that I was approached indirectly by one of the largest proprietors—if not the largest proprietor—in this Association, and was asked whether I did not wish the usual course to be pursued of rewarding the Directors with something on the occasion of the centenary of the Association. Probably this is news to my colleagues; but I do not mind saying now that I declined, on behalf of myself and the Board, without consulting them, to have any such proposal made. At the same time, I pointed out another direction in which something might be done. Of course, we have full scope with regard to our existing staff and their wives. We have a liberal pension fund, and we help them when they are sick and sorry; but there are other occasions you can very easily imagine that arise. For instance there might be a man with a moderate salary who perhaps had not "cut his coat according to his cloth," and had a somewhat larger family than he ought to have had considering his means. Such a man might find that a little assistance towards the education of his youngest daughter or his eldest son would be of great value to him; but we, having no precedent, and no wish, to go outside our usual scheme of gratuities or pensions for sickness, have naturally to refuse to assist in these cases. Therefore I said: "If you wish to do anything to mark appreciation of the services of the Directors and the staff during this long period of a hundred years, I think that if a proposal were made to place a modest sum"—I did not wish to frighten proprietors by mentioning too large an amount—"at the disposal of the Board for this purpose, it would be practically certain to receive the assent of the shareholders." ["Hear, hear."]

The Dividends.

I have now to move:

> That the sum of £388,903 8s. 1d. received from the realization of the German assets, being an accretion to capital which has been realized and turned into money, be dealt with as profit and applied in payment of a special dividend for the year 1924, at the rate of 19½ p.ct. per annum on the nominal amount of the issued capital stock of the Association, such dividend to be paid on the 26th of May, 1925, upon the holdings of capital stock as registered in the books of the Association on the 27th of April, 1925.

The Deputy-Chairman: I beg to second that.

The motion was put to the meeting, and carried unanimously, without discussion.

The Chairman: I next have to move:

> That upon the holdings of capital stock as registered in the books of the Association on the 27th of April, 1925, there be also paid on the 26th of May, 1925, less income-tax at 4s. 6d. in the pound—
>
> (*a*) A final ordinary dividend for the year ended the 31st of December, 1924, at the rate of 5 p.ct. (actual), making with the interim dividend of 5 p.ct. (actual) paid in November, 1924, a dividend of 10 p.ct. for the year.
>
> (*b*) A special bonus dividend, in celebration of the Association's centenary, at the rate of 5 p.ct. (actual),

Leaving £46,867 11s. 10d. to be carried forward to the next account.

The Deputy-Chairman seconded this, and it was agreed to.

The Chairman: Now I have to move:

> That the accounts, together with the scheme for the appropriation of the profits, which have been submitted, be received, adopted, and entered upon the minutes.

The Deputy-Chairman seconded this, and it was carried.

A Memorial of Gratitude.

Mr. H. E. West: I have much pleasure in moving the next resolution. The usual notice has been given, and I have reason to believe that it will prove acceptable to the shareholders. You will appreciate the Chairman's unselfishness in deciding that, if any money were voted, it should be devoted to the staff, and not to the Board. Few companies are spared to celebrate their centenaries, and the record of this Association is, I believe, unique. This record is the result of an able and far-seeing policy on the part of the Board, helped by a capable and loyal staff. I beg to move:

> That a sum of £2000 be placed at the disposal of the Board to be utilized for the permanent endowment of such philanthropic object as they may select having as its primary object the extension of assistance to deserving cases occurring among the families of employees of the Association; the said endowment

to be an abiding memorial of the proprietors' gratitude to the Directors, past and present, for the valuable services rendered by them to the Association during the period 1824 to 1924.

Sir Lucas Ralli: I have much pleasure in seconding that.

Mr. Fred. Tomkinson: I wish to support this resolution, and also to express my thanks for the extremely able speech we have had from the Chair. I think we owe a deep debt of gratitude to the Directors for the work they have done during the past year. My main object in rising, however, is to refer to the excellent booklet entitled "The Centenary of the Imperial Continental Gas Association" which was sent out with the report and accounts. It shows the very remarkable result of the hundred years' work; and I would like to thank the Board for giving us so charming a memento of the occasion.

The resolution was passed with acclamation.

Re-Elections.

The Chairman: I beg to move the re-election of the following Directors, who are all old and tried administrators of the Association. Col. H. LeRoy-Lewis, C.B., C.M.G., D.S.O.; Mr. R. W. Wilson; and the Rt. Hon. Sir Guy D. A. Fleetwood Wilson, G.C.I.E., K.C.B., K.C.M.G.

Mr. H. G. Palmer seconded the motion, which was unanimously agreed to.

Mr. C. F. Dendy Marshall, M.A., was re-elected an Auditor of the Association, on the proposition of Mr. Percy de Worms, seconded by Sir Lucas Ralli.

A vote of thanks to the Chairman and Directors, proposed by Mr. Tomkinson, was carried with applause, and suitably acknowledged by the Chairman.

Note.—It is of interest to record that at this meeting in the centenary year there were present three direct descendants of the original founders of the Association—*i.e.*, Mr. Harold Godfrey Palmer, Mr. George Jessel, M.C., and the Reverend Canon Attwood.

BRENTFORD GAS COMPANY'S STANDARD PRICE.

The Public Control Committee of the London County Council, reporting that the Board of Trade have issued an Order providing that, as from April 7, the standard price of the Brentford Gas Company is to be reduced from 17·8d. to 14d. per therm, point out that this decision is the mean of the Company's and the Council's estimates. The effect of the award on the authorized dividends payable by the Company is shown below:

—	"A" Consolidated Stock.	"B" Consolidated Stock.
Amount of stock	£992,045	£990,500
Standard rate of dividend	4 p.ct.	3½ p.ct.
Rate of dividend authorized and paid in 1914	£5 14s. p.ct.	£5 12s. 6d. p.ct.
Rate of dividend for 1924:		
Authorized	£8 p.ct.	£8 10s. p.ct.
Paid	£6 2s. p.ct.	£6 2s. 6d. p.ct.
Maximum rate of dividend payable under Board of Trade's award at present price of gas (9·8d. a therm)	£6 2s. p.ct.	£6 2s. 6d. p.ct.

It will, they add, be seen that the new standard price will allow the payment of dividends substantially greater than those authorized before the war, assuming that the actual price charged will remain at 9·8d. a therm. It must be remembered, however, that the shareholders are entitled to additional dividend in respect of their share of any savings effected by the Company by good management. If the Company's estimate of 0·36d. a therm as the equivalent of such savings is correct, the corresponding increase of dividend to which the shareholders are entitled in this respect may be put at 4s. p.ct. on the "A" stock and 5s. p.ct. on the "B" stock.

STAFFORD GAS UNDERTAKING.

The report of the Stafford Gas Committee for the year to March 31 shows a gross profit of £13,743, which leaves an available profit of £1175. The gas made amounted to 325 million c.ft.—a slight increase on the make for the previous year.

Alderman Young (Chairman of the Committee), in moving the adoption of the report, drew attention to the fact that the price of gas had been reduced on two occasions during the year. The low prices at present charged, he suggested, would assist in developing the town. The Committee and Council were to be congratulated on having such an asset in their well-managed undertaking. Since Mr. Poulson had been in charge, the results had been excellent, and improved as time went by.

Alderman Westhead seconded, and emphasized that more gas had been supplied to the consumers during the year, in consequence of the reduction in price.

Synthetic Ammonia.—The recent announcement of a guarantee of £2,000,000 under the Trades Facilities Act as new capital for Synthetic Ammonia and Nitrates, Ltd., indicates great expansion of the undertaking, set up at Billingham, near Stockton-on-Tees, by a subsidiary company of Messrs. Brunner, Mond, & Co., for making ammonia from atmospheric nitrogen. The works at Billingham will be extended to four or five times their present size; and the output, restricted at present to 120 tons of sulphate of ammonia per day, will approach 800 tons daily.

NOTTINGHAM GAS PROFITS.

£88,545 Last Year.

The annual report of the Nottingham Corporation Gas Committee for the period ended March 31 shows that the undertaking is enabled to contribute £25,000 in relief of municipal burdens.

In contrast with the record for remunerative results, which was established in 1923, when the profits totalled £181,367, and also in comparison with those of 1924, which aggregated £165,502, the amount now available is £88,545. But, as Sir Albert Ball (Chairman of the Committee) observed, in moving the adoption of the report by the Council, it is a cause for satisfaction that the undertaking has done so well in a period which has been beset with difficulties. He referred to the shrinkage of residual prices, the most salient example of which was that the income from tar products had gone down by £28,053.

The Committee's report, which was adopted, afforded much interesting information indicative of continued effective management. The income last year amounted to £645,204, and the expenditure to £556,659, leaving a balance of £88,545 to be carried to the profit and loss account. To this balance is added £3572, representing bank interest and interest on revenue account investment, together with £50,208 brought forward from last year. After charging interest on capital, contributions to sinking funds, and £15,000 for depreciation of mains, meters, and stoves, there remains an available balance of £62,441. The Committee, having decided to allocate £25,000 as a contribution in aid of the general district rate, recommended that the balance of £37,441 be carried forward. A considerable tonnage of coal has still to be taken under the contracts, and the prices payable thereon will, it is pointed out, have a material effect upon the accounts for next year. New contracts are being made for a limited tonnage at lower prices, but, even now, the Committee observe that gas coals are not purchasable on the same terms as other industrial coals; the lower prices for industrial fuels being due entirely to the general depression in trade. The average price paid for coal, 24s. 1·33d. per ton, showed an increase of 7·53d. per ton on the previous year. The average price paid for the year ended March, 1914, was 11s. 5·55d. per ton.

The Committee, for some considerable time past, have been of opinion that the period would arrive when abnormally high prices for coal, materials, and labour would coincide with a severe depression in the markets for residuals. Unfortunately this period has now arrived, and the Committee consider it necessary to inform the Council that an increase in the price of gas cannot be avoided if the present conditions continue for an extended period. However, having regard to the severe depression prevailing in industry, the Committee do not recommend any increase in the charges for gas, advising that the existing scale shall remain in operation for the time being, even if, in so doing, an actual trading loss is made.

The quantity of gas sold during the past year in Nottingham and district was 2,571,307,200 c.ft. (12,213,709 therms), compared with 2,560,574,300 c.ft. (12,162,728 therms) for the previous year—an increase of 10,732,900 c.ft. (50,981 therms). The quantity of gas sold per ton of coal carbonized was 12,704 c.ft. (60·3 therms), as compared with 13,128 c.ft. (62·3 therms) last year. The decrease is due to the extended use of local coals and a slight improvement of the calorific value of the gas supplied.

The following figures show the difference between present-day and pre-war costs in relation to the undertaking:

Year Ended	Gas Sold (C.Ft.).	Total Expenditure. £
March, 1925	2,571,307,200	556,660
March, 1914	2,251,302,700	250,995
Increase	320,004,500	305,665

It is pointed out by the Committee that the expenditure per million cubic feet of gas sold has therefore increased from £111 9s. 9d. for the year ended March, 1914, to £216 9s. 9d. for the year ended March last—an increase of 94 p.ct. The following are the comparable receipts for gas per 1000 c.ft. sold for the same periods:

	s. d.
March, 1925	3 5·30
March, 1914	2 5·17
an increase of	1 0·13, or 41·58 p.ct.

Mr. John Wilkinson's Report.

In his fourteenth annual report, Mr. John Wilkinson (the Engineer and Manager) affords the information that during the period under review 196,198 tons of coal and 133,723 gallons of oil were utilized in course of manufacturing:

	C.Ft.	Therms.
Coal gas	2,588,362,000	12,317,461
Water gas	81,843,000	390,016
Total	2,670,205,000	12,707,477

The gas unaccounted-for during the year was 98,897,800 c.ft. (493,768 therms), or 3·70 p.ct., as compared with 3·69 p.ct. for the previous year.

Montevideo Gas and Dry Dock Company, Ltd.—At the meeting next Wednesday (May 27) the Directors will report that, after providing for interest on debenture stock and other charges, and including £14,401 brought forward from the previous year, the balance at the credit of profit and loss available for dividend is £36,074. A dividend of 2 p.ct., free of income-tax, is recommended, making, with the interim distribution, a dividend of 4 p.ct., free of income-tax, for the year. This will leave a balance to be carried forward of £14,397. Compared with the previous year, the total sales of gas show an increase of 8½ p.ct. The extension of the manufacturing plant has been continued, and enlargement of many of the mains is in progress.

CITY AND GUILDS OF LONDON INSTITUTE.

The following questions were set in the City and Guilds of London Institute Examinations in the subjects named:

GAS-WORKS PRACTICE.

Grade I.

(Not more than eight questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. Sketch and describe the producer used for heating a regenerative setting of horizontal retorts. (45.)
2. Describe, with the aid of sketches, how the gas passes from the retort to the foul main. (45.)
3. Describe the operation of clinkering the producer of a retort setting. (35.)
4. Sketch and describe one form of apparatus for removing traces of tar from the gas after it leaves the condenser. (35.)
5. What impurities are present in the crude gas after it leaves the condenser, and how are they removed? (35.)
6. Give a sectional sketch of an oxide purifier, and explain the chemical action in the purifier and during the revivification of the oxide. (35.)
7. Describe an apparatus for ascertaining (*a*) the specific gravity, and (*b*) the calorific value, of coal gas. (35.)
8. Sketch and describe the apparatus used for making carburetted water gas. (35.)
9. Describe, with the aid of sketches, the following parts of a gas-holder: (*a*) Top curb, (*b*) vertical stays, (*c*) cup and dip, (*d*) bottom curb, (*e*) inlet and outlet pipes. (30.)
10. What is the function of the station governor? Explain its construction and working. (30.)

Final Examination.

(Not more than eight questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. Sketch a cross-section of a modern retort house equipped with regenerative retort settings, stoking machinery, and coal and coke handling plant, describing briefly the various apparatus used. (45.)
2. Sketch and describe a blue water gas plant fitted with waste-heat boiler. (35.)
3. Describe the method of starting-up a carburetted water gas plant from cold. (35.)
4. Discuss the probable composition of coal gas having a calorific value of 560 B.Th.U., and how it would be modified by the addition of 25 p.ct. of blue water gas. (45.)
5. Describe the construction and working of a sulphate of ammonia plant, making special mention of the working conditions of the saturator. (35.)
6. Describe the methods of sampling and testing the producer gas and waste gases of a regenerative retort setting. (35.)
7. Describe, with the aid of sketches, a modern coke breaking and screening plant. (35.)
8. Discuss briefly the test used for chemical control in a gas-works. (35.)
9. Prepare a skeleton specification for a tank 60 ft. diameter by 25 ft. deep, suitable for storing oil for the manufacture of carburetted water gas. (30.)
10. Describe the apparatus used for determining the composition of illuminating gas. (30.)

GAS SUPPLY PRACTICE.

Chief Examiner: Mr. H. Kendrick.

Grade I.

(Not more than eight questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. State fully the comparative advantages and disadvantages of cast iron, wrought iron, and steel for street mains and services. For what pressures is each most suitable? (30.)
2. Describe fully the operation of temporarily stopping a leakage in a 6-in. main. How would you deal permanently with a split main, a split socket, and a main broken completely round? Give sketches in each case. (35.)
3. (*a*) How does temperature and atmospheric pressure affect unaccounted-for gas? What other factors influence the volume of gas paid for, as compared with the volume of gas made. (30.)

or

(*b*) Describe and sketch the following: (i.) A ratchet stock, (ii.) an anti-pulsator, (iii.) a thermostat, (iv.) a gas-main expansion joint. (30.)

4. Sketch and describe an efficient street lamp governor. How may unsatisfactory governors affect the efficiency of inverted burners? (35.)
5. (*a*) What are the chief factors to be allowed for when fixing the diameter of pipes for internal fitting work? State the maximum allowable cubic feet of gas per hour, and the maximum length advisable in gas fitting work for $\frac{3}{8}$-in., $\frac{1}{2}$-in., $\frac{3}{4}$-in., and 1-in. lead, compo, and iron piping. (40.)

or

(*b*) How may very small leakages be shown in interior fitting work? Sketch in detail the apparatus you would use, and state how you would locate such a leakage in a confined space. (30.)

6. What appliances are required for the official testing of meters? State in general terms the regulations under which these tests are made. What are the limits of error allowed? (30.)
7. How would you prove that the pressure of gas at a meter outlet is adequate for the requirements of a particular consumer? What is the minimum pressure allowed by the Gas Regulation Act? Where should this be ascertained? Is this pressure adequate for the needs of the average consumer? If not, what pressure is desirable to ensure the best results for lighting and heating? (30.)
8. Sketch and describe the working and construction of a dry gas meter. What are the chief parts upon which the accuracy of registration depends, and the parts that affect the gas pressure if the meter is overworked? (40.)
9. (*a*) Why do oven burners sometimes "smother out"? Can this be prevented? What means would you employ for ascertaining whether the ventilation of the oven was deficient or excessive? (30.)

or

(*b*) Describe fully the cycle of operations in the cylinder of an "Otto" type gas engine. If a gas engine slowed down and finally stopped, how would you locate the fault or faults, and then remedy them? (40.)

10. (*a*) Explain with sketches the correct form of bunsen flame for (i.) a "C" burner, (ii.) an inverted burner, (iii.) a gas fire. What alterations, if any, would be necessary to maintain the same maximum efficiency when consuming horizontal straight coal gas, vertical gas, and mixed gases, each of 480 B.Th.U. calorific value? (40.)

or

(*b*) During the war, various devices were used in connection with the burners of cookers already installed, to overcome the tendency to light back. Describe and sketch two of these. How did they effect the desired object? Would they be useful in present circumstances, and, if so, why? (35.)

11. (*a*) A consumer complains that his gas fire does not give sufficient heat, and an objectionable smell is given off from the gas iron when first lighted. What are the probable causes and remedies for the complaints? (35.)

or

(*b*) Describe and sketch the operation of tapping and connecting a service pipe to a steel main. What precautions have to be taken to prevent damage to the main pipe during the work and after it is completed? (30.)

Final Examination.

(Not more than eight questions to be attempted. The maximum number of marks obtainable is affixed to each question.)

1. State in general terms the regulations governing the powers of authorized and unauthorized gas undertakings to break up dedicated and undedicated streets for the purpose of laying mains. (40.)
2. An 8-in. diameter main is increased in length from 1200 yards to 3600 yards. To what must the initial pressure of 2 in. be increased to ensure the same discharge of gas? Upon what formula is the answer based? (30.)
3. (*a*) Describe and sketch an apparatus for reinforcing the general supply of gas in a low-lying district where the consumption is mainly domestic. Is it necessary to work the plant continuously over the 24 hours? Sketch 24-hour charts of the booster outlet pressures for a mid-summer and a mid-winter day for an area as above stated. (35.)

or

(*b*) A railway company has demanded that gas undertakings on its system shall fix by-passes to meters supplying its goods yards and junctions, which are to be opened should the meters break down. Why is this undesirable from the gas undertakings' point of view? Could not the feared difficulty be met in a manner less open to objection? (40.)

4. (*a*) How do the regulations for testing meters differ under the Gas Regulation Act, 1920, and under the Sales of Gas Act, 1859? In what way are the new regulations to the advantage of the gas undertakings and the consumer? (30.)

or

(*b*) A bridge of 60 ft. span has been constructed over a river. The roadway is carried on box girders 3 ft. 6 in. deep and 6 ft. centre to centre; the floor being formed of reinforced concrete slabs, leaving 18 in. between the bed and the flags forming the footway. The roadway rises 1 in 10 to the bridge on both sides. Show in detail two methods by which you would carry a 24-in. diameter main across the bridge, and how you would provide for contraction and expansion. (40.)

5. (*a*) What precautions are necessary when fixing and adjusting pneumatic switches in order to ensure satisfactory results? Describe how you would carry out an installation in a cinema, and what provision you would make to prevent extinguishing of the by-passes. (30.)

or

(*b*) What does "co-efficient of friction" mean? What was Dr. Pole's constant? Is this correct? If not, state the variations for 2-in., 6-in., 12-in., and 24-in. diameter cast-iron mains. (35.)

6. (*a*) State the methods that you would adopt to revive (i.) a man who had been badly gassed by inhaling straight coal gas, and (ii.) a man who had been badly gassed by inhaling a mixed gas containing 30 p.ct. of water gas. (30.)

or

(*b*) Discuss the relative merits of compression of (i.) gas, (ii.) gas and air, (iii.) air only, in high-pressure lighting and furnace work. (30.)

7. (*a*) State what you know about bread and biscuit baking by gas. What are the relative costs for fuel and labour in a large and in a small installation when using gas and solid fuels? (40.)

or

(*b*) Sketch and describe a regenerative oven furnace for hardening, reheating, and annealing steel castings. State the average consumption of gas per cwt. of steel, and its economy in costs over solid fuel when used for annealing, exclusive of the fuel used for the primary heating of the furnaces. (35.)

8. (*a*) Sketch and describe a Spencer-Bonecourt boiler capable of evaporating 700 lbs. of steam per hour from 212° Fahr. How

does chimney draught affect the production of steam? What are the comparative costs of raising steam by this type of boiler and by Lancashire boilers, taking into consideration capital, fuel, labour costs, and repairs? (40.)

or

What are the advantages and disadvantages of flue pipes used in conjunction with gas cooking stoves?

Some recent tests of gas fires referred to during the Smoke Abatement Exhibition in Manchester last autumn showed the presence of carbon monoxide in the flue gases. Would this be dangerous to health? Discuss these statements. (35.)

The ordinary type of multiple nipple burner for street lighting a group of small mantles set in more or less circular form. Does ensure even lighting along and across a narrow street? Give a led sketch and description of a burner now on the market that improvement on this general design and lighting effect. (30.)

(*a*) State what you consider to be the chief advances in gas-fire construction during the past ten years, as shown by the designs submitted by the makers, and mention the causes which have led to the improvements enumerated. (35.)

or

What purposes do indicator diagrams serve in gas engine practice. Sketch such diagrams, and explain the effect on the respective curves of (i.) a choked exhaust pipe, (ii.) too small a supply of air, (iii.) the pre-ignition of the mixture. (35.)

(*a*) How may the variations of flame temperature be measured? State briefly a method of estimating radiant energy from a gas fire. (30.)

or

What proportion of light rays from an inverted burner are radiated above the horizontal; and how is this ascertained? What means are adopted in the construction of street lanterns for ensuring the greatest efficiency and evenness of lighting on the road surface? (30.)

LIGHTING OF LONDON SCHOOLS.

n the annual estimates for fuel, gas, electricity, and water, 3,050, and for building work not chargeable to capital account, 2,000, being submitted at last meek's meeting of the London nty Council, Mr. C. E. GIBBINGS moved that it be referred to the nce and Education Committees to consider and report as to the aration of a supplemental estimate of £1000 with a view to ring improved lighting at certain schools. In moving the amend-t, he drew attention to the inefficient lighting of some of the old ols in Southwark, and said that in certain rooms there were 16 burners that were put there 20 or 30 years ago. As a business osition it would be quite right for the Council to have these things ed, in order to give a much better light. In the lighting bill e it would save about 50 p.ct.

r. HERBERT MORRISON, seconding, thought the day was not far nt when no more gas lighting would be left in London schools. present lighting of schools was disgraceful, and had a bad effect the health of children, teachers, and other people using the ldings. The Council might be able to obtain very favourable s from municipal electricity undertakings for the installation of tricity in place of gas in the schools, if they could offer those rtakings an increased load for other purposes—such as electric vers.

rs. WILTON PHIPPS (the Chairman of the Education Committee) sed to accept the amendment, on the ground that the Committee sufficient money at their disposal to carry out any improvements ssary. She agreed that the lighting of some of the schools was bad. The question was under the consideration of the Buildings Committee; and she was very anxious that the illumination ld be improved. In the case of the old schools, she was afraid substitution of electricity for gas would be a slow process; but he new schools electricity would certainly be used.

he amendment was defeated by 69 votes to 28, and the estimate pted.

GAS SUPPLY IN SINGAPORE.

he report for 1924 of the Municipality of Singapore Gas Depart-t will be the last to bear the signature of Mr. J. P. Hallaway as Engineer; for he retired in February from the position, which had held for 23 years, and has been succeeded by Mr. F. Bedford, was appointed Assistant Gas Engineer in 1922. In Mr. Bedford Commissioners will, Mr. Hallaway says, "have a very experienced hard-working officer, who can be depended upon to further their rests and the development of the Gas Department."

he report shows that the quantity of gas manufactured in 1924 271,845,000 c.ft. (including 39,526,000 c.ft. of water gas), which pares with 267,970,000 c.ft. for 1923, an increase of 1·4 p.ct. the output, 30·8 p.ct. was used for public lighting. To private sumers 3·6 p.ct. more gas was sold than in 1923; and the number consumers increased by 105 during the year. The number of king, water heating, and other appliances fixed on hire grows sfactorily; and Mr. Hallaway is of opinion that the use of gas these purposes, as well as for industrial operations, will rapidly ease. The amount of gas accounted for was 12,801 c.ft. per ton coal, against 11,758 c.ft. for 1923. A very satisfactory reduction accomplished during the year in the proportion of unaccounted-gas; the figures being 10·7 p.ct. in 1923, and 7·5 p.ct. for 1924. When Mr. Hallaway took charge in 1902, the make of gas per ton was 44,659,000 c.ft.

The Bradford Corporation Gas Committee have allocated £10 for l prizes in connection with the usual "Fairy Gas" competition anized among school children by the "B.C.G.A."

THE SMOKE NUISANCE.

Dealing with the question of smoke and atmospheric pollution, a table is given in the report of the Medical Officer of Health for the City of London for 1924 showing the rainfall from January to December and the amounts of insoluble matter—tar, soot, and dust—found, also the soluble matter, together with the sulphates, ammonia, and chlorine in the volume collected. A comparison is made with Lambeth (Archbishop Park); and only in May and December did the solids at Lambeth exceed those in the City. It is pointed out that, in July only, the deposit registered as falling in the City amounted to 20·96 tons per square kilometre, which is equal (estimating the City as having an area of one square mile) to no less than about 53·6 tons. Of this mass of dirt, approximately 24·9 tons were soluble, and included the chemicals mentioned, and 28·7 tons were insoluble, and consisted of tar, carbon, and grit.

In addition a daily observation had been made at mid-day at the Guildhall of the purity of the air by a modern dry method, by which the suspended matter could be readily demonstrated. From Jan. 1 until Dec. 31 the amount of the impurity at noon had varied from half a milligramme to six milligrammes per cubic metre of air; this latter figure including times of fog.

Commenting on this, the Medical Officer adds: "For many years past it has been increasingly obvious that the use of electricity and gas for heating and cooking purposes is contributing to the diminution of the nuisance from smoke. The cost of electricity is still far too great for its general use, but I believe the substitution of gas for coal and coke in restaurants and business premises is practicable, and might be more generally adopted if the gas companies encouraged its greater use, possibly to their own profit, and certainly to the advantage of the populace, by arranging a special rate for the supply to premises of the class indicated. Were such special terms for gas as those suggested arranged, I am of opinion that the increased purity of our atmosphere, as would be observed by City workers, would be so marked that an agitation against the unnecessary use of common coal would result, and public opinion might even extend to statutory prohibition being enforced."

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *May* 18.

Pitch continues nominal at about 41s. to 42s. per ton.

Attention is now concentrated on tar for road work, and considerable quantities are being delivered.

Creosote is displaying a slightly firmer tendency at about 7d. to 7⅛d. per gallon net and naked at makers' works.

Solvent naphtha is in good demand and scarce at about 1s. 8d. to 1s. 9d. per gallon for 95-160 quality.

Pure benzole and pure tuluole are about 2s. per gallon.

Tar Products in the Provinces.

May 18.

The markets for tar products are practically unchanged.

In pitch there is little or no business now doing for prompt delivery. It is probable that the present spell of hot weather will definitely stop any further purchases being made for delivery this season, and it may be that it will result in some quantity sold for delivery this season being carried forward to next. As regards next season, some business has been done on the East Coast at 41s. a ton f.o.b., and in London at 41s. 6d. to 42s. Reports from the Continent are to the effect that considerable quantities of continental pitch have been sold for next season at prices which at to-day's rate of exchange certainly do not amount to more than 40s. f.o.b. England. Some business is reported to have been done on the Continent in British pitch at 42s. and 42s. 6d. a ton f.o.b.

Creosote oil is quiet in the absence of any foreign demand. It is known, however, that little or no business has been done for July-December. A considerable quantity has to be purchased, as stocks on this side are quite small. Present prices should be maintained, or even some improvement effected. In the meantime, small quantities have been sold at rather less than the figures which have been recently ruling.

White products are steady. As usual, there is a very good demand for benzole for motor purposes, while solvent naphtha is in increased demand owing to the activities of the rubber trade. Both crude carbolic and cresylic are neglected, while naphthalene is almost unsaleable.

The average values for gas-works products during last week were: Gas-works coal-tar, 27s. to 32s. Pitch, East Coast, 40s. 6d. to 41s. 6d. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s. Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8½d.; crude, 65 p.ct., at 120° C., 11d. to 1s. 1d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 7½d. to 1s. 8½d. Toluole, naked, North, 1s. 6½d. to 1s. 7½d., nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8½d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 5⅝d. to 6¼d.; salty, 5⅜d. to 6d.; Scotland, 5⅝d. to 5⅞d. Heavy oils, in bulk, North, 6½d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality, 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

Cape Town and District Gas Company.—At to-day's meeting of the Cape Town and District Gas Light and Coke Company, Ltd., satisfactory progress will be reported. A final dividend will be recommended on the ordinary shares of 4 p.ct., making 7 p.ct. for the year; and this will leave £3820 to be carried forward.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

Apart from a rather steadier position in Northumberland steams, there is little of interest to report from the Newcastle market. Durham coals are, if anything, rather weaker, and the demand shows no signs of improving. It is reported this week that unsold stocks in Germany amount to eight million tons, and pressure by some of the banks which are financing these enormous quantities is said to be causing many concerns to accept almost any price. With the concessions in railway rates recently granted to the German mines, therefore, the tendency is for competition against English exports to become more and more severe.

Some of the Northumberland collieries are well booked for a week or two ahead; but in Durham it is still generally a hand-to-mouth existence. Wear Specials and best-quality gas makers quote 19s. f.o.b.; but many brands are obtainable at considerably less than this, especially for loading terms which suit them. Seconds are nominally 17s. The demand for coking is negligible, and prices are 16s. 9d. to 17s. 3d., while best quality bunkers are hard to maintain at 17s. 6d. to 17s. 9d.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

Gas coals generally have been booked much earlier than usual this year. Several inquiries on the market are to be decided before the end of the month in respect of deliveries to commence at the beginning of August or September, so that it will be seen that the buyers are not prepared to wait until there may be an alteration in present-day conditions and prices before completing their purchases for next year. Prices as a rule show a reduction of 2s. to 3s. per ton as compared with last year.

The warmer weather has caused a reduction in the demand for household coal, and it is just possible that irregular working of collieries will result. If this is so, there will be a tendency for the price of industrial fuels, especially small hand slacks, to rise a little above the low figures that have prevailed for some months.

There is no change in the demand from the industrial coal consuming centres, although in the clothing trades it is anticipated that they will show better results during the next few months. The iron and steel trades, however, are still depressed.

The slump in shipping continues, although South Yorkshire hards are keeping firm in comparison with other grades. This undoubtedly will be the position for some weeks, as the Doncaster Races and the approaching Whitsuntide holidays will, as always, have a steadying effect on this particular grade.

Prices at Hull at the week end (f.o.b. usual shipping ports) were: South Yorkshire—Hards, Association, 20s. to 20s. 9d.; screened gas coal, 18s. 6d.; washed trebles, 20s.; washed doubles, 17s. 6d.; washed singles, 16s. to 16s. 6d.; washed smalls, 12s. 3d. to 12s. 6d.; unwashed doubles, 16s. 6d.; rough slack, 10s. 6d. to 12s.; and smithy peas, 19s. to 20s. West Yorkshire—Hartleys, 17s. to 18s.; screened gas coal, 18s.; washed trebles, 18s.; washed doubles, 16s. to 17s.; washed singles, 15s. 9d. to 16s. 3d.; washed smalls, 11s. 6d.; unwashed trebles, 17s. to 17s. 6d.; unwashed doubles, 13s. to 14s.; rough slack, 10s. 6d.; and coking smalls, 9s. Derbyshire and Notts—Top hards, 19s. 6d. to 20s.; washed trebles, 17s. to 19s.; washed doubles, 16s. 6d. to 17s.; washed singles, 15s. 3d. to 16s.; washed smalls, 11s. 6d. to 12s.; unwashed doubles, 14s. to 15s.; rough slack, 10s. 3d. to 10s. 9d. Yorks, Derbys, and Notts—Screened steam coal, 15s. to 17s.; gas coke, 21s. 6d. to 24s.; furnace coke, 15s. 6d. to 16s. 6d. per ton.

In Lancashire, industrial unscreened coal is 21s. at the pits, and the best qualities of Lancashire slack are from 15s. to 17s. per ton.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

A number of gas undertakings have already negotiated contracts for the new year's supplies. They are able to buy at 2s. to 3s. below the rates which have applied in the term now drawing to a close, the fall varying according to quality. Yorkshire gas coal, which was priced at 21s. to 22s. under the old contracts, is now selling at 18s. to 19s. The gas-works are not likely to be much better off, however, when against these savings is set the depreciation in coke and residuals, not to mention the acceptance of undelivered balances on the old high-priced contracts. Undertakings which have a considerable surplus of coke are now selling at 18s. to 20s. in order to rid themselves of the output, though in centres where the industrial demand is relatively heavy the price may run up to 24s. or 25s. There is no improvement whatever in the call for works fuel. Cannock Chase steams can be bought at 15s. at the pits.

The house coal trade has been maintained more regularly than usual this spring. It has now collapsed; and the situation of a large number of Midland pits which have been comparatively well employed has changed for the worse. Some of the merchants have not been able to clear stocks put down at the wharves, and appreciable loss in liquidation are almost inevitable.

The men employed at the Birchenwood Colliery, North Staffordshire, have rejected the proposal for the formation of a trust fund to continue the working of the pits on a co-operative basis. The well-being of Kidsgrove depends almost entirely upon the colliery, and the local authority is urging the Government in the public interest to intervene to avert a stoppage.

THE CALORGRAPH

New and Improved Pattern

The Records require no correction by Tabular Number.

Sound in Principle.
Substantial in Construction.
Unimpeachable in Accuracy.
Moderate in Price.
Uses no Liquid to Evaporate.

Recording Calorific Powers to 700 B.Th.U.

STOCK MARKET REPORT.

: failure of the New Zealand Loan issue, owed by the underwriting of the proposed 000,000 London County Council Loan to issued on precisely the same terms, had an erse effect on all investment stocks. In case of the New Zealand Loan, the under- ers were left with 85 p.ct. of their com- nents, so that the prospects of the Coun- Loan are not encouraging. The impetus ed for by the reduction in the income-tax not materialized; investors adopting a sive attitude. Foreign Government stocks recovered slightly at the end of the week, but French loans continued in a depressed state, and there is little hope of any material improvement for some time to come.

Industrial shares were more unsettled than usual, Rubber shares alone being the exception. With the price of the raw material rising to 2s. 7d. per lb., a keen demand took prices up with a run. Mining shares, although generally quiet, were well supported. In the Platinum group T.C.L.'s rose $\frac{3}{16}$ to $4\frac{7}{16}$ on rumours of fresh developments.

Quotations at :—*a.*—Bristol. *b.*—Liverpool. *c.*—Nottingham. *d.*—Newcastle. *e.*—Sheffield. * Ex. div.

The Gas Market was very active. The transactions were above the normal. Although there were several important falls in the quotations, notably Uxbridge Maidenhead and Wycombe, which dropped 5 points to 95-100, and Wandsworth (Epsom) 5 p.ct. stock 3 points to 112-117, it will be seen there were several upward markings. Among the recent capital issues were: Watford Gas, £50,000 "B" Capital Stock by tender, minimum par; Guildford Gas, £20,000 5 p.ct. Preference—minimum 90; York Town and Blackwater Gas, £10,000 5½ p.ct. Perpetual Debenture at par; and Southend Gas, £50,000 5½ p.ct. Irredeemable Preference, minimum par.

The following transactions were recorded during the week :

On Monday, Bahia Blanca "A" 2s. 7¾d., 2s. 9d., Bombay 5 *ex* div., Bournemouth "B" 12⅞, 12$\frac{11}{16}$, Brentford "B" 96, Brighton and Hove "A" 124½, 125, British Gas Light 7 p.ct. preference 124, Croydon maximum dividend 84, European 7, Gas Light and Coke 83½, 83⅝, 83⅞, 84, 84½, 3½ p.ct. maximum 63½, Imperial Continental 181, Primitiva 9s. 6d., South Metropolitan 93¾.

On Tuesday, Cape Town 4½ p.ct. preference 6, Gas Light and Coke 83, 83⅛, 83½, 83¼, 83⅜, 84, 4 p.ct. preference 80, 3 p.ct. debenture 60¾, Hastings and St. Leonards 5 p.ct. converted 95, Imperial Continental 181, Liverpool 7 p.ct preference 104⅜, South Metropolitan 93½, 93⅝, 94, 3 p.ct. debenture 60⅜, 61⅜, 6½ p.ct. debenture 103½, Southampton 4 p.ct. debenture 74½, 75, Tottenham "B" 98, 98½, Wandsworth 3 p.ct. debenture 58⅝. Supplementary prices, Barnet "B" 147, "D" Water stock 107½, Redhill 7½ p.ct. 102½.

On Wednesday, Brentford "A" 97, 5 p.ct. preference 95, 4 p.ct. debenture 77½, European 7, 7⅛, Gas Light and Coke 83, 83¼, 83⅛, 83⅜, 3½ p.ct. maximum 63½, 64, 3 p.ct. debenture 60½, Imperial Continental 181, South Metropolitan 93⅜, 94, 94⅛, 6½ p.ct. debenture 103, Tottenham "B" 97. Supplementary prices, Cape Town 5 p.ct. regd. mortgage debentures 74, 74½, Cheltenham 5 p.ct. maximum 79, 79½.

On Thursday, Bournemouth 4 p.ct. debenture 79, Brentford "B" 96, Continental Union 37, European 7⅛, Gas Light and Coke 83, 83⅛, 83⅜, 4 p.ct. preference 80, 3 p.ct. debenture 61¼, Imperial Continental 180, 183, 184, Malta and Mediterranean 9⅛. 3d., Primitiva 9s. 3d., 9s. 4½d., 9s. 7¼d., South Metropolitan 94, 94⅛, 3 p.ct. debenture 61¼, Wandsworth 3 p.ct. debenture 58. Supplementary prices, Cheltenham 4 p.ct. debenture 62, 62½, Tottenham 5½ p.ct. preference 104¼, 104½.

On Friday, Brentford 4 p.ct. debenture 79½, Croydon maximum dividend 83, 83½, Gas Light and Coke 83⅛, 83¼, 83⅝, 83⅜, 3¼ p.ct. maximum 63½, 4 p.ct. preference 79, 79¾, Imperial Continental 182, 183½, Primitiva 9s. 3d., 9s. 6d., South Metropolitan 93½, 93⅝, 93⅜, 94, 94⅛, 3 p.ct. debenture 60⅝. Supplementary prices, Petersfield and Selsey 26s., 5 p.ct. preference 46s. 3d., 47s. 6d., Sutton 105.

In Lombard Street the chief interest was the Bank's purchase of £1,610,000 bar gold which played a definite part in easing the short loan market at the close of the week. Several dividend payments also assisted to this end, loans being obtainable at as low a rate as 3 p.ct. Treasury Bills for £28,000,000 were allotted at an average rate of £4 13s. 5·56d. p.ct., being nearly 3s. advance on the previous week's rate.

On the Foreign Exchange Market there was a good demand for sterling-dollars, and the rate closed at 4.85½. French francs were cheaper at 93.40, and Belgian francs at 96.35. Italian lire closed at 118.80.

Bar silver was fixed at $\frac{1}{16}$d. higher for forward delivery, the cash price being 31$\frac{3}{16}$d. Orders were received from both India and China.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

TRADE NOTES.

Messrs. T. C. Jones & Co., Ltd.

This firm have just published a new hand and machine tool catalogue, which is fairly representative of the requirements of general engineers and contractors. The stock of lathes, and milling, shaping, drilling, and shearing machines is constantly being added to by the firm, and delivery of all types from stock can usually be had.

Dehydrating Plant and Tar Works Equipment.

A new catalogue has just been issued by Messrs. W. C. Holmes & Co., Ltd., in which they describe their latest plants for the distillation of coal tar by means of steam heated and fire heated continuously operated stills. The application of the Winker system to this process, in conjunction with the Hird still, or, indeed, any other type, is of interest to engineers and gas authorities already dehydrating or distilling their own tar; for, by adding a still of this type, a considerable increase in the capacity of an existing installation can be secured. The theoretical considerations involved are fully explained in the booklet.

York Town and Blackwater Debenture Issue.—Tenders for £10,000 of 5½ p.ct. perpetual debenture stock of the York Town and Blackwater Gas Company, which was offered by Messrs. A. & W. Richards, amounted to £24,400, and ranged from £105 down to the minimum of par.

South Suburban Gas Company's Standard Price.—The Public Control Committee of the London County Council have still under consideration the question of the action to be taken with a view to securing a revision of the standard price applicable to the South Suburban Gas Company.

CONTRACTS OPEN.

Coal.

Tenders are invited by the Slough Gas and Coke Company for the supply of 6000 tons of best screened gas coal. [See advert. on p. 547.]

The Directors of the Gloucester Gas Light Company are inviting tenders for the supply of about 30,000 tons of screened gas coal. [See advert. on p. 547.]

The Gas Committee of the County Borough of Stoke-on-Trent are inviting tenders for the supply of 93,500 tons of gas coal and 13 tons of steam slack. [See advert. on p. 547.]

Lea Bridge Preference Stock Issue.—Particulars will be found in our advertisement pages to-day of an issue by Messrs. A. & W. Richards, of No. 37, Walbrook, E.C., of £30,000 of 6 p.ct. irredeemable preference stock in the Lea Bridge District Gas Company. The new capital is required to meet the outlay on extensions of the works, mains, &c., rendered necessary by the constantly increasing demands for gas.

Gas Price at Burnley.—Explaining to the Burnley Town Council the Gas Committee's decision to increase the price of gas 1d. per therm, Alderman H. Emmott (the Chairman) stated that it would only cover half the estimated loss of £12,200. The balance would be taken from the reserve fund. The reasons for the loss were the estimated drop of £5000 in coke as compared with the previous year and £4700 in tar, with the payment of £5000 more in wages.

Conspiracy and Protection of Property Act, 1875.

Section 4, Printed on Broadside Sheets (22½ in. × 17½ in.) for posting in Gas-Works

Price **4/-** per dozen, plain; or **12/-** per dozen, mounted on strawboard, eyeletted, corded, and varnished. Postage extra.

WALTER KING, Ltd., "GAS JOURNAL" Offices, 11, Bolt Court, Fleet Street, E.C. 4.

NOTICES TO CORRESPONDENTS, ADVERTISERS, AND SUBSCRIBERS.

No notice can be taken of anonymous communications. Whatever is intended for insertion in the "JOURNAL" must be authenticated by the name and address of the writer—not necessarily for publication, but as a proof of good faith.

COPY FOR ADVERTISEMENTS for the "JOURNAL" should be received at the Office NOT LATER than TWELVE O'CLOCK NOON ON TUESDAY, to ensure insertion in the following day's issue.

Orders to Alter or Stop PERMANENT ADVERTISEMENTS should be received by the FIRST POST on Monday.

UNDISPLAYED ADVERTISEMENTS; Situations Wanted, Six Lines and under (about 36 words), 3s.; each additional Line, 6d. Situations Vacant, Apparatus Wanted and for Sale, Contracts, Public Notices, &c., 9d. per Line—minimum, 4s. 6d.

TERMS OF SUBSCRIPTION to the "JOURNAL."

EDITORIAL NOTES.

Pricking the Bubbles.

E bubbles by which the Government electricity develop-nt ideas are being supported have been pricked in a ·st effective manner by the President of the Society of itish Gas Industries (Mr. D. Milne Watson, Governor the Gas Light and Coke Company, and President of : National Gas Council). He performed this task in Presidential Address which he delivered to the Society t Wednesday. Whether he has caused the bubbles to rst loudly enough to impress the Government cannot said; but at any rate they cannot ignore the utter-ces of one who officially stands at the head of the ganizations of the gas industry, and is the Governor the largest gas undertaking in the world. It was a sterly, analytical, and statesmanlike deliverance; and a criticism of the movement which is being politically gineered to render State-aid to the electricity industry probably both in money and legislative influence—thing has hitherto been done to equal it, nor have we seen any speech that has been made by any political der in support of preferential legislative treatment of ctricity which has shown a tithe of cogency construc-ely that this address presents destructively. The point, wever, should be made clear that the gas industry does t want to stand in the way of any legitimate develop-ent of the electricity industry. But it does object to usual facilities being granted to that industry to aid development on pseudo-national grounds, which have en adopted politically through misconception and mis-ding, and which, while not improving matters nation-y, would act detrimentally upon an industry doing ually important national work, though unrecognized the powers-that-be who have been captured by the *parte* evidence of those electrically concerned. The uble is that the final determination of this matter rests the hands of politicians whom the Right Hon. r Alfred Mond (the new President of the Society of itish Gas Industries) describes as "ignorant men on chnical matters." We will not admit that the descrip-n entirely applies; but it does in the main to those who ve been the loudest and most persistent among the ad-cates of the State taking electricity specially under its ng. And these are the people who (as Sir Alfred puts talk gaily about super-power stations, but who do t know the difference between a volt and an ampère, d who have never seen a dynamo. The critical address is come very opportunely; and it has been decided to rry out a suggestion of the new President to send a copy it to the Prime Minister, the Minister of Transport, r. Lloyd George, Mr. Snowden, and other members of rliament. Well-placed copies in municipal councils uld also do good.

The whole matter, as Sir Arthur Duckham says, is of tal importance not only to the gas industry, but to the tion at large. It is so because the problem involved is been considered only from the point of view of an dustry which in its very best practice shows an inefficiency of 80 p.ct., while consideration should have been given to the whole problem of the utilization of our fuel resources for the provision of power and heat. That is where a fundamental error has been made. At the present time, one does not know anything positive as to the character of the report that has been made to the Government by Lord Weir's Committee, or as to its recommendations. It would appear almost as though the report contains features that were unexpected by the Government. It was anticipated that a statement on their policy in the matter would have been made in the House last Thursday; but Lieut.-Col. Ashley, Minister of Transport, stated that the draft of the report was only received the previous Friday, and the complete report on Wednesday. He could not even say whether or not the report would be published. If it is not, it will seem very much as though there is something in it that the Government wish to hide. Being a national question, the nation have a right to be informed of all that there is to be known regarding it. Should, therefore, the Government not voluntarily publish the report, they should be pressed to do so until they yield, so that it may be discussed not only from those points of view that are convenient politically, but from those that are economically and technically important. However, whatever is in the report, the credulity of certain members of the Government will probably remain undisturbed. When speaking last Thursday, the Minister of Transport stated that, if the Government approached this matter from the national point of view, they could "hammer out" a scheme which would give a cheap and general supply of electricity. He added that, if this were done, he felt sure they would present to this country a weapon whereby it would be able more effectively to deal with foreign competition. The mischief of this sort of political scheming and talk is that we do not suppose Lieut.-Col. Ashley has a ghost of a notion of the extent to which any accruing difference in the cost of power would affect the competitive position. If he ascertained what proportion of works cost in any process of manufacture the item for power represents, we are sure he would not talk at random in the manner he does on this question. Neither do we believe he has any idea that the best practice of electricity shows only 20 p.ct. efficiency, and that under the national scheme it may easily be that more will be lost in distribution than is gained through another modicum of economy being derived from the fuel costs of electricity generation. How this is going to assist in putting this country in a better position competitively is a complete mystery; the chances are equally great that it will worsen our position in that respect, and weaken our internal security.

That the gas industry is entitled to the consideration of the Government when dealing with the question of the provision of power and (as they should be doing) heat, is clearly shown by some remarkable data presented by Mr. Milne Watson in his address. In Great Britain, the consumption of gas amounts to 275,000 million c.ft. annually, which is equal approximately to 1320 million therms. Taking the population at 47,350,000, the consumption of gas works out to 28 therms per head. The amount of electrical energy required to do the work actu-

ally performed by this quantity of gas, in its varied uses by the public, is calculated by the President at 487 KW.H., while the consumption of electricity in the country is only 139 units *per capita*. In the computation which brings out the equivalent figure of 487 KW.H., the President has been characteristically generous to electricity in the matter of efficiency in use. The figures should cause the Government to pause, and inquire into the actual reasons for their existence. Again, if the Government feel any responsibility in regard to the question of the conservation of our national fuel resources—before moving in the matter of promoting, on false premises, conditions to aid the development of the electricity industry other than by its own exertions and natural growth—they should take into account the position of the two industries in respect of the efficiency of the use of coal. It would be nothing less than a scandal that State funds should be employed to foster the inefficient use of coal, and so encourage waste of our resources. The address should make it quite clear to the Government and to members of Parliament generally that the problem of power and heat supplies in this country is being attacked from the wrong end. Furthermore, as Mr. Milne Watson points out, the grant of subsidies for the development of industries (particularly sheltered ones) is wrong in principle; and, inasmuch as the gas industry has paid for its own development, and occupies such a prominent place in the system and service of the country, it has a right to be heard on this matter, and to be furnished with the exact grounds on which the Government base their case for giving preferential consideration to a competing industry. The title of the industry to this information, and to be heard respecting any case that can be put forward, is accentuated by the fact that as a tax and rate payer it is an enormous contributor to national and local finances. If at all possible, therefore, the fullest satisfaction should be given by the Government that their proposals are right, and not economically and technically wrong. Anyway, if they will not pursue these suggested and just courses, then, if there is insistence by Parliament on subsidies being given to electricity, the claim of Mr. Milne Watson should be honoured, that subsidies should only be granted by way of loans, and in fairness to other industries loans should be allowed to them on like terms. But it would be much better that there should be no subsidies. As a matter of fact, the electrical industry is not in need of capital; and the dividends paid (far in excess of the controlled ones in the gas industry) show the ability of the industry to attract all the capital it requires.

The idea that this development of electricity will materially assist industry is proved by the address to be purely hypothetical, as witness the happenings on the north-east coast; and so is the idea that it will in any way improve employment. If by the aid of the public purse (to which the gas industry so heavily subscribes) electricity is cheapened for power purposes, and the ideas of the Government mature as to the lowering of the costs of industrial production (which we very much doubt), would it not follow that industry would prefer to adopt more extensively mechanical means in place of manual labour? The Labour Party have all through the piece been profoundly blind in this matter; and they have not even been aware of a fact which is put forward in the President's Address, and which should arrest their attention. It is that the gas industry employs more than five men for every one that electricity employs for the same amount of heat energy. The industry which labour should assist in developing is the one that offers the larger field for employment. But nationalization is in view; and the electricity industry appears to be an easy victim. To secure it—to satisfy a meretricious item of policy—is something, in the view of the Labour leaders, that is worthier of fervent work and blatant advocacy than the cause of employment. Electricity is not the solution of the unemployment problem; to say that it is, is nothing more than a political stunt and gross deception.

The members of the Society of British Gas Industries are as deeply concerned in this matter as the gas-supply industry; and they are as grateful to their President for his brilliant examination of the position and exposure of claims as will be those who have the responsibility upon them of guarding the interests of gas supply.

The Miners' Enlightenment.

Out of the bad conditions in the mining industry go may come in the enlightenment of the miners as to t destructive effects of the bad policy of the extremists the past. The miners have been blindly following the leaders; and it is a shock to them to find that it has l them to a position at which this country cannot in r spect of coal successfully compete with other countrie Thus sales have seriously diminished, prices have had fall, profits for many of the old pits are negligible non-existent, some 160,000 miners are out of work, ma thousands are on short time, and the number increas daily. Why? Largely because of the reduction of t output of coal per shift, and therefore the much high cost of wages per ton. And the item of wages, being th greatest in the total cost, is the one which has the heavie effect in preventing competition with other countri where the conditions are the reverse—where there greater production per man shift, and thus a lower co for wages per ton. The position will not be altered wit out the miners themselves move. Large sections are st showing resistance. But knowledge is growing that t men have been led by the noses into the present mess b the ultraists among their leaders. It was bound to com and come it has with disastrous effects upon the mine themselves. Many of them are now realizing that t flouting of economic conditions cannot be carried on i definitely; but in the end there will be a rebound, to t injury of those who have been fools enough to think th they are omnipotent in such matters. Hence the numb of miners is increasing who desire to see a retracing steps to saner conditions, and who are willing to help bring them about. But those conditions would nev have grown so severe had it not been for those wil brained individuals who thought they could effect perm nent good by supplanting order by disorder. Instead improving the miners' conditions, they have worsen them; and even now are trying to save their faces b urging them immediately to give notice to terminate t national agreement, and to present a new proposal f wages. They have still a good following; but, fort nately, not one which can do harm, as was seen last we at the Blackpool special delegate conference when t proposal of the Executive of the Miners' Federation, th the Joint Committee of owners' and miners' represent tives should continue their investigations into the con tions of the industry, was agreed to by 571,000 to 230,0 votes—although an amendment had been moved to t effect that new wage proposals should be drafted.

That vote shows the way the wind is blowing amo the men. Last week we referred to other indication fresh ones have been made during the interval. One the principal of these was a letter in "The Times" Mr. James Meadows, Financial Member, South Wal Miners' Federation, Rhondda Main Lodge. It was letter which acknowledged that the policy of the p had been wrong, which made no secret of the evil r sults, and which suggested a line of policy that wou promote relief from the present situation. Mr. Meadow showed the serious amount of unemployment and part employment existing among the South Wales miner and then he said: "We miners here, in common wi those in other exporting districts (though not to the sar extent as we have), have been living in a fool's paradi since 1916 or 1917. Those were the days of ca' cann and from the fruit of that evil policy we are to-day suffe ing." He sketched the appalling condition of wives a children; and then he said that the duty of the delegat conference was to present proposals which would arre the slump, and so give our export coal a chance in t markets of the world. Whether this suggestion was co sidered at the conference is not stated in the meagre new paper reports. The views of this sapient leader are th forthwith there should be a reduction of the price of co by 4s. Labour costs, he asserts, could be eased by per ton; and the railway authorities, as in German should allow 1s. per ton off the carriage of all export coal. That in his judgment is the solution, and the ro by which prosperity will again come back to the mini industry. In our opinion, and in that of a good ma fully competent judges, he is right. We like the spirit the letter; also the strength of will which (if supporte

ould send the extremists and their destructive policy to her business than that of misleading the miners. Says r. Meadows: "We miners can do it. We can reduce bour costs by 3s. per ton; and we will do so before we ill see our vital industry perish. Even Mr. Cook can- ot stop us. There is a determination in South Wales nyhow to get away from crippling the mining industry, nd to assist it to get on its feet and find work for the o,000 partially unemployed and the 50,000 totally un- nployed." Unless this is done, he sees further misery r the men, their wives, and children. Mr. Frank Hall, ie Derbyshire miners' leader, has advised the men to t tight, and abide by the conditions of the moment, as e is not foolish enough to say this is an opportune time o end the agreement. He states that throughout the ining areas there are 160,000 miners without work; nd there is no single union which could stand a strike r any length of time. As to amalgamation with the ailway and transport men, Mr. Hall says there are housands of railway men unemployed, and the transport orkers are split up into forty or fifty unions. There oes not seem much chance of cohesion in those circum- tances. But the agitator Cook only last Saturday, in ddressing the West Auckland miners, expressed the iew that the miners' conditions justified a strike. But he s not silly enough to think they can fight alone; and so e devoutly hopes the engineering, railway, and transport orkers will on June 4 decide on a "practical brother- ood," thus helping the miners to secure relief from the resent mess into which he and others have brought them. But he wants the relief to come by his own route, and not y that which better balanced minds know is the only ane and safe one. The methods of the wild men would nly precipitate the miners into a state of greater chaos nd immeasurable misery.

Specifying and Inspecting Piping on Consumers' Premises.

To inspect, adjust, and maintain gas-consuming appli- nces (excepting the provision of materials) is only one art of the service which should be rendered by gas under- akings, in order to ensure efficient use on consumers' remises. That is a matter vital to business maintenance nd progress in these days when the severity of compe- ition is growing and is being preferentially assisted by political benevolence. That work, however, should be complementary to something else. Supervision by the suppliers of gas, who are the most competent and in- terested people, should extend to the efficient piping of new buildings, with power to condemn old piping which has reached a dangerous state or is no longer capable, through insufficient carrying capacity, to meet require- ments. Authority in the latter respect is highly desirable, because the greater proportion of houses were piped when there was no thought of gas becoming the popular heating agent that it is to-day. But there is no use what- ever in being able to condemn if there is no accompany- ing authority to refuse to supply appliances beyond the capability of the piping to render service. That seems to be a defect in the specification authorization which has so far been statutorily granted. There may be refusal to supply if new or renewal piping is not according to speci- fication; but nothing is said as to cases of insufficiency or defects on old premises. That is where much inca- pacity resides, and where revision or renewal is much needed. Power to specify and ensure that new premises are properly equipped will, of course, prevent architects and builders putting-in, for economic reasons, piping that cannot fully meet the probable ultimate requirements of the tenants.

As already indicated, several undertakings have to-day statutory power to specify piping; and no undertaking which has that power would be without the assurance it gives of keeping things right for the future. Among the suppliers who have the power are the Halifax Cor- poration; and Mr. W. B. M'Lusky, the Engineer and Manager of the Department, introduced a discussion on the subject at the meeting last Friday of the Manchester District Institution of Gas Engineers. It will be seen from the report in other columns that the sections of the Halifax Corporation Act of 1920 are quoted which confer the power to specify, inspect, and test new, renewal, or extension piping on any premises. It will also be noticed that different specifications may be made for different classes of premises. If the Corporation find that there is not compliance with their specification, and refuse to supply until there is rectification, the occupier of the premises has the right to appeal to a petty sessional court; but there would be little hope of success if avoid- able departures from the specification could be proved. The Halifax specification is given *in extenso*. It ap- pears to be comprehensive, contains much useful infor- mation, and will be of value to others in entering upon this work, though it may not square in every detail with the present or prospective prescriptions of others. In the specification is noticed the provision that where gas and electricity supplies are being used on the same premises, the gas-pipes must not be fixed at a less distance than a foot from the electric wires. This reference to the subject is merely to direct attention to it and its importance; and to ensure consideration of the views of those who took part in the discussion at the meeting.

Institution Visits.

All the arrangements in connection with the annual meeting of the Institution of Gas Engineers, to be held under the presidency of Mr. J. Ferguson Bell, M.Inst.C.E., of Derby, are shaping splendidly. As to the visits, upwards of 250 members will be going to the Fulham Station of the Gas Light and Coke Company, to view the new Glover-West vertical retort installation now under construction. Simultaneously about 100 will visit the National Physical Laboratory; and about another 100 will inspect the Laboratories, &c., of the South Metropolitan Gas Company. In the visit to Derby, about 400 will be participating.

Praise for the Gas Exhibit.

To "The Times" Empire Day Number, Sir Lawrence Weaver, Director of United Kingdom Exhibits, contributed an article. Praise from the author of the exquisite volume "Exhibitions and the Arts of Display" is something of which to be proud. In the article, Sir Lawrence, writing of the Palace of Industry, remarks: "The British Empire Gas Exhibit stages once more its manifold public and domestic services in a changed setting of great architectural dignity, and has absorbed a large adjoining area in association with the Empire Food Demonstration Committee. Women visitors rejoiced in the gas show in 1924; they will with difficulty be lured out of its halls this year."

Ventilate the Bath Room.

A correspondent suggests that it would be a good thing, even where gas geysers are properly fitted, if users would turn-off the gas to the geyser and properly ventilate the room before using the bath. This would certainly obviate any danger. In his letter, our friend says: "There are still far too many acci- dents with geysers, which could be avoided if the user would always turn-off the gas to the geyser and ventilate the room, before having a bath. In no circumstances should the geyser be in operation while a bath is being taken. Every geyser should, of course, be fitted with a baffle, and a vent-pipe taken through to the open air and discharging above the eaves of the roof; but even when these precautions are taken, there is always a risk of down-draught under certain atmospheric conditions. It really amounts to this, that no one can fix a geyser, and say that under all conditions of atmosphere the flue will properly function." In the case of his Company, a card is issued with every geyser, with a suggestion that it should be hung in a prominent position in the bath room. The card bears, in bold lettering, this advice: "Before using Bath, Turn off Geyser Taps, and Well Ventilate Room." The Company have offered to supply the ironmongers and fitters in the dis- trict, on trade terms, with the necessary flue fittings for geysers, and with as many of the cards referred to as they desire, free of cost. Other undertakings may see fit to follow this good example.

Still Busy.

The revelations at the Barford inquiry as to the operations of the company promoting group at 43, Cannon Street (upon which comment was made in our issue for May 13, p. 445), have not deterred these gentry from raking-up some of their old prospectuses, and sending them out for the purpose of getting in more money. Further copies of the one which offers additional extension capital in the Chagford and Devon Electric Light Company, Ltd., have been received, and so have copies of that precious document referring to the Southern Counties Electric Light and Power Supply, Ltd. On the former the name of Eaton appears; on both are the names of the baronet Soame, Thompson, the Solicitor, and Turner & Co., the Auditors. Criticism of both these prospectuses has appeared in our columns.

Coal Exports.

The uneasiness over the position of the coal export trade is shown by the April returns to be fully justified. The total amount of coal exported in the month was 4,359,817 tons, as compared with 5,062,941 tons in April, 1924, and 6,841,423 tons in April, 1923. The value of the exports this April was only about half that for the same month of 1923—viz., £4,541,333, as compared with £8,914,748. The value for 1924 came about midway between the two—£6,326,197. The gas coal shipped last month accounted for 565,247 tons of the total quantity, compared with 691,449 tons in April, 1924, and 728,353 tons in April, 1923. The values were: Last month, £554,131; April, 1924, £837,902; April, 1923, £902,276. The average value per ton for gas coal last month fell below £1, or 19s. 7·28d. In the four months the total amount of coal of all kinds sent abroad totalled to 17,462,134 tons, compared with 20,768,891 tons in the corresponding period of 1924, and 25,535,825 tons in that of 1923. Of these quantities, gas coal represented respectively 2,286,093 tons, 2,673,295 tons, and 3,019,143 tons; the values attached being £2,314,933, £3,239,696, and £3,536,135.

Export Coke Doing Badly.

The export coke market is extremely unsatisfactory. In April, only 25,599 tons were shipped, as against 43,021 tons in April, 1924, and 87,885 tons in April, 1923. The values of these quantities were respectively £30,902, £76,509, and £138,043. In the corresponding four months of the three years, the quantities exported were: This year, 183,777 tons; 1924, 369,476 tons; and 1923, 382,438 tons. The values of these shipments were: This year, £270,987; 1924, £645,870; 1923, £566,984. The average value for April was only £1 4s. 1·75d., as against an average of £1 9s. 6d. for the first four months. In April last year, the average value was £1 15s. 6·8d—better than last month by 11s. 5d.

Sulphate of Ammonia.

Business in sulphate of ammonia abroad distinctly looked up last month. The quantity exported was 19,445 tons, as compared with 12,148 tons in April, 1924. In the four months, 99,052 tons were shipped, as against 99,406 tons in the same period of last year, which is close showing. Spain and the Canaries were good customers in the month, with 11,296 tons; and their total purchases during the four months have amounted to 39,995 tons. Japan comes next in the four months with 17,082 tons, and Dutch East Indies follows with 15,167 tons.

Coal Tar Products.

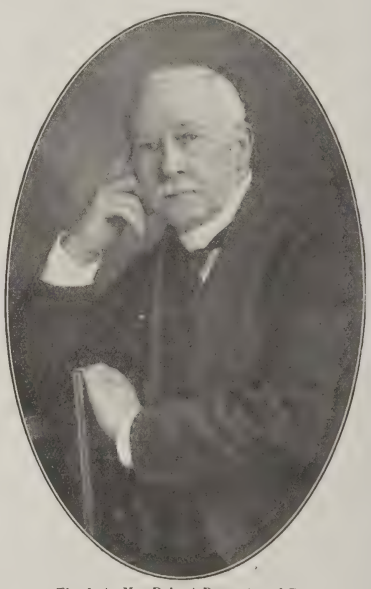
The amount of benzole exported during April was 19,588 gallons, as compared with 10,545 gallons in April, 1924. The quantity shipped in the four months of the year was 135,109 gallons, as against 263,294 gallons. Of naphtha only 4331 gallons were exported in April, compared with 50,206 gallons in April, 1924. In the four months, 15,226 gallons were shipped, which is small in comparison with the 100,003 gallons in the first four months of 1924. Combining the exports of tar, oil, creosote, &c., 1,115,066 gallons were sent abroad last month, as against 1,999,073 gallons in April, 1924. In the four months, 11,944,012 gallons were shipped, as compared with 11,512,821 gallons in the same period of 1924.

OBITUARY.

ROBERT DEMPSTER.

It is with great regret that we announce the death at Cape Town of Mr. Robert Dempster, J.P., of Vale Royal, Cheshire. Mr. Dempster was the Senior Member of Messrs R. & J. Dempster, Ltd., of Gas Plant Works, Manchester. He was born at Dundee on Feb. 16, 1853, and was the eldest son of the late Robert Dempster, of Elland and Penmaenmawr. Of late years the deceased had not been as prominent in our public life as in years gone by, when, with Mrs. Dempster, he was a regular visitor to our annual meetings. He, however, never lost touch with the industry in which he had for so many years taken such an active part, and regularly attended Directors' meetings at Manchester. He was also a Director of several Iron and Chemical Companies.

Mr. Dempster was always a great traveller. Many years ago he made a world tour, and visited numerous foreign gasworks. Although during last year his health was very unsatisfactory, he was of the opinion that a sea voyage to South Africa would be beneficial. A post-card received on the day of his death, posted at Victoria Falls, stated how well he was feeling, and that he proposed to travel through to Cape Town (a distance of 1700 miles), with only one stop for rest. Until further news is received, we can only surmise that the effects of this long train journey proved too much for him; for his death occurred there on May 17.



The Late Mr. Robert Dempster, J.P.

Mrs. Dempster predeceased her husband; and the deceased leaves two daughters, Mrs. W. F. Perkins and Miss Edith Dempster, J.P. The latter was accompanying her father on what has proved to be his last journey.

Mr. Dempster for many years has resided at Vale Royal. Only recently he excavated the remains of a Cistercian Abbey, accounts of which have already appeared. His mind was always receptive to improvements in machinery; and the splendidly equipped works at Manchester are largely due to his organization—he being always on the *qui vive* for new ideas in this direction. His wide knowledge of men, and love of travel, enabled him to view the things of to-day with a broad outlook, which made him a most agreeable companion. Strange to say, when he left England he was due to return on the s.s. "Windsor Castle," which boat is bringing the body, to be buried at Whitegate Church, Cheshire.

Dr. Davidson's Claim on the War Office.—We understand that the Royal Commission on Awards to Inventors who considered the application of Dr. W. B. Davidson in respect of a process for the extraction of toluole from coal gas (see *ante*, pp. 322, 381) have recommended to the Treasury that £350 should be paid to Dr. Davidson as remuneration in respect of all uses, past, present, and future, by the Crown of his process. Sums expended by Dr. Davidson in producing and testing the process were considered in arriving at the award stated.

PERSONAL.

Mr. J. H. Canning, Engineer and Manager of the Newport (Mon.) Gas Company, is the new President of the Rotary Club of Newport.

We have pleasure in announcing that Mr F. G. Brockway, son of the late Mr. E. J. Brockway, J.P., of Cleethorpes, has been appointed Manager and Secretary of the Cleethorpes Gas Company in succession to his father.

The marriage took place at Southampton, on May 23, of Mr. Frank Henry James, Secretary of the Imperial Continental Gas Association, to Mary Margaret, younger daughter of Mr. and Mrs. Charles Fox, of Merrietrees, Ambridge, near Romsey.

Upon completing 25 years as Secretary to the Cannock, Hednesford, and District Gas Company, Ltd., Mr. T. A. Nicholls has been presented by the Directors with a grandfather clock, with Westminster chimes, as a mark of appreciation of his services.

Mention was made in the "Journal" for May 13 of the forthcoming retirement of Mr. W. S. Haddock from the position of Gas Engineer and Manager to the Warrington Corporation. Born in Warrington, Mr. Haddock was in 1877 apprenticed to Mr. James Paterson, who was at that time Engineer of the gas-works, which had just been acquired by the Corporation from the Gas Company. Later he became deputy to Mr. Paterson, and was appointed Manager in July, 1888. In 1888-89, the quantity of gas sold and accounted for was 178¾ million c.ft., while in the year just ended (1924-5) it was about 534 millions, or rather more than the figure for 1914-15. The price in 1888-89 was 3s. per 1000 c.ft., and in 1923-24 2s. 10d.; a figure of 2s. 1d. having prevailed for a number of years in the interval. Woodall-Duckham vertical retorts were erected in 1922. The net profit made during Mr. Haddock's management, up to the end of 1924, was £223,000.

Mr. Albert Cook, who will take up the duties of Gas Engineer and Manager to the Warrington Corporation as from July 1, was in 1910 articled to the late Mr. T. O. Paterson, then Engineer and Manager to the Birkenhead Corporation Gas Department. On completion of his articles, Mr. Cook was appointed Assistant Clerk of Works, and later Assistant Works Superintendent. During the five years he spent at Birkenhead extensive alterations were carried out, including a spiral-guided holder of 2½ million c.ft. capacity, a 2½ million installation of vertical retorts on the Woodall-Duckham system, a large power house, exhauster house, residual wells, new carburetted water gas plant, showrooms, high-pressure mains, &c. For three years to the end of 1918 he was Assistant Works Superintendent to the Wolverhampton Gas Company; and then he went to Warrington, first as Works Superintendent, afterwards to become Chief Assistant Engineer and Manager.

FORTHCOMING ENGAGEMENTS.

May 29.—Chemical Engineering Group of the Society of Chemical Industry.

Sixth annual general meeting at the Chemical Industry Club at 8.15. Mr. C. S. Garland, B.Sc., A.R.C.Sc., F.I.C., Chairman of the Group, will preside. The meeting will be preceded by an informal dinner in the Club at seven o'clock.

June 5.—Southern Association of Gas Engineers.

Visit to the works of the Bournemouth Gas and Water Company.

June 6.—Scottish Jr. Gas Association (Eastern District).

Annual outing at Anstruther.

June 8.—Institution of Gas Engineers.

Council meeting at No. 28, Grosvenor Gardens, at 2.15.

June 8.—Evening Star Lodge.

Regular meeting, at 5 p.m., in the Grand Temple of the Freemason's Hall, Great Queen Street, London.

June 9-11.—Institution of Gas Engineers.

Annual general meeting in the Great Hall of the Institution of Civil Engineers, Great George Street, Westminster. At the termination of Thursday's meeting, a Council meeting will be held at the Institution of Civil Engineers.

June 10.—Association of Statutory Inspectors of Gas Meters.

Annual general meeting at the new County Hall, Westminster. The afternoon will be devoted to a visit to the Finsbury gas meter testing office.

June 11.—Coke Oven Managers' Association (Midland Section).

Visit to the Barugh plant of Low-Temperature Carbonisation, Ltd.

June 12.—Institution of Gas Engineers.

Visit to Derby. Members should note that the luncheon will be in the Drill Hall, Derby—*not* the Assembly Rooms, as indicated in the programme.

June 20.—London and Southern District Junior Gas Association.

Visit to the Cambridge Gas-Works.

ELECTRICITY SUPPLY MEMORANDA.

Poplar has done many queer things in its time, and owing to a propensity for throwing away the money of the ratepayers without getting a fair return for it, the Council have got into serious hot water. They have now taken to heating water by electricity for the public baths. From the point of view of those who control these, the transaction is regarded as all right. From the point of view of the electricity undertaking, it cannot be so described; from the national point of view, it is a disgraceful waste of fuel. "Meteor" of the "Electrical Times" says: "Our friends the gas men always assume the electric heating of water to be an impudent stunt." It is. "They regard it as particularly preposterous where large bodies of water are in question." It is. "We put it to them, however, that it is cheaper than gas for heating public baths on a large scale." It is not. "Poplar," we also read, "has thrown out its gas heating at the baths because it is too expensive; it has replaced gas by electric heating, because the latter is cheaper." The comparison is made with gas at 3s. 9¾d. per 1000 c.ft., or 9·15d. per therm, which includes all costs, even the capital charges, while electricity is taken at the bare fuel costs, or a little over—so little that calculation hardly enables its detection. No other generating costs are included; and nothing for distribution, capital, or other charges. The current has to be taken at off-peak load times—between 5 p.m. and 8 a.m., after 1 p.m. on Saturdays, and between noon and 2 p.m. every day. At such times, the generating plant is not working at its best efficiency, so that the fuel costs then would be somewhat greater than the average figure. Those conditions—particularly the difference between what is comprised in the charge for gas and that for electricity—"Meteor" considers are things which can be ignored, and, by ignoring them, he feels justified in saying that electricity is "cheaper" for the purpose of water heating. It would be cheaper still if the "real live" Electrical Engineer of Poplar decided to rule-out the fuel costs, as he has done everything else in supplying energy to the public baths. Notwithstanding gas being supplied on a commercial basis and electricity not, "Meteor" says that the cost for electrical energy actually works out at 2·33d. per bath; for gas it averaged 2·23d. per bath. Now if the Gas Company had been such asses as to have supplied gaseous energy at bare net fuel cost, can "Meteor" guess where electricity would have been in the comparison? We are also wondering whether he knows what it means "to play the game."

Poplar Washes and Wastes.

In view of the foregoing, it seems absurd to follow-up this Poplar public baths heating scheme; but we confess to being interested in the data attaching to it, which are found in a paper that Mr. Jefferson Hope, the Baths Superintendent at Poplar, read at the annual conference of Baths Superintendents in Leeds. He takes the average slipper bath as requiring 30 gallons of water at 110°. Assuming the temperature of the inlet water to the heater is 50°, the 30 gallons would require (without any stand-by and other heat losses) 18,000 B.Th.U. to raise the temperature to 110°, or 5·26 units. Naturally, with the heat losses, more energy would be needed than that. A swimming-bath containing 80,000 gallons of water raised in temperature from 50° to 74° would require 19,200,000 B.Th.U., which again takes no account of heat losses, or of heat to maintain the temperature at 74°. Mr. Hope takes the calorific value of the coal used for the boilers at 12,000 B.Th.U. per lb., which is equivalent to 26,880,000 B.Th.U. per ton. We have not the generating figures for Poplar; but we will adopt an average consumption of 2·24 lbs. of coal per KW.H. generated, or 1000 KW.H. per ton, which would be equal to 3,420,000 B.Th.U. per ton. On this basis, to generate sufficient energy to supply 19,200,000 B.Th.U. to the swimming bath (without taking into account heat losses and compensation heat) 5·61 tons of coal would have to be consumed at the generating station. Take a boiler using coal and (or) coke at 75 p.ct. efficiency—there are records of higher efficiencies than that—20,160,000 of the 26,880,000 B.Th.U. of the ton of fuel would be transmitted to the swimming bath water. That is more than the heat required for raising the temperature by 24°. Mr. Hope takes an efficiency of only 25 p.ct. for coal-heated boilers used for raising the temperature of bath water, which means a waste of 75 p.ct. of the heat of the coal. This efficiency probably applies to the slipper baths with their intermittent requirements; but if we accept that as representing the efficiency for also providing the swimming bath water, it means that more than the heat transferred to the 80,000 gallons of water (19,200,000 B.Th.U.) would be realizable from 3 tons of coal. The 1 ton or the 3 tons compares with the 5·61 tons required for electricity generation to provide the same amount of heat. All we need say is that this is a scandalous misuse of coal. Incidentally, it may be mentioned that there are gas-fired boilers on the market which give an efficiency of 80 to 85 p.ct.

Extravagant Heat Expenditure.

Charged for Fuel Only.

Mr. Hope further states that the Borough Electrical Engineer agreed to supply current at off-peak load times at "a little over station fuel costs." This no ordinary commercial undertaking could do, and assert that it was a good commercial transaction. The charge per unit is 0·517d., and in the first (September) quarter's working, the cost per slipper bath was 2·33d.; the consumption being 4·52 units. If that is so, and the volume of water per bath was 30 gallons and the temperature 110°, then the temperature of the inlet or unheated water was more than 50°. In the December quarter, consumption averaged 6·04 units, which raised the cost for current per bath to 3·1d. If Poplar's present system of heating public bath water proves anything at all, it is that it is a waste of fuel, and of no advantage to the electricity undertaking, in that the current is supplied at a shade over fuel costs. This is not business on competitive lines; and therefore "Meteor's" thin boasting falls miserably to the ground.

Electric Cooking in L.C.C. Schools.

Nearly two years ago—to be exact, on July 31, 1923—the London County Council passed a resolution requesting the Education Committee to consider and report whether or not at appropriate centres cooking by electricity should be taught. The Committee have now reported that they have given the matter careful consideration. The time suggests that this must be true; but the fact that the Committee have arranged for only "experimental" installations at certain cookery centres appears to indicate that they are not yet satisfied that, for those who attend the Council schools, electric cooking is precisely what is required. We put this to the Committee—that all that can be taught in the schools which differs from instruction with a gas cooker is the management of the electric cooker. Heat is heat; food is food. When one comes to competition between the two systems in schools, then, if the young people or their parents are not to be "taken in," they must be told the relative costs (not at cut electrical prices per unit) of doing an equal amount of work on the two types of cooker—including all boiling operations such as are common on a gas-cooker in an ordinary house. We know Labour members of local authorities are keen to advance the interests of electricity—not that, on their own confession, they know much about the matter (other than the usual electrical platitudes), but the political policy of the Labour Party is nationalization, and electricity has been entered among the industries and services which are to come under State control in those wonderful days that are to come. Any and every step which will help towards this end is being taken by nearly all who profess and call themselves Labour-Socialists. They are to be pitied. Some of them are mentally as blind as bats, and badly require educating to assist them to see things in their true form. However, the Education Committee of the London County Council are going to watch the school experiments carefully, and a further report will be submitted when sufficient experience has been gained. That report, when in due season it arrives, will be read with interest, analyzed with care, and commented upon with justness and prudence.

Bad Companions.

In the equipment of buildings, electric light wires and gas-pipes should not be immediate companions. This has been demonstrated in no uncertain manner from time to time. According to the newspapers, the Royal Sussex County Hospital at Brighton—a hospital above all places—had a serious experience last Saturday week. An electric wire fused, which melted a gas-pipe, and ignited gas. Fortunately there was no panic among the patients; and the flames were got under in about half an hour. But it was an exciting half-hour. We have not yet seen an electrical contradiction of the fusing, nor, strange to say, has there been any authoritative statement to the effect that the gas-pipe was melted by a burning cigarette end, which some careless and uneconomical person threw away.

Mr. Pearce and Electricity Reorganization.

The Manchester Corporation are, it appears likely, about to lose the services of Mr. S. L. Pearce, General Manager and Engineer of the Electricity Department, who has rendered the city excellent service. He has been offered an important post by the Government. It is understood that it is in connection with the electricity reorganization schemes, so that, we take it, he will, if the appointment is accepted, become associated with the Electricity Commissioners.

Barking!

The electrical feature of last week was the starting, by His Majesty the King, of the large Barking Station of the County of London Electric Supply Company. It is the first super-power station for the Metropolis. Its ultimate capacity will be upwards of 750,000 H.P., or (say) 600,000 KW.H. The section inaugurated contains plant with a capacity of 125,000 H.P. or (say) 100,000 KW.H. For this, one report states, more than 4000 tons of coal will be required per week. We cannot vouch for the accuracy of this. The engine-room is designed for four turbo-alternators—two of 50,000 H.P. and two of 25,000 H.P. They produce current at 6600 volts; and this pressure is raised by transformers to 33,000 volts for economical transmission to sub-stations at a distance. Upon the first section of the power house and mains £2,500,000 has been expended, about £1,000,000 of which has gone in transmission mains. The whole station may be said to typify latest practice in efficient generation on a large scale; and it is the first real contribution to the unification of the electrical system for London and the Home Counties. One report, however, states that a wholly unified system for that large territory can hardly be expected before 1971. The electrical people consider this new station something really magnificent. They should, in order that heads may not get too inflated, have attention drawn to the reminder given by Mr. Milne Watson in his Presidential Address to the Society of British Gas Industries, that to supply to the community the heat energy delivered in gas alone—that is to say nothing of coke—by the Beckton Gas-Works, the Barking super-station would require to have ten times its present maximum capacity. Indeed, the present capacity of the Barking station is no more than the extension required annually by the largest London gas undertaking to meet the normal increase of business. Another point is suggested by the speech of the King at the opening. His Majesty said he was gratified to learn that the difficult problem of co-ordinating the numerous systems of supply within London and the Home Counties is approaching solution; and he trusts the development will spread throughout the country. There is something that ought to have had prior consideration, and that is the co-ordination of the use of the fuels of the country. That is an economic question of pre-eminent importance; but the Government have altogether overlooked or ignored it. His Majesty also referred to the reduction of the smoke of our large towns by the aid of electricity. We are afraid that commodity will not assist very materially in that direction, unless we are to eat with increased velocity into our coal resources. Electricity might claim to do a bit better in that direction if the co-ordination of the use of fuel was something that had materialized into a national system, and some other fuel than raw coal was used partially or wholly for steam-raising.

NATIONAL GAS COUNCIL.

Annual Report.

The following report, together with the statement of accounts, for the year ended March 31 last, having been approved and adopted by the Central Executive Board, was presented to the members at the seventh annual general meeting yesterday.

GAS REGULATION ACT.

Application for Orders, Section 1.—During the period under review six gas undertakings have lodged applications with the Board of Trade for the substitution of a standard or maximum price per therm in lieu of their existing price per 1000 c.ft., and 31 Orders have been made.

Section 1.—*Amending Orders.*—During the period under review, application has been made for a revision of the standard or maximum price per therm granted to gas undertakings under section 1 of the Gas Regulation Act in respect of three undertakings. Although these applications for an Amending Order are usually made by the local authority, it is interesting to note that in some instances an application for a reduction of the standard price has been put forward by the undertakers themselves.

Section 10—*Special Orders.*—During the same period 41 gas undertakings have lodged application under this section with a view to extending the powers conferred by their Private Acts and obtaining additional powers. It will be remembered that proposals were made in the House of Lords last year for altering the expeditious and inexpensive method of procedure prescribed by section 10, and that the Council took active steps to prevent a change of procedure as being a retrograde step and inimical to gas undertakings—particularly the smaller ones. The dissolution of Parliament in November caused the Select Committee of the House of Lords who were considering this question of procedure to cease its functions; but the present Government have restored the Committee, the terms of reference and the membership being practically as before. This Commitee received the views of the National Gas Council on the subject several months ago, the gist of which was that the existing system is eminently satisfactory. Small undertakings, in particular, could not bear the cost of parliamentary contests; and it is hoped and believed that the Select Committee will not materially disturb the existing procedure.

PUBLIC UTILITY COMPANIES (CAPITAL ISSUES) ACT, 1920.

Members were reminded of the forthcoming expiry of the above Act on May 20 this year, and as a doubt had arisen as to the correct legal interpretation of sub-section (2) of section 2 of the Act, Counsel's opinion was taken on various points that were not quite clear, and circulated to all members who were operating under a "consent" obtained under the Act in question. Members were also advised, if they were still in doubt as to their position after the expiry of the Act, to consult their own legal advisers at the earliest possible moment, in view of the situation that would be created after May 20.

LONDON TRAFFIC ACT, 1924.

The Council carefully watched the progress of this Bill, which received the Royal Assent on Aug. 7 last, and secured a number of

important amendments at the Committee Stage. The Act, as passed, ensures that earlier notice will be given to gas undertakings of programmes of work proposed by highway authorities than was the case with the original Bill. Opportunities are provided for gas undertakings affected to make earlier representations to the Minister of Transport in regard to such programmes, and generally the Act allows of closer co-operation between highway authorities and public utility undertakings than did the original Bill.

The officers of the Council attended a conference convened by the Minister of Transport on Feb. 23, with reference to the working of section 4 of the Act. An explanatory letter was sent to all gas undertakings likely to be affected by the London Traffic (Closing of Streets for Works) Order, 1925.

Factory and Workshop Act, 1901—Chemical Works Regulations, 1922.

The illness of the Chief Inspector and Deputy Chief Inspector of Factories caused considerable delay in getting a definite response to the representations made by the Council that certificates of exemption from the above regulations should be granted in suitable cases—particularly in the case of small undertakings.

Certificates of exemption have recently been issued to all the gasworks on whose behalf the Council have from time to time appealed in respect of one or two regulations. These certificates, however, are considered by the Council as quite inadequate; and they have again taken up the matter with the Home Office, and at the same time communicated with all the undertakings who have applied through them for exemption from certain of the chemical regulations, advising them also to write to the Deputy Chief Inspector, protesting that, as at present drafted, these certificates would afford no relief at all to their undertakings.

The Council are still in negotiation with the Home Office.

Mains of Insufficient Capacity.

The Council are glad to report that, after prolonged negotiation, a clause with regard to relief from the obligation on gas undertakings to give a supply of gas where the mains are of insufficient capacity has at last been agreed with the railway companies. Undertakings should, therefore, in the future be able to obtain the insertion of such clause in their Private Bills or Special Orders without difficulty.

Standard Cookers.

The Council have reported to all the members that the Parkinson Stove Company, Ltd., and Messrs. R. & A. Main, Ltd., are now in a position to accept orders for "Standard" gas cookers in large quantities, at special prices, according to the quantity required.

The Council have circulated a form of inquiry to their members to ascertain the estimated monthly requirements of each undertaking, in order that members may pool their orders, and thereby receive the benefit of the discounts obtainable, however small their individual requirements.

Rating of Machinery.

The Council appointed a Committee to investigate this difficult question, and upon their recommendation decided to give evidence before the Departmental Committee who were considering the matter. The gist of such evidence, which was given by Mr. William Cash, F.C.A., on Nov. 6, was that there was grave danger in dealing with the rating problem piecemeal, and that no satisfactory solution could be reached unless the question of the rating of machinery was dealt with in conjunction with the whole problem. The Committee were urged to recommend no principle in regard to the rating of machinery which would have the effect of so altering the incidence of rating as to affect prejudicially the gas industry.

The Departmental Committee have issued their report, which (although not adopting the recommendations of the Council) does not appear to affect materially the interests of the gas industry.

Mains and Cables in Highways.

The Council have been indefatigable in their efforts to protect the members against the endeavours of highway authorities to encroach upon the statutory rights of public utility undertakers in this connection.

The joint conference of representatives of gas, water, tramway, and electrical interests convened by the Council has on several occasions considered this subject at length. A comprehensive memorandum on the question has been prepared and circulated to members. The joint conference decided to confer with representatives of the County Councils' Association, the London County Council, and other bodies representing highway authorities, and such meeting is to be held on May 7, under the chairmanship of Sir Henry Maybury, Director-General of Roads.

Heavy work has also been entailed in advising and assisting individual undertakings in connection with claims put forward by highway authorities. County Councils have, in pursuance of their avowed policy, endeavoured to force undertakings to accept protective clauses in favour of county councils in their Private Bills or Special Orders. So far the efforts of the Council in resisting these claims have been crowned with success.

Railway Companies' Bills—Protective Clauses in Favour of Gas Undertakings.

The Council carefully examined the Railway Bills which were being promoted by railway companies this session, and wherever proposals appeared which were likely to affect a gas undertaking, the Council immediately communicated with the undertakings concerned, warning them of the dangers involved.

A joint conference of the Associations representing the gas, water, tramway, and electrical interests was convened by the Council to consider this question. This conference approved the substance of a draft standard clause prepared by the Council's Parliamentary Agents (Messrs. Dyson, Bell, & Co.) for insertion in Bills promoted by railway companies for the purpose of protecting public utility undertakings. Steps were being taken to obtain the insertion of this clause in Railway Bills introduced this session. Such Bills, however, were withdrawn. Consequently no opportunity was given for pressing the matter. The way, however, has now been paved for suitable action when Railway Bills are introduced in the future.

Proposed Government Financial Assistance to the Electricity Supply Industry.

This all-important question has received the closest attention of the Council. Appropriate communications were sent to Mr. Ramsay M'Donald and other Cabinet Ministers in the Labour Government, and a similar course has been adopted with Mr. Baldwin and the members of the present Government. The Council also set-up a Special Committee to investigate the whole question in all its bearings. The recommendations of this Committee have been carefully considered and approved by the Central Executive Board. The Parliamentary Committee of the Council have been appointed a Committee of Action, and will direct the campaign which is being undertaken to ensure that the views of the industry receive every consideration.

Members of the Council have been supplied with a full statement of the case against any scheme of State-aid for the development of the electricity supply industry.

Tar.

Serious consideration has been given by the Council to the question of promoting the sale of tar for the purpose of road making and road surfacing, and also to the question of countering the incessant and insidious propaganda which is being undertaken by other interests in this respect.

A Committee was appointed to investigate the subject, and steps have been taken to raise the necessary funds for publicity purposes. The Council also decided to take space in the Chemical Hall at Wembley for an exhibit of "British Tar for British Roads." The design for the stand has been executed by the well-known artist Mr. Norman Wilkinson. An expert has been engaged to take charge of the exhibit. Steps will be taken to ensure that the road surveyors of the country, and others who may be interested in the subject, will have an opportunity of seeing what is confidently expected to be a very attractive exhibit.

The Council have received evidence that the sale of prepared tar for road construction and road maintenance was injured considerably by the issue of an unfortunate and misleading circular of the Ministry of Transport, which was likely to be interpreted as meaning that washings from tarred roads were injurious to fish-life, whether the roads drained directly into fishing waters or not. The Joint Managers interviewed Sir Henry Maybury on the question; and, while receiving certain assurances (in themselves not unsatisfactory), were not successful in inducing the Ministry to issue a further circular explaining the true position.

Fixing of Geysers.

The Council have issued during the year a booklet of instructions for fixing geysers, intended for the use not only of gasfitters employed by gas undertakings, but of individual firms who undertake such work. This booklet has had a very good reception in the Press; and judging by the number of orders received from all parts of the country, its publication is widely appreciated.

Some difficulty has been experienced during the year in regard to the regulations of the Metropolitan Water Board regarding water supply to geysers. These regulations, which date from the year 1872, are no longer appropriate to modern practice; and steps are being taken with a view to having them amended in accordance with the specification issued by the Ministry of Health early in 1924.

Report on Carbon Monoxide.

The report to the Board of Trade by Mr. Butterfield, one of the Gas Referees, on the subject of "Carbon Monoxide in Public Gas Supplies," was published last July, and the Council appointed a Committee to consider the recommendations contained in this report.

This Committee held joint meetings with representatives of the Society of British Gas Industries (being makers of gas appliances), in accordance with the undertaking given by the Council to the Board of Trade in the letter appearing as an appendix to Mr. Butterfield's report, "with a view to submitting to the Board of Trade effective proposals, if such can be devised, for discouraging (and, if possible, preventing) the sale of undesirable types and qualities of fittings and appliances and the fixing of geysers and similar appliances without adequate and trustworthy means of ventilation—it being borne in mind that a great many gasfittings and appliances are not supplied by gas undertakings, but by firms over whom they have no supervision or control."

A questionnaire was dispatched to members, asking for the fullest possible information with regard to existing systems of inspection of piping, fittings, and appliances in dwelling-houses.

A Joint Sub-Committee from the Council and the Society of British Gas Industries was formed with the object of preparing a draft specification regarding the quality and size of piping to be used in gas installations.

The question of inspection of piping, fittings, and appliances is also being considered. Reports on these matters will be submitted to the Central Executive Board for consideration.

Instructions regarding the proper methods of fixing geysers have been widely circulated; and close attention is being given to the question of the elimination of undesirable types of apparatus.

Exhibitions.

British Empire Exhibition, 1924.—The Council lent their patronage, and gave financial assistance, to the highly successful Gas Exhibit at Wembley last year. The Council also took part in the World Power Conference which was held at Wembley in June-July of 1924. The gas industry was well represented by a Gas and Fuel Section, and some very interesting papers were read by representatives well known in the gas industry.

Smoke Abatement League of Great Britain—Manchester Confer-

ence.—The Council also were patrons of this Exhibition and conference, which was held in the City Hall, Manchester, in November last, and five delegates from the Council represented them at the conference in question.

District Executive Board.

The Council again tender their thanks to the District Executive Boards, Management Committees, Chairmen, and District Secretaries for their valuable help during the period under review.

Co-operation.

The Council have continued their policy of co-operation with other public utility associations with kindred interests, and much good work has been accomplished by joint conferences with these bodies. The British Water-Works Association have co-operated with the Council in more than one matter of importance to both the industries concerned; and this is only one of the many instances that could be cited which show the value of joint effort.

General.

There are innumerable other matters in connection with which the Council have taken steps to promote the interests of the gas industry or those of some individual undertaking.

Pressure was brought to bear upon the Port of London Authority, with the result that a further reduction was made in February in dock dues. This means that gas undertakings will have to pay less for coal passing through the Port of London.

Again, gas undertakings have been advised from time to time as to the eligibility of proposed schemes of work submitted by them to the Unemployment Grants Committee.

The scheme of workmen's compensation insurance inaugurated by the Council has worked very satisfactorily, and has resulted in premiums being quoted for this particular risk at a considerable reduction upon those quoted by the tariff companies. Two firms of insurance brokers are at present operating this scheme in respect of an increasing number of gas undertakings.

A Conjoint Committee with the Tramways Association, the British Water-Works Association, and the Incorporated Municipal Electrical Association have dealt successfully with several cases where borough accountants or treasurers have endeavoured to transfer from trading departments to their own supervision matters relating to wages, accountancy, collections, control of stores' accounts, &c.

The interests of the gas industry have been carefully watched with regard to the inquiry into the Standard Revenue of Railway Companies, and it is satisfactory to all traders that the appeal of the Railway Companies against the judgment of the Railway Rates Tribunal with regard to the computation of the standard revenue of the railway companies did not succeed.

Counsel's opinion has been taken in the past twelve months with regard to a new basis of assessment suggested by a well-known rating surveyor in the case of certain gas companies who were members of the Council; and it is extremely satisfactory to report that the figure finally agreed in these cases was a considerable reduction upon the original figures, which were the outcome of such computation.

The Council are at the present time engaged also in moving the necessary amendments to the Roads Improvement Bill and the Public Health Bill, 1925, and are submitting evidence before the Committee of the Board of Trade to inquire into British Trade and Industry.

That the Council's efforts on behalf of their members have proved of avail in more than one instance is borne witness to by letters received expressing appreciation of advice given and assistance rendered.

Income.—The total amount received by the Council by way of joint subscription to the National Gas Council, the British Commercial Gas Association, and the Institution of Gas Engineers (for research work) during the period under review amounted to £58,013, of which sum £16,642 is retainable for the purpose of the National Gas Council.

To the above figure of £16,642 there must be added interest on deposit account and payments by manufacturers in respect of sales of the Council's "Standard" gas cookers—viz., £232 and £241 respectively—making a total of £17,115, of which £1038 has been carried forward (being the proportion of subscriptions paid in advance) to meet the expenses which will be incurred during the financial year 1925-26. The income of the National Gas Council in respect of the year ended March 31, 1925, including the amount of £1732 brought forward from the last account, is therefore £16,909.

Expenditure.—The expenditure of the Council for the past year amounted to £16,882. The surplus on the year's working is therefore approximately £27, which decreases the accumulated deficit at the date of the last account to £2228.

Reserve Fund.—Of the sum of £1300 shown in the last account, as the balance of the reserve for the purchase of furniture and fittings for the Council's offices, at No. 28, Grosvenor Gardens, and for the expenses in connection with the acquisition of the premises in question, £234 has been expended for the purpose of additional office equipment, leaving a balance of £1066.

Membership.—The total number of undertakings subscribing to the funds of the Council at March 31, 1925, was 841, representing 88 p.ct. of the total make of gas in the United Kingdom.

D. Milne Watson, *President.*
W. J. Smith, *Secretary.*

May 12, 1925.

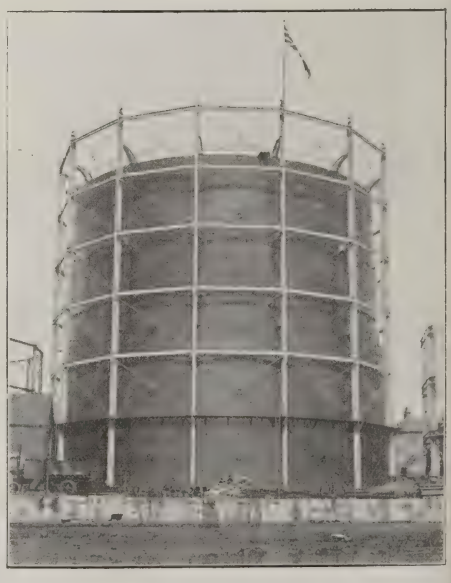
NOVEL GASHOLDER EXTENSION AT WEYMOUTH.

The difficult problem of increasing the capacity of a gasholder while still keeping it available for immediate service has been successfully solved at Weymouth, where a third lift has recently been added to a large gasholder without removing the gas, and under conditions that permitted the holder to be at call for use upon the district at any time during the progress of the extensions. The gasholder is a guide-framed one in a steel tank 100 ft. diameter; and the scheme by which the capacity was increased by 50 p.ct. while still keeping it in commission was devised by the Company's Engineer, Mr. J. T. Joyce, in collaboration with Messrs. Samuel Cutler & Sons, Ltd., who carried out the contract.

The guide-framing was first strengthened and heightened to the extent of the travel of the extended gasholder, and then the new lift was built around the existing second one (while still inflated with gas), from which it was temporarily suspended. The two-lift holder was therefore free to function in the ordinary way, but carried as a passenger the new lift nested round its circumference, first in skeleton form and finally in fully-sheeted condition. Considerable ingenuity was necessary in substituting below water level new cup carriages for the old displaced bottom rollers; but this and many other obviously difficult details were successfully negotiated without the least hitch, and the entire extension was completed in less than contract time.

The handing-over of the holder to the Company was made the occasion of a gathering at the gas-works on May 16, when the Mayor of Weymouth and many prominent townsmen made an inspection of the works.

At the subsequent luncheon, the Deputy-Chairman, Mr. S. S. Milledge, who presided in the absence abroad of the Chairman, Mr. Mark C. Frowde, gave a most interesting account of the history and present extensive operations of the Company, and highly complimented both the Engineer and the contractors (who were represented by their Chief Staff Engineer, Mr. W. T. Palmer) upon the successful completion of a notable example of gasholder engineering.



The Completed Holder.

University of Michigan.—From Prof. Alfred A. White, of the Chemical Engineering Department of the University of Michigan, we have received a copy of the annual Bulletin descriptive of the Course in Chemical Engineering, which can be obtained on request from the University authorities. The Department was established in 1897; and the present Head, Prof. White, who has been a member of the Department since its founding, has contributed significantly to its development. A new building was completed and occupied about a year ago, and is excellently equipped for teaching chemical engineering. The technique is taught through two courses. The first group—the preparatory group—is common to all engineering work at Michigan; while the second includes the special studies that constitute the professional courses in chemical engineering.

THE GAS EXHIBIT.

Every day sees some little addition, some finishing touch, o one or another of the beautiful parts which go to make up he Gas Exhibit at Wembley; and it is gratifying to learn that oth the attendances and the interest are maintained.

The demonstrations of Empire Food given in the Cookery Hall are proving very popular, and the audiences are growing is what is to be seen and heard becomes more widely known. The demonstrations take place four times daily—at 11.30, 2.30, , and 6.30—and every class of food is dealt with. There are omplete meals of several dishes, with hot and cold sweets. The people who attend show themselves most interested, and are of every class. As a matter of fact, quite a few would appear to spend the whole of their time in the Cookery Hall. They are evidently keen on gas cooking; and though this method has been in use for so long, and is now so general, astonishment is still expressed by some people on finding out how much can be done with the gas cooker. Talks on Empire food form a prelude to the demonstrations.

Good Lighting.

The lighting of the General Exhibits Hall, the Cookery Hall, and the Empire Food Hall attracts much attention. It is carried out by a series of ten-light outside type suspension lamps, which have been rendered most effective by the addition of really artistic silk shades. The lighting is well diffused; and the arrangement affords a good example of illumination for large halls.

Fruit Bottling and Jam Making.

Live Exhibits.

The value of the "live" exhibit is well exemplified by the fact that the gas-heated wafer-baking machine is a constant source of attraction to the people passing through the Palace of Industry.

Another feature of interest in the exhibit is the laundry, which is fitted with a live "Gladiron." The "Gladiron" itself is rather a big affair, weighing about 90 lbs.; but this need cause the manipulator no anxiety, for it is moved over the board by electricity in so easy a manner that anyone could use it. The iron is heated by high-pressure gas, provided by a small compressor. The laundry is fitted with hot water apparatus, ordinary domestic irons, a clothes airing cabinet, and a washer.

Cool Corners.

Which is the coolest and most restful spot for the tired visitor at Wembley? The "heat wave" of the past week urged sightseers to a solution of this problem; and the verdict seemed to be: "Within the Palace of Industry." One visitor said that his tired feeling speedily vanished as he reclined in one of the luxurious lounge chairs provided by the Gas Exhibit, and gazed on the cool marble of the charming Indian bathroom with its sunk bath. His companion voted for the near-by gas-ammonia machine, which will freeze a quart of ice cream or a variety of drinks in a few minutes, and to which reference was made in last week's "Journal." The Cookery Hall naturally appeals strongly to women in need of a rest; and it possesses the advantage of having ample accommodation for the youngsters.

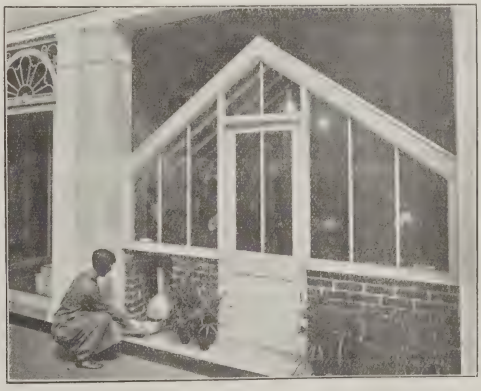
There appeared in "The Times" Empire Day Number, last Saturday, under the title of "Gas in the House and Workshop," an article in which the writer refers to the early investigations of Dr. John Clayton, and adds: "One wonders what would be the feelings of this pioneer could he inspect the British Empire Gas Exhibit in the Palace of Industry, and see the wonderful developments which have taken place in the inter-

Domestic Laundry, showing 90 lb. Patent High-Pressure Iron.

vening centuries." A description of the display follows; it is remarked that "credit must be given to the organizers of the Gas Exhibit for the artistic method they have adopted of revealing the complete story of the utilization of gas."

The "Quead" Gas Cooker.

Messrs. Wm. Geipel & Co., of Vulcan Works, St. Thomas Street, London, S.E., are showing in the Palace of Transport the "Quead" gas cooker, which roasts, toasts, grills, &c., by radiant heat applied simultaneously to both sides of the food. Baking, broiling, and plate warming are done in an oven above, with a separate door, by waste heat rising from the griller. For this apparatus are claimed "novel methods which create an entire revolution in modern family cooking." The griller and roaster consists of two vertical radiators, which are arranged opposite to each other and are adjustable, either nearer or further apart. Self-centring foodholders are provided to take chops, steaks, bacon, fish, toast, &c.; while for roasting there is a centrally supported meat hook, from which a joint or fowl may be hung. The hook is slowly revolved, by means of a substantial clockwork motor fitted to the outside of the oven There is said to be economy in the quantity of gas consumed as compared with an ordinary gas oven.



Greenhouse, showing Gas Heater Fitted Outside.

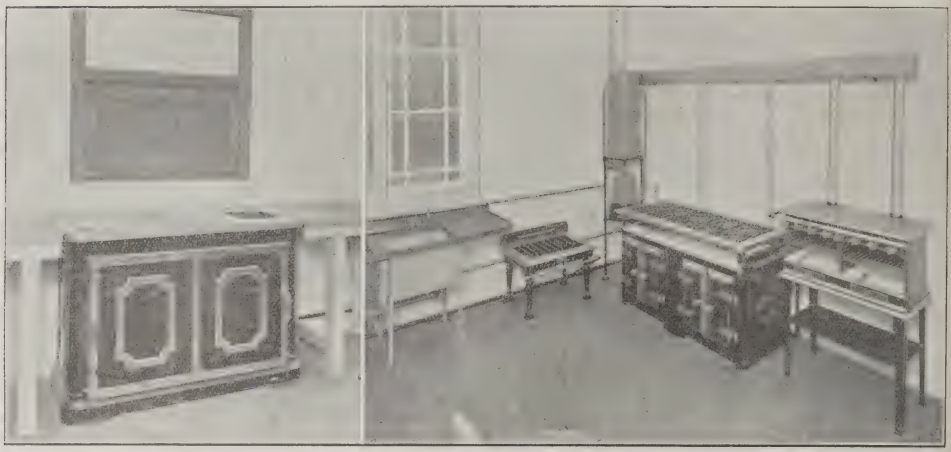
"Corolite" Concrete Mixture.

Among the various uses of concrete mixtures for housing schemes, mention has been made of the system of Corolite Construction, Ltd., of Goschen Buildings, Nos. 12 and 13, Henrietta Street, London, W.C. In an article which appeared in "The Times" some time back, on the housing display, Sir Lawrence Weaver made the following reference to this method

of construction: Among the most promising of the new concrete mixtures is that known as Corolite, "which in Holland and elsewhere has stood the test of many years' weathering. The broad idea of this mixture is indicated by its name. The type of aggregate and the method of mixing provide a wall substance well furnished with a system of internal cavities, so that the most violent beating of rain is said not to cause any passage of damp through the thickness of the wall. So effective is this barrier of air passages claimed to be, that builders in Holland have even abandoned the normal precaution of a damp-course, as moisture seems unable to arise through the wall from the foundations."

A "MAIN" GAS KITCHEN AT WEMBLEY.

Specially Installed for Civic Hall Banquets.



[*Photo. Campbell Gray.*

VIEWS IN TH KITCHEN EQUIPPED BY MESSRS. R. & A. MAIN.

Visitors to Wembley last year will recall the large Civic Hall, which during the run of the Exhibition was taken, for a week or so at a time, by one large town or another in the country for the purpose of drawing attention to special local industries, advantages of a district from the point of view of manufacturers, attractions for visitors, &c. For such a purpose the hall itself is admirably suited; but the lack of suitable kitchen arrangements was felt to be a considerable drawback. Therefore, in preparing the hall for a similar set of engagements this year, it was determined to remove the reproach that a first-rate civic banquet could not be prepared on the spot. Messrs. R. & A. Main, of Gothic Works, Angel Road, Edmonton, were approached on the subject, and have fitted up a kitchen with apparatus which will delight the most exacting chef. Different municipalities will bring their own staffs; but all will be able to produce the most perfect results in this convenient and absolutely self-contained kitchen, which is designed throughout for the very best class restaurant work.

The service has been arranged conveniently along one side of the kitchen—one part to receive through a hatchway dirty plates and dishes, and waste material which can be dropped through a hole into the bin below; the plates and dishes being then passed to the right for washing. There are separate hatchways for receiving and handing out; and both can be closed if necessary. There is a partition between the handing-out side and the receiving side, to prevent any possible contamination of the food being served by the dirty crockery as it is handed-in.

The Gas Apparatus.

On the left-hand side of the service is a gas hot closet, on which meat, poultry, &c., is carved up and kept hot while being handed out. In addition, of course, to serving as a carving table, plates and dishes are warmed and kept hot in the closet, which is provided with the usual sliding doors. There are two carving wells, with removable tinned copper linings, which are easily cleaned and handled; and on the top there is a bain-marie, for keeping sauces, &c., at the required temperature.

On the other side of the kitchen, one is struck first by the excellent appearance of the gas cooker—which takes the form of a Main "Duke of York" double-oven range, each oven having double doors, and being packed, and lined with enamelled steel sheets. The convenience of the double oven is that one can be used (say) for pastry, while another is required to be at a different temperature for roasting. The hotplate is fitted with the very latest "Efficiency" type burners; and everything about the cooker is designed for easy cleaning and convenient service.

Next to the cooker is a double-compartment grill, with porcelain enamelled fat collectors. Here, again, one compartment can be used for grilling steaks, &c., while the other may be toasting bread or scones.

On the other side, is a stock-pot stove, with one large double concentric ring burner; each ring being controlled by a separate gas cock.

Plenty of hot water for washing purposes is provided by one of the firm's "Energy" circulating water heaters, fitted with automatic thermostatic control valve, and connected with a 20-gallon tank.

All the gas apparatus is provided with flues passing direct to the outside atmosphere.

The size of the kitchen, and the cooking capacity it was required to provide, called for careful planning to secure the greatest advantages. This it received; and Messrs. R. & A. Main have provided a well-selected set of modern apparatus which will be the admiration of all who are called upon to work with it.

Green Gasholders.—In Denver gas distribution has been developed largely on the system of district holders; and these holder stations are in the residential sections. Under the Doherty Ideal Distribution System (the one adopted) it is essential that the district holders should be located at load centres, which, in a city using gas for practically all domestic purposes, will be in residential areas. Mr. Wallace L. Thackrey (of the Public Service Company of Colorado), in the magazine of the American Gas Association, explains that, in the first place, care is taken to purchase sufficient land, so that the general lay-out does not look crowded. The holders themselves are surrounded by trees, which, when a few years older, will be quite tall and full of foliage, thus hiding to a large extent the holder. The holder is painted green, the shade of which matches that of the tree foliage, thus eliminating any unattractive spots or patches which would otherwise be visible through holes in the foliage. Members of the Midland Association of Gas Engineers and Managers who were fortunate enough to take part in the recent visit to their President at Oxford, will recall the pleasing effect, upon which Mr. Caton was heartily congratulated, of painting green a holder erected in a rural situation.

HORLEY DISTRICT GAS COMPANY (ELECTRICITY SUPPLY) BILL.

A Retrograde Step.

The gas industry will learn with surprise and disappointment that this Bill, which, after a searching inquiry, was passed by the Earl of Clarendon's Committee in the House of Lords, has been rejected in what may well be termed a casual manner by a Committee in the House of Commons. This disappointment will be shared by all who have the Nation's welfare at heart; for the passing of the Bill would have constituted an important and rational advance along the path of progress towards a reasonable method of utilizing our fuel resources. In this country electricity cannot, by the very nature of things, hope to supplant gas in many fields—notably those of cooking and heating. At the same time there are definite requirements which electricity can satisfy well. What is needed, therefore, is a recognition of the limitations of electricity, and, following this, a go-ahead policy based on public service. No better method of producing cheap gas and cheap electricity exists—and at present this applies particularly to rural districts—than by centralization of gas and electricity supply at one station; and this procedure, because it is essentially non-wasteful, is in the interests of the Nation. Co-operation is not merely an ideal: it is a practical ideal. That which is at present preventing its yield of fruitful results is insular bigotry. The passing of the Horley Bill would have helped to break this down; as things are, its rejection will serve to strengthen it.

Electricity Commissioners *v.* Parliament.

It is unnecessary to go into the details of the Horley Bill, for the proceedings before the House of Lords have already been dealt with in the "Journal," and an account of those before the House of Commons Committee is published in later columns of this issue. To put the matter in a nutshell, however, and to emphasize the injustice of the latter Committee's decision, it may be stated that, so long ago as last June, the Horley Gas Company gave formal notice to the Electricity Commissioners that powers to supply electricity were to be applied for; and similar notice was given to the Board of Trade. In July, however, in view of the uncertainty with regard to the passage of Mr. Clarry's Bill, they passed a resolution to promote a Bill, and added that the Commissioners be informed. This was followed-up subsequently, it appears, by sending the Commissioners a copy of the Bill on the same day as it was deposited in Parliament. In October the parliamentary notice of that intention was published. In October, also, the Horley and District Electricity Supply Company, Ltd., were registered, and applied to the Electricity Commissioners for an Order empowering them to supply. The Electricity Commissioners held no inquiry, but in January, 1925, made an Order in favour of the Electricity Company. This fact certainly seems to indicate that the Electricity Commissioners held strong views of their own as to whether the Gas Company should have even a chance of succeeding; and the hearing before the House of Commons Committee developed into a contest between the Electricity Commissioners and Parliament. Unfortunately the former prevailed, owing, it may confidently be asserted, to the strong declaration of the Commissioners' policy by Sir Harry Haward himself, referred to later.

Arguments of the Opposition.

The main argument of the opposition was that competition between gas and electricity is a desirable—even a necessary—factor. Whatever the strength of such an argument as applied to a large industrial area, it has been proved that in a district like Horley it is in the public interest to have a combined supply. Every point put forward by the Gas Company was advantageous to the consumer. The same overhead charges and administrative expenses, the fact that cheaper capital could be raised by the Company, restriction of dividends, certainty of supply within twelve months—all these favoured the consumer. It was suggested by the opposition that, whereas the Electricity Company had a strong incentive to effect economies and reduce the price, in order to increase business, the Gas Company had not, because increases in the sale of electricity would to some extent be at the expense of gas. While the gas undertaking was operated under the sliding-scale, no such sliding-scale was attached to the electricity undertaking. To satisfy any qualms on this score, the Gas Company made a proviso to the effect that the Electricity Company should have the same power of revising prices and method of charging as they have in an Order. As to the bogey of competition, it was suggested by Sir Harry Courthope-Munroe that the House of Commons Committee should give the Gas Company their Bill, and then let the Ministry of Transport, if they thought fit, pass the Order also. There would then be the highest cut-throat competition in Horley. Of course, a good deal was said, towards the close of the hearing, of the bulk supply of electricity from the Barking station of the London County Electricity Company; but the Gas Company were entirely willing to take this supply, and, indeed, had a large potential consumer in the Sussex Electricity Supply Company, Ltd. In spite of all this, however, the Bill was rejected.

Mr. Clarry's Bill.

The Horley Bill has brought out the general view of the Electricity Commissioners in regard to Mr. Clarry's Bill, which, according to Sir Harry Haward, is that there may be cases where it is right that the supply of electricity should be entrusted to a gas company, because it may be the only means by which a district can get a supply. *"The prospects may be so poor that nobody except the gas company may be able to deal with the situation."* The Commissioners say that on general grounds it is preferable that the supply of electricity should be in the hands of the body whose sole duty is this supply. In other words, assuming that Mr. Clarry's Bill is passed, gas companies will have their case adjudicated by a prejudiced tribunal. They will be left with the crumbs which fall from their master's table. This is a highly disagreeable state of affairs.

SHORT BIBLIOGRAPHY OF COKE.

Compiled by H. J. Hailstone, A.M.I.Chem.E.

Interest in coke, its properties, manufacture, and use, has been stimulated by the competition organized by the "Gas Journal," at the instigation of Sir Arthur Duckham; and doubtless many intending competitors will have made searches into the literature of the subject for data and records of previous investigators. No apology is therefore needed for the publication of the list given below, which bears ample witness to the importance of the subject and the degree of study to which it has been submitted by numerous workers.

Some of the main contributions are here tabulated under general titles which indicate roughly the scope of the subject dealt with; but it must not be forgotten that enormous volumes of data exist under such headings as "Carbonization of Coal," "Gas Manufacture," &c., which might well be included under the heading "Coke." To have included these items in the present list would have entailed a task of indexing that the writer finds at present impossible, and would also prove too voluminous for a single issue of the "Journal."

The main points of earlier work are summarized in the recognized text-books on "Coke;" and for the titles of these (there is a considerable number) the publishers' catalogues should be consulted. The pages of the "Gas Journal" ("Journal of Gas Lighting" prior to 1917) give further testimony to the importance of the subject; and the indexes of former volumes are well worth investigation. Other journals dealing particularly freely with the technology of coke are "Fuel in Science and Practice" (published by the "Colliery Guardian" Company, Ltd., No. 30, Furnival Street, London, E.C. 4), and "Brennstoff-Chemie" (Verlag. W. Girardet, Essen, Germany).

"B.C.G.A." Conference at Harrogate.—Unfortunately it has been impossible to include in this issue the report which is in hand of the valuable conference held last Thursday, under the auspices of the British Commercial Gas Association. It will appear next week.

THE TAR POSITION.

[Communicated.]

The present quotation for tar in this country is 30s. per ton. In May of last year it stood at 50s. per ton.

With prices falling as they are, and stocks increasing, producers would welcome any proposals having for their object the stimulation of sales in such a way as to provide an adequate return for the cost of distillation and its incidental charges. The time is undoubtedly opportune for British tar manufacturers to bestir themselves, having regard to the circumstance that France now urgently needs the commodity they have to offer. It is a fact that, while the mileage of roads in England, Wales, and Scotland aggregates 38,600 (24,000 classified under A, first class, and 14,600 under B, second class), roads in France of various classes corresponding in traffic conditions to the British A and B classes aforesaid, cover a mileage of 40,000. It may be added that the French classification of roads is somewhat different from the British method, as it is based on questions of property.

Now the production of tar in England, Scotland, and Wales for the year 1923 was: From gas-works, 960,000 tons; from coke ovens, 715,000 tons; and from other sources about 25,000 tons—making a total of 1,700,000 tons. In the year 1924 France produced from her gas-works 230,000 tons, and from her coke oven works 190,000 tons—a total tonnage of 420,000, utterly inadequate for her requirements.

Coming to the question of the utilization of tar on roads, in Great Britain, 300,000 tons of prepared tar were sold for this purpose. In France the sale was only 150,000 tons of tar, mostly in its crude state. Prices in France for crude tar in January, 1924, were 350 frs. per ton at the works; in January, 1925, the price was 230 frs. At that date the price of prepared tar was 370 frs. per ton delivered at the works.

On the roads in the Riviera, and on other well-known motoring roads in France, the inconveniences arising from the dust nuisance have become very acute. The French are crying out for road-spraying material to remedy the evil. There are heavy stocks of tar in the stores of her Ally ready for disposal. What can be done to come to equitable terms as between buyer and seller? Are the difficulties insurmountable?

The Comité Central des Producteurs et Distillateurs de Goudron en France, it is believed, would welcome an arrangement advantageous to both parties. Which of them will make the first move to negotiation?

We are well aware that at Wembley special attention is being directed to tar problems, with what effect there has not been sufficient time to show. What is strongly urged is that the potentiality of France as a tar purchaser should at once be recognized, notwithstanding considerations arising from respective values when rates of exchange are taken into account. The views of "Journal" readers on a subject of great commercial interest to both countries are invited.

Installing an Under-Water Gas Syphon.

The Boston Consolidated Gas Company have lately completed the installation, under the Chelsea Creek, East Boston, of a 30-in. cast-iron gas syphon; and as some rather unusual features were involved in the building and placing of it, a description of the work has been contributed by Mr. D. S. Reynolds, the Company's Engineer of Construction, to the pages of the "American Gas Journal." From this it appears that the main supplying East Boston crosses the Chelsea Creek by means of a 24-in. steel pipe from the shore to the vertical leg of the 30-in. syphon; down 55 ft. to the horizontal portion—which is 35 ft. 6 in. below mean low water, and is 150 ft. long between risers—then up about 48 ft. to the 24-in. steel pipe connecting to the East Boston shore. The steel pipe is supported on wooden pile towers, driven into the bed of the creek at distances of about 35 ft. Each tower consists of four oak piles, supporting steel saddles, to which the pipe is rigidly clamped. Expansion and contraction are provided for by means of large flanges flexible enough to allow for the lengthening or shortening of the pipe due to changes in temperature. All joints in the steel pipe are made by bolts, with red lead putty. The 30-in. syphon itself is made of cast iron 1⅛ in. thick. It is pointed out that this thickness was selected to provide a pipe that would be certain to remain sunk—the ordinary weight of gas pipe being able to float if both ends were tightly closed and the pipe filled with gas or air—as well as to afford protection against the effects of corrosion. There is an electrically driven deep-well pump to remove the condensation from the syphon. When the horizontal pipe had been placed safely in position on the supporting piles, the two vertical legs were assembled with poured-lead joints on the deck of a lighter, and the bulkheads in the tops of the drip-trees were removed, allowing the water to fill the pipe. The vertical legs were then lowered, so that the spigots entered the bells of the drip-tees, when a diver made the joints with lead wool, and caulked them with a compressed air driven caulking tool. The syphon was afterwards pumped out, and the two 24-in. steel pipes connected to the vertical risers.

SOCIETY OF BRITISH GAS INDUSTRIES.

ANNUAL GENERAL MEETING.

THE Annual General Meeting and Dinner of the Society took place in the Hotel Cecil, London, W.C., last Wednesday, under the Presidency of Mr. D. MILNE WATSON, D.L., M A., LL.B., who delivered his address.

MINUTES OF LAST MEETING.

The minutes of the previous annual general meeting were taken as read, and signed.

The SECRETARY (Mr. Arthur L. Griffith) said unfortunately Mr. J. Wilfrid Drake (the Chairman of the Council) was unable to be present; and the following cablegram had just been received from him:

s.s. "Leicestershire," Lisbon.

Please ask President tender my congratulations to new President, Chairman, and officers, and also express to all members my appreciation and thanks for their kind assistance and co-operation during my year of office. Wish you successful and enjoyable meeting.—J. WILFRID DRAKE.

Alderman Fred J. West (Lord Mayor of Manchester) was prevented from attending by an important Council meeting; and Prof. Arthur Smithells had written:

I am extremely sorry that I shall not be able to attend the annual meeting or the dinner. I particularly regret my absence on this occasion. I have been in the surgeon's hands, and after six weeks of nursing home am now in the convalescent stage. I am getting on very well; but, of course, it takes time to recover after this kind of ordeal.

Please convey my regrets.

ARTHUR SMITHELLS.

He had also received other apologies for absence.

On the proposition of the PRESIDENT, it was agreed that the following telegram should be dispatched to Prof. Smithells:

The Society of British Gas Industries in general meeting much regret that you are unable to be with us to-day, and send best wishes for your speedy recovery.—MILNE WATSON, President.

REPORT OF THE COUNCIL.

The CHAIRMAN then presented the nineteenth annual report of the Council, on the work of the Society during the year 1924-25. It was as follows:

We have to record the death of the following members:—

William H. Tilley, of the firm of Tilley Bros.

J. G. Stewart, Chairman of Stewarts and Lloyds, Ltd.

The Society wishes to offer its congratulations to the following gentlemen:

Sir Dugald Clerk, K.B.E., who has been awarded a Royal Medal of the Royal Society for his application of scientific principles to engineering problems, particularly to the development of the internal combustion engine.

The Rt. Hon. Sir Henry E. Duke, on the Peerage conferred upon him by His Majesty the King under the title of Lord Merrivale.

Alderman Fred J. West, C.B.E., on his election as Lord Mayor of Manchester.

Institution of Gas Engineers.—We learn with much pleasure that the Lord Mayor of Manchester has been nominated for election as an honorary member of the Institution at their annual meeting in June.

British Empire Exhibition, 1925—Gas Exhibit.—Members will be pleased to know that very satisfactory arrangements have been made with the Exhibition Authorities not only for having the same prominent position in the Palace of Industry as in 1924, but for additional space, which has been acquired upon very advantageous terms. This will enable the cookery lectures to be given in a separate hall, and so prevent their being interfered with by noise and movement, as was the case when they were delivered in the Second Hall last year. Arrangements have also been made, upon the suggestion of the Empire Food Committee, for lectures and demonstrations to be provided and our hall used to bring food subjects before the public. There will now be proper office accommodation; and a drawing room has been placed at the disposal of women journalists for rest, writing, rendezvous, &c., at the suggestion of Lady Burnham, on behalf of the Society of Women Journalists. It thus appears likely that the Gas Exhibit will this year be a greater centre even than before for propaganda on behalf of gas. The increased space provided has allowed a greater number of exhibits to be shown. The British Empire Exhibition Committee have awarded the Society a bronze medal in recognition of our co-operation in the 1924 Exhibition.

Gas Safety Committee.—The Society is co-operating with the National Gas Council in connection with the recommendations in Mr. W. J. A. Butterfield's report to the Board of Trade, and especially with regard to the requirements of safe fittings. A Joint Committee has been formed consisting of eight members of each body. It is hoped that good results will emanate from the efforts of this Committee.

Trade Mark "SOBGI."—The registration of the trade mark "SOBGI" has now been completed, and certificates granted by the Patent Office under the following classes:

Class 8.—Gas Meters, Gas Regulators, and Gauges.
" 13—Gas Fittings made of Metal.
" 15—Glass for use in connection with Gas Fittings and Appliances.
" 16—Refractory Material for use in connection with Gas Heating Appliances.
Class 18—Gas Stoves, Gas Ranges, Gas Radiators, for Heating; Gas Geysers and Gas-Heated Water Circulators in the nature of the Stoves.

Retort Setters.—The terms of the Manchester Agreement between Section I. of the Society and the Amalgamated Union of Building Trade Workers expired on May 1, 1924; but by mutual understanding this was continued *pro tem.*, pending a satisfactory conclusion being arrived at regarding an extension of the agreement and the introduction of a new signatory in the Federation of Gas Employers. The new Agreement, which was signed in London on Nov. 13, 1924, is working satisfactorily, and will continue in operation until May 1, 1926. It is hoped that its provisions will remove many anomalies which existed before owing to the difference in rates and conditions between the gas-works' and contractors' employees.

Standard Gas Valve Flanges.—The recommendations of the Joint Committee of the Institution of Gas Engineers and our Society have now been approved, and agreement has been arrived at between the Committee and the British Engineering Standards Association. We understand that particulars of the standard flanges will shortly be published.

Standardization of Medium Size Inverted Mantles.—This matter has been under consideration by the Lighting Section, and a certain amount of agreement has been reached. It is hoped further progress will be made.

Refractory Materials.—Active work is being carried on by the members of the Fireclay Section; and everything is being done to improve the manufacture of refractory materials. Classes have been formed in Stourbridge for workers in the industry, and are meeting with success.

Register of Names of Gas Apparatus.—As the outcome of a suggestion from the Gas Stove Section, a register of names of apparatus has been prepared from the schedules sent in; and in the event of a new piece of apparatus being brought out, the register can be searched by any of the members, to see if the name has been anticipated.

Illumination Committee.—Sub-Committees have been formed by the British Engineering Standards Association to deal with the questions of:

1.—Standardization of methods of testing, and specifying the characteristics of, glassware and translucent materials.
2.—Fittings.

A representative of our Council has been appointed on these Sub-Committees, and we shall give all the support we can.

Revision of Railway Classification of Goods.—Messrs. Tweedy & Holt, of Halifax, have watched our interests at meetings of the Railway Rates Tribunal; and their reports on railway matters are issued in the "Bulletin" and the monthly circular-letter to the members. Among other matters which have been under consideration, and on which action has been taken, may be mentioned:

Board of Trade Inquiry into British Trade and Industry.
National Confederation of Employers' Organizations.
Unemployment Insurance (No. 2) Act, 1924.
Company Law Amendment.
Preferential Tariff Treatment of British Goods in Australia and New Zealand.
Canada—Customs Tariff.
Standardization of Contract Conditions.

Smoke Abatement Exhibition—Manchester.—The Society gave its patronage to this exhibition, which was held in Manchester in November, and was represented at the Smoke Abatement Conference in connection therewith.

British Commercial Gas Association.—The propaganda work of the Association, especially in connection with the Gas Exhibit at Wembley, is proving beneficial to all engaged in the gas industry. We congratulate the Association on its very successful annual conference in Liverpool, at which a number of our members were present.

University of Leeds—Celebration of Coming of Age and the Jubilee of the Yorkshire College.—The Society was represented at the celebrations in December last in connection with the Coming of Age of the University and the Jubilee of the Yorkshire College.

Quarterly Bulletin.—The Council have felt that the "Quarterly Bulletin," while doing very useful work, was too intermittent to be of real service by keeping our members in close touch with the work of the Society; and we have decided that only two half-yearly issues—one after each of our general meetings—shall be retained, which will contain full reports of our meetings in the spring and autumn. Circular-letters will be issued after each monthly Council meeting, so that the members will be kept in touch with matters which are being dealt with. They trust their efforts in this particular direction will be appreciated, and that the more frequent communication with the members will tend to a greater interest being taken in the Society, and to cement the individual interests for the benefit of the industry.

Membership.—The membership of the Society is steadily increasing; some additional firms having recently become members.

City and Guilds of London Institute.—The prizes in connection with the City and Guilds of London Institute's examination in gas engineering, gas supply, and gasfitting have been duly awarded and announced in the Technical Press.

Visit to Manchester.—The April meeting of the Council was held in Manchester, when the members were welcomed by the Lord Mayor, who afterwards entertained them to luncheon at the Town Hall.

The Council take this opportunity of according their best thanks to Alderman West for his kindness and hospitality.

Presidential Badge.—A handsome badge of office, to be worn by our President, was presented during the year by Mr. J. Wilfrid Drake, Chairman of the Council; and our President was invested with it at the autumn general meeting.

The Presidency.—The Society wishes to accord its best thanks to Mr. D. Milne Watson, D.L., M.A., LL.B., for his valuable services during his presidency. On his retirement he has been pleased to accept the office of a Vice-President; and we hope that we may long have the benefit of his counsel and advice. We also desire to place on record our best thanks to the Rt. Hon. Lord Weir of Eastwood for his able address at the last annual meeting; also to Mr. J. Wilfrid Drake, Chairman of the Council, for his paper at the autumn meeting entitled "Some Aspects of the Metric System," which led to a good discussion. The Council have much pleasure in announcing that the Rt. Hon. Sir Alfred Mond, Bart., M.P., has accepted the presidency of the Society for the coming year.

On behalf of the Council,
J. Wilfrid Drake, *Chairman.*

The Report Adopted.

Mr. B. B. Waller said that, in the absence of the Chairman, it fell to him to move the adoption of the report. He thought they might congratulate themselves upon the varied number of matters that the report embraced. Members would appreciate that the Council had had a fairly active year, with the diverse subjects that had come before them for review. In glancing over the report for the previous year, he noticed that a prominent subject on that occasion was their new offices. They were firmly established there now; and the more they saw of them the more they liked them. They did the Society great credit, and yet not greater credit than was due to an organization of their standing. It was, however, felt that perhaps a little more use might be made of these offices by the members in general; for at the present time they seemed to be utilized almost entirely for the Council meetings. It was open to all the members to make use of them. Another matter to which he would allude was that of Sectional meetings. It was felt that a little more zeal and interest might be shown in calling meetings of the different Sections, which would be profitable to all concerned.

Praise for the Gas Exhibit.

Reference was made in the report to the British Empire Exhibition, 1925. When the question of a gas exhibit there was first brought before the Council, there was, perhaps, some little divergence of opinion—more particularly between the Heavy and the Light Sections—as to whether a repetition of the gas exhibit would be desirable. However, the members of the old Exhibition Committee of the Council had an opportunity of meeting the members of the National Gas Council; and the feeling at that meeting was overwhelmingly in favour of repeating the gas exhibit at Wembley this year. After that view had been expressed, he thought it would be the unanimous opinion of the members of the Society that the exhibit should be repeated, in view of the highly satisfactory results secured last year. Those of them who had already visited Wembley, and seen the new exhibit, would agree that the decision arrived at had been a wise one. The exhibit was a remarkable piece of work, and reflected great credit on the Gas Exhibit Committee and all concerned. Their best thanks were due to Mr. F. C. Tilley, their late Chairman, for his untiring efforts, and the very great interest he had taken in the matter of this gas exhibit. He understood from Mr. Tilley that, if possible, the spirit of co-operation between the various bodies who had been responsible for the gas exhibit had been even more strongly evinced this year. They believed that the cost of the exhibit this year might be round about one-half of what it was last year; and the Society were hoping that their members would subscribe in proportion to what they did on the previous occasion, and so maintain the good opinion that was formed last year of the assistance they gave to the exhibition from a monetary point of view, over and above the part they took in supplying material for the exhibit.

"A Very True Advertisement."

Personally, his opinion with regard to the exhibit was that it was bound to be a very fine advertisement for them. In this connection, he sometimes thought of what their old friend the late Mr. Walter King used to say to him: "When times are bad, advertise freely; and when times are good, do what you like about it." Mr. King believed strongly that when things were bad they should extend their advertising. Well, they could not say at the present time that things were good in the country. Trade was difficult, and orders were scarce; and he felt that this gas exhibit at Wembley was going to be of very great service to them.

While on this subject of the gas exhibit, he was reminded of the other side—the electrical side. They had all been struck by the extraordinary obsession of politicians of all parties at the present time—that electricity was the only thing to improve this earth, and that there was nothing to compete with it. However, he had just glanced at the President's address, and he saw this matter was very fully dealt with there; so he would say no more about it. It was mentioned in the report that the trade mark "SOBGI" was now registered. He saw that the classes to which it applied were more or less limited; but he thought it was going to be of very great service to the makers of apparatus who could use it. It would set a value on the goods that were supplied by members of the Society, and be a definite guarantee of quality to the purchasers. The Manchester agreement arrived at regarding rates of wages between the contractors and the gas companies was a very excellent piece of business. It was a matter of regret that some understanding could not be come to with those engaged in the engineering trade. Personally, he believed that if some addition could be made to their wages at the present time, with a *quid pro quo* in the shape of some alteration of hours of labour, &c., a better feeling would exist and more work would be obtained from their employees than was now the case. Negotiations were proceeding; but they seemed very slow. It was more work that was required for increased production. A friend of his had recently returned from Germany, where he visited a very large works of gas plant makers; and there he found the men were working about 60 hours a week, for the equivalent of some 31s. in the case of a skilled mechanic. It was almost hopeless for this country to try to compete in the open markets of the world against conditions such as these. The attention of members might be directed to the note in the report regarding the register of names of gas apparatus. It was a suggestion made recently, and it appeared to be a good one, that any makers who had registered names of apparatus should have them entered in the book of the Society kept for the purpose, so that they might be sure that there was no overlapping, and that names were not duplicated. As to the quarterly "Bulletin," perhaps members would say what they thought of the change-over to the issue of two half-yearly "Bulletins," and a monthly *résumé* of the work of the Council, so as to keep members a little more up to date. In the last monthly notice sent out, members were asked to let the Secretary have some information which was desired by the National Gas Council with regard to the amount of capital and the number of hands employed in their various enterprises. Only approximate figures were required; and no doubt members would send these along as soon as possible.

The membership of the Society was well maintained, and at the moment he believed numbered about 125. Their best thanks were recorded in the report to the President, Mr. Milne Watson, for his year of office. With his charm of manner and the breadth of vision displayed by Mr. Milne Watson all through his period of office, the year seemed to have passed all too quickly. Sir Alfred Mond possessed all the qualities necessary to make an admirable successor in the Presidency.

Mr. Albert W. Glover formally seconded the adoption of the report, which was unanimously agreed to.

The accounts for the year 1924 were also adopted, on the proposition of Mr. Thomas A. Braddock, seconded by Mr. J. Winson Scott.

Council Representatives of Sections.

The President announced that the following gentlemen had been elected to serve on the Council as representatives of the Sections:

Mr. J. W. Broadhead, M.I.Mech.E.,	to represent	Section I.
Major Richard Miles, B.Sc.	,,	II.
Mr. Albert E. Guest	,,	III.
Mr. R. J. Milbourne, J.P., F.C.S., A.M.Inst.C.,E.	,,	IV.
Lt.Col. W. R. Glover, C.M.G., D.S.O.	,,	V.
Mr. Cyril G. Davis, M.I.Mech.E.	,,	VI.
Mr. Philip H. Sugg	,,	VII.
Mr. Thomas F. C. Potterton	,,	VIII.
Mr. John Orme	,,	IX.
Mr. Frank West	,,	X.
Mr. H. J. Donkin, M.I.Mech. E.	,,	XI.
Mr. Joseph Taylor	,,	XII.
Dr. E. W. Smith, D.Sc., F.I.C.	,,	XIII.

New Chairman and Vice-Chairman of Council.

Mr. Samuel Cutler proposed that Mr. B. B. Waller be elected Chairman of the Council of the Society for the ensuing year. The name of Mr. Waller's firm, on the constructional side of the gas industry, was known everywhere; while Mr. Waller himself had served for about ten years on the Council, and in a quiet and unobtrusive manner had accomplished a great deal of useful work. He would therefore bring to the Chair a very ripe experience.

Mr. Harry J. Donkin seconded the proposal, which was heartily agreed to.

Mr. Waller briefly acknowledged his election, and moved that Mr. Frederick J. Gould be elected Vice-Chairman of the Council. Mr. Gould, he said, had also served many years on the Council, and in due course would make an excellent Chairman. He had done a great deal of work, particularly in connection with the Lighting Section.

Mr. Frederick C. Tilley seconded the motion, which was unanimously carried, and acknowledged by Mr. Gould.

Other Officers.

Mr. Charles Clare was re-elected Hon. Treasurer, on the proposal of Mr. G. H. Pearson Perry, seconded by Mr. Waller.

The appointment of Mr. E. J. Davison as Hon. Secretary was eed to on the motion of Mr. Albert Cliff, seconded by Mr. J. Milbourne.

Mr. J. W. Broadhead proposed the appointment of Mr. Wilfrid Drake as an elective member of the Council. They e all sorry Mr. Drake was unable to be with them. He had n a very efficient Chairman, and it was their wish to retain services on the Council.

Mr. C. A. Goodall seconded the motion, which was passed.

Moved by Mr. Clare, and seconded by Mr. H. M. Thornton, ssrs. Albert Cliff, F. C. Tilley, C. A. Goodall, and R. B. dgson were appointed elective members of the Council.

The re-election of Messrs. Cash, Stone, & Co. as Auditors to Society was agreed to on the motion of Mr. R. B. Hodgson, onded by Mr. Gould.

The Council were thanked for their services, on the proposi- n of Mr. Charles S. Bennett, seconded by Mr. Ernest ST; and a similar compliment was paid to the Hon. easurer, the Hon. Secretary, and the Secretary, on the motion the President, seconded by Mr. Thornton.

Mr. Milne Watson then proceeded to deliver the following sidential Address.

AS AND ELECTRICITY IN RELATION TO UNEMPLOYMENT AND INDUSTRIAL DEPRESSION.

I feel I need offer no excuse for taking as my subject the estion of gas and electricity in respect of the services which y are both capable of rendering to the country, as there is obably no subject which is being more discussed at the pre- t time than electricity; and we who are engaged in the gas ustry are anxious that the merits of our industry, particu- y at such a time, should not be overlooked.

Public attention has been drawn in recent years to electricity her than to gas, and great prominence is given, in the Press d elsewhere, to schemes for its development. For example, new electrical super-generating station at Barking, which d a ceremonial opening by H.M. the King yesterday, is very ich in the public mind at present. To preserve a correct se of proportion, however, it should be realized that, to sup- to the community the heat energy delivered in gas alone by near neighbour the Beckton Gas-Works, the Barking super- tion would require to have ten times its present maximum pacity. In fact, it may be said that the present capacity of s super-station is no more than the extension required nually by the largest London gas undertaking to meet the rmal increase in business. Perhaps the reason why public ention is focussed upon electricity is that its development in tain other countries has been spectacular, that the uses to ich it can be put are so varied, and that there is an element mystery and romance about it.

It is not unnatural in these circumstances that electricity has racted the attention of politicians to the extent of almost be- ning a battle-cry. The Labour Party have taken it up as a omising field in which to try experiments in nationalization, d as a help towards the solution of unemployment problems; Liberal Party have taken it up in an attempt to revive their litical fortunes, and incidentally deal with the problems of al utilization and unemployment; and, finally, the Conserva- e Party have undertaken an investigation into the whole bject.

Prevalent Ideas—and Pious Hopes.

Apart from the political aspect of the question, the prevalent ea among Members of Parliament seems to be that it would lp to solve the unemployment question in two ways: (1) By ploying a large number of men in the production of electrical nt and apparatus, in the laying of main cables, and in the ring of houses; and (2) that increased facilities for the supply electricity, piously hoped-for at cheaper rates, would enable dustry to manufacture at lower costs, and thus help to recap- re the lost markets of the world.

Labour's Proposals.

In July of last year, when the Labour Government were in ice, Mr. Snowden, Chancellor of the Exchequer, indicated at it was the policy of his Government to grant subsidies out the National Exchequer for the development of electricity in is country. He suggested that conferences should take place tween the Associations connected with electricity supply and e Electricity Commissioners, in order that agreement might reached as to the schemes of development which would rank r subsidies—in particular:

(*a*) The establishment of uniform frequency—a figure of £10,000,000, spread over three years, was mentioned in this connection.

(*b*) Government assistance for main transmission lines—"a system of grants to those authorities undertaking approved works individually or jointly, sufficient in amount to make-up the net revenue (after allowing for depreciation or sinking fund) attributable to the particular work, at a rate of interest to be fixed by the Treasury on the expenditure incurred until such time as the net revenue is sufficient to meet the charges, but not more than ten years." This proposal appears to mean that the Government would make good the deficit so long as the works remained unremunerative—with a time-limit of ten years.

(*c*) The development of electricity in rural areas. The then Government suggested that the amenities of country life could be improved. Electricity would serve for the lighting of cottages, and for electrical domestic apparatus. It was even suggested that houses might be wired on something like the hire-purchase system.

The meetings took place, and suggestions were made that the Electricity Commissioners should entertain proposals from the electrical undertakers for trunk mains and general extension to rural districts, &c., the Government to guarantee interest on capital invested for (say) ten years, or until the scheme was remunerative. Suggestions were also made that subsidies should be given for the erection of main transmission lines, overhead distribution lines to small townships, wiring and equipment of premises, and trunk mains for bulk supplies of electricity to existing distributors.

Present Proposals.

At the present time it is announced that the Transport Ministry are working out a scheme, based upon the recent report of Lord Weir's Committee which has been exploring the subject. The matter is to be debated, I believe, to-morrow, and it is understood that the Government intend shortly to introduce a Bill. As a result of all this, it is evident that there is a danger of vast sums of public money being expended in developing and bolstering-up the electricity supply industry in the near future.

An Unwarranted Excuse.

It is given as an excuse that this is necessary because the electricity industry has been hampered in the past by statutory enactments, and it cannot be expected to modernize itself at its own expense. I suggest that these handicaps have been no more than in the case of the gas industry; that the real reason is that individual undertakings have developed on lines which are not uniform; and that this is, in the opinion of certain electrical experts, a serious handicap to co-operation between adjoining undertakings. The money, if granted, would be used to defray the cost of the changes-over to standard plant, and to extend distribution to fields hitherto considered uneconomical. It is not to be wondered at, in these circumstances, that considerable surprise, indignation, and anxiety are felt in the gas industry, which is in many large fields the direct rival of electricity.

In This and Other Countries.

Many comments have been made that the electricity supply in this country lags far behind that of other countries, as regards quantity used, efficiency of production, and price charged. Dealing now with the production of electric current per head of population in various countries, as quoted during the World Power Conference at Wembley last year—viz.:

	Units per Head.		Units per Head.
Switzerland	700	Sweden	364
Canada	612	France	147
Norway	493	Germany	141
United States	472	United Kingdom	139

it will be noticed that the highest figures are attained in those countries in which not only is water power available, but where, in comparison with this country, coal is very expensive. With France and Germany we compare not unfavourably.

It is from the coal in this country that we draw all our supplies of power, whether they are ultimately utilized as steam, gas, or electricity. There is no supply of "white coal" (as water power is commonly called), such as there is in Canada, the United States, Norway, Switzerland, and many other countries. It is possible that in course of time the water resources of Scotland and Wales may be utilized; but these are far removed from the great industrial centres of England, and even if, eventually, the tides are harnessed for the purpose, these sources are not practicable at present. Moreover, it should be remembered that the capital cost of such water-driven installations is much higher than for steam-driven generating stations.

Doubtful Economy of Long-Distance Transmission.

Seeing that water power is not available in this country for large-scale generation of electricity, proposals have been made for the centralization of the production of electricity in the shape of super-stations; but here, again, the trouble is that, if the cost of long-distance transmission is added to the heavy capital charge, it is found that such savings as are effected in the fuel costs are counterbalanced. It should be remembered that in this country it is usually cheaper to convey coal over long distances than to convey electric current.

To quote from the recent address of the President of the Institution of Electrical Engineers: "It is obvious that in a country where coal is dear the advantages of centralization of power production are greater than in a country such as our own where coal has been cheap. As a consequence, the development of electricity supply in countries where water power is available and where coal is dear has been much more rapid than in this country, not, it will be noted, necessarily due to a spirit of greater enterprise, but primarily because it was the best or only economic solution of the power problem."

What is essential to a country is a cheap supply of power, light, and heat. It is assumed by far too many people in this country that the prosperity of the country should be judged by

the quantity of electricity consumed. I, on the other hand, consider that, in judging the country's resources, all circumstances must be taken into consideration, because upon the nature of such resources will depend the lines upon which development can take place with the greatest advantage. This is not generally realized.

The Service Rendered by Gas.

In this connection, I would now draw attention to the magnitude of the service rendered by gas to the community in this country. In Great Britain the consumption amounts to 275,000 million c.ft. annually, which equals approximately 1320 million therms; and taking the population at an estimate of 47,350,000, this works out at 28 therms per head of the population. The amount of electric current required to do the work actually performed by this quantity of gas in its various uses by the public is calculated at 487 kw.h.—that is, units—per head of the population. Therefore, the service given by gas *per capita* in this country exceeds that given by electricity in the United States of America. If one adds the heat energy supplied by gas undertakings in the form of coke, the figure per head of population is more than double that quoted. It is worthy of note that, although gas manufacture has not developed in the United States of America in the same proportion to the population as in this country, partly owing to the fact that supplies of natural gas have become available, it is making great progress, having increased by no less than 33 p.ct. during the last six years, in spite of the intense electrical development of that country. I am not claiming, of course, that gas can be used with advantage for every purpose. There are instances in which electricity is specially adapted—such as railway traction, power distribution to a large number of units (we use electricity in gas-works); and for lighting it has its special uses. On the other hand, there are purposes for which gas is peculiarly suited; and in these fields, in which gas is mainly used, there is no advantage in changing-over to electricity. In fact, positive disadvantages to the nation would accrue if such a course were adopted, as I shall show. For example, heating, industrial or domestic, and cooking are fields in which gas far out-rivals electricity.

The Bye-Products which are Lost in Generating Electricity.

Moreover, in dealing with this question, it must not be overlooked that electricity produces no bye-products. Gas manufacture produces per annum (1924)

0,000,000 tons of smokeless fuel—viz., coke.

172,000,000 gallons of tar, which in distillation provide:

Prepared road tar.	Beta naphthol.
Carbolic acid.	Salicylic acid.
Creosote.	Anthracene.
Naphthalene.	Pitch, &c.

167,000 tons of sulphate of ammonia (one of the chief agricultural fertilizers), cyanide, and other bye-products.

Thus the gas-works recover all the valuable bye-products from the coal, including the raw materials for dyes, drugs, disinfectants, benzole (the only home-produced motor fuel), fertilizers, &c., which are destroyed when coal is burned in its crude state, as in electrical generating stations.

Coal Conservation *v.* Coal Wasting.

This brings me to the all-important question of the conservation of coal. The comparative thermal efficiencies of gas and electricity works are such that, of every 100 heat units in the coal used, the most efficient electric generating station utilizes only 20 p.ct.—a loss of 80 p.ct.—whereas in efficient gas manufacture the loss is only 15 p.ct. That is, gas-works can supply to the community as gas, coke, and chemical products, 85 p.ct. of the total heat value of the coal. It is clear, therefore, that in utilizing to the best advantage the nation's coal supplies, gas is playing a far more important part than electricity, and gives to this country distinct advantages over a country which depends entirely upon electrical power and heat.

State Subsidies Wrong in Principle.

In my view, the granting of subsidies to industry—especially to industries which are sheltered—is wrong in principle. The gas industry was built-up in face of tremendous opposition and prejudice, and in face of many restrictions of a statutory character, many of which exist at the present moment. Yet in Great Britain the gas industry is certainly as efficient as that of any country in the world. On the manufacturing side, large sums of money have been spent in modernizing plant to keep pace with the better practice brought about by experience and greater knowledge, and on large mains in lieu of small ones to deal with increased loads and with the increased volume that altered conditions in manufacture and utilization have necessitated. All this has been paid for by the gas industry itself. What is the matter with electricity? It is true that per head of the population there is not so much electricity used; but that is because in this country industrial development commenced earlier, and has been along other lines, and to a great extent electricity is in competition with other forms of power already in being, instead of having, as in some countries, a virgin field for development.

The question at once arises, Why should not the electrical industry itself pay for any improvements in the method of the generation and distribution of current? The electricity industry cannot possibly be termed a "depressed" industry, as we shall clearly prove. We are also entitled to ask, from the country's point of view, What advantages, if any, are there in the alleged "improvements"? For instance, is a policy of erecting large super-stations, linked-up all over the country, a sound policy for Great Britain? Will super-stations provide electricity much cheaper than smaller sources of electricity?

Super-Stations Not Necessarily the Most Efficient.

In the recent report issued by the Electricity Commissioner it is recorded that the highest thermal efficiency was obtained by a small internal combustion engine station. For steam operated plants the best efficiencies are by no means confined to the super-station; but, in any case, where improvements have been effected in the over-all thermal efficiency, they are so small as to have only a slight effect upon the cost to the ordinary consumer. This is because the cost of distributing mains and apparatus is high, and in the case of intermittent use, as for lighting, distribution may be said to add 300 p.ct. to the cost of generating.

Concentrating the generation of current at super-stations entails long and expensive high-tension lines and losses of power. This is the reason why it is more economical to bring coal from (say) South Wales to London for the generation of electricity than it would be to establish generating stations at the coal fields and transmit the current. The cost of generation at super-stations, *plus* transmission to switchboards of existing distributing centres by the proposed national system, has been placed by one of its advocates at 0·6d. per unit. Many of the great centres of industry have already electric supplies generated at this price, and have, therefore, little advantage to look for. It would appear that it is only districts uneconomically situated which would benefit, at the expense of the State, by what is proposed.

Possibly in future developments centralized production will offer advantages in the better utilization of capital, more skilful operation, and pooling of the load; but, even if it were so, why should the State provide money for this purpose? There are many other industries which have been hampered in the past by legislation and other obstacles, and which have become old-fashioned, and are not able to compete favourably with their trade rivals. Is it sufficient to prove that modernization is needed for grants to be received from the State? If Parliament does insist on subsidies being given, they should be given only by way of loans; and, in fairness to other rival industries, loans should be given to them on similar terms. ["Hear, hear." But as this means that the requirements of every industry should be on the same basis, it would be much better if there were no subsidies at all.

Electricity in No Need of Subsidies.

I now ask for proofs that the electricity industry is financially embarrassed. To judge by the available figures, there are no signs whatever of this. "Garcke's Manual" gives the average dividends on ordinary capital of 176 electric supply companies in 1914-15 as 4·04 p.ct., and of 194 companies in 1923-24 as 7·1 p.ct.; and, in addition, there is evidence of large increases in reserve funds. Such up-to-date figures as are available give even greater evidence of prosperity. Take, for example, a number of the London Companies:

—	Amount to Reserve.		Dividend	
	Pre-War Year	Post-War Year.	Pre-War.	Post-War.
	£	£	P.Ct.	P.Ct.
Charing Cross Company—				
West-End undertaking . .	22,000	46,000	5	15
City undertaking	18,000	93,000	*Nil*	10
Chelsea	14,000	32,000	5	12
Kensington	8,800	33,000	9	15
London Electric	33,000	63,000	4	10
Metropolitan.	23,000	206,000	3½	11
City of London	51,000	184,000	9	15
South London	7,500	67,000	5	15
South Metropolitan . . .	15,000	119,000	*Nil*	15

These facts indicate that the electrical undertakings must be in a position to attract all the capital required for legitimate and useful expansion of business. ["Hear, hear."] We do not but suspect that the real reason for State aid being sought for the electrical industry is that there is a body of persons in this country who wish to see an expansion of electricity apart from any economic consideration, and are anxious, therefore, that for this purpose the taxpayer should bear the burden. There are no signs of lack of funds for remunerative schemes, or that the industry is unable to shoulder its own burdens. If the electrical industry is to be bolstered-up and given unfair advantages, it is a very serious matter for the gas industry.

The National Importance of the Gas Industry—in War and Peace.

The country cannot afford to neglect the gas industry. Gas is the best and most natural way to use coal in this country for a great variety of purposes, and in it and its bye-products lies the

tion of the smoke problem. It will be remembered that ng the late war it would have been impossible to provide high explosives necessary to carry on without the aid of the industry; and in times of peace it is no less essential to the luct of other industries.

the gas industry were to be prejudiced by the unfair com-ion of a subsidized rival, and people were to be induced to electricity by the provision of a cheap supply of current at cost of the public generally, and incidentally at the cost of gas industry as members of the public, a great injustice ld be done to our industry. [" Hear, hear."] Municipali- alone have expended capital to the extent of £58,000,000 in gas undertakings, which are perhaps the most successful nples of municipal trading. If they are to be exposed to competition of a State-aided rival industry, whatever age is done to their interests will fall eventually upon the ayers.

here are 312 municipal electric supply undertakings, with orized loans totalling £108,331,266, and 150 municipal elec-traction undertakings, with authorized loans amounting to ,258,120. Speaking of municipal undertakings, in cases re the generating costs of these undertakings exceed those of current supplied by a super-station, they would, under the onal scheme, so far as we know, be compelled to shut-down generating plant. The interest on the capital of the plant thrown idle would have to be reckoned against the reduc-in the cost of current. In the case of companies similarly cted, it is apparently the intention to compensate from State ls.

Gas Employs Far More Labour than Electricity.

we were looking at this question merely from the point of of unemployment, it is interesting to note that the gas stry employs more than five men for every one that the tricity industry employs for the same output of heat energy. refore, the bolstering-up of electricity, should it bring about eduction in the amount of gas consumed, would put the ntry in no better position as regards employment in these industries taken together.

he same remark applies to the associated industries which Society of British Gas Industries comprises. They employ our on a very extensive scale in the manufacture of plant, chinery, apparatus, and materials in connection with the nufacture and utilization of gas and its bye-products. The lity of their work has been kept up-to-date and on a high le by standardization of essentials and by healthy competi-. Their work is of national importance in that it is helping to in the greatest efficiency in the development and application of stored-up energy in coal; also, in that many of these British s have been able to compete successfully in the markets of world. This progress has been made without financial aid n the State, direct or indirect; and now, if State subsidies to give an unnatural fillip to electricity, any increased em-ment there may be in the manufacture of electrical ap-atus is bound to be negatived by a corresponding reduction our own associated industries. The Society of British Gas ustries, like the parent industry, asks for nothing more than competition and natural development on economic lines. Hear, hear."]

Cheap Electricity Fails to Cure Tyneside Depression and Unemployment.

he belief that the development and increased supplies of tricity will remove unemployment in other industries in this ntry is entirely fallacious. There is no greater depression he present time than on the North-East Coast, where there the largest super-stations in this country, belonging to an tricity undertaking probably as up-to-date and efficient as in the world, supplying cheap electricity over 1400 square es of industrial area. Although the mining, steel, shipbuild- and other industries have availed themselves of this cheap tric supply, it cannot lift them out of the abyss of depression which they find themselves; it represents too small a pro-tion of their total working costs. In shipbuilding, marine ineering, locomotive building, and iron foundries, the cost of tricity represents under 1½ p.ct. of the total working costs; hat any reduced price of current cannot materially affect the sent abnormal conditions. It is stated that recently, in con-tion with a contract for eight new ships for the Blue Star e, where the total expenditure was to be in the neighbour-d of £2,700,000, foreign tenders were no less than £300,000 ow those of British firms.

Hopes Doomed to Disappointment.

The Prime Minister has said that " we consume less units of trical power than countries far inferior to our own in indus-l production," and that " there is no doubt that to-day we paying infinitely too much for our light and for our power." ould point out, however, that in the case to which I have rred a cheap supply is available; but it is obvious that this is sufficient, and that even if electrical power were supplied s of cost it would not make good more than one-eighth of the crepancy in these shipbuilding tenders. The causes of unem-yment go a great deal deeper than the cost of electricity; and ose in responsible positions should hesitate before they put ir faith in the proposition that electrical power, however cheap, will re-start trade and solve the unemployment problem in this country. [" Hear, hear."]

These remarks are made in no spirit of the dog in the manger. Electricity has its uses, as well as gas, and we have no ill-wish towards our rivals. We maintain, however, that they should not be unduly favoured by the State as against gas.

The latent energy stored in coal is the greatest natural asset in this country, and upon it depends our ability to hold our position in the civilized world. Already the exhaustion of the more cheaply-worked seams is in sight, and the need for conservation is very urgent.

Electricity Wasteful of Coal.

The approximate consumption of coal for domestic purposes in this country is in the neighbourhood of 35 million tons per annum. Prof. Cobb has shown that, assuming only one-quarter of the heat in the coal thus burned is usefully employed, to supply this heat by electricity instead would require, on the most optimistic assumptions, approximately 55 million tons. Now the same amount of heat supplied as smokeless fuels—gas and coke—by gas-works would require under 30 million tons. Thus the adoption of electricity, if it could be universally adopted, would mean the additional expenditure of 20 million tons, as compared with a saving of 5 million tons by the gas-works solution—a difference in favour of gas manufacture of 25 million tons of coal, *plus* the valuable tar and ammonia products required for other industries, which would be as much a loss in the process of electrical generation as they are in the present domestic practice of sending them up the chimney.

It would be nothing short of scandalous to allow State funds to be given to foster the use of a far less efficient medium, and so deliberately encourage waste of the national resources. [Applause.]

Sir Arthur Duckham, in proposing a vote of thanks to Mr. Milne Watson for his address, and for his services to the Society, said the President was worthy of all the praise that one could give to him; but they in the gas industry knew that in Mr. Milne Watson they had the leader, the head, of their industry. They knew the burden upon his shoulders, and all that he had done for the unification of the industry; and they knew that in a time of crisis like the present, in industry in general, and in the fuel industries in particular, Mr. Milne Watson would follow-up the work that he had done. He felt certain that the address just delivered was the most vital Presidential Address to which they had ever listened; and it was an address which was greatly needed to-day. Friends of his had come to him and asked whether they should sell gas shares, as gas was finished, and there was nothing left but electricity. In fact, an entirely false position had been built up in this country by the present cry of electricity for everything. As a matter of fact, the country did not want electricity; it did not really care about electricity. What this country wanted was a cheap and efficient supply of energy, in whatever form it might be, suitable for its requirements; and the great danger of the present situation was that inquiries, such as Lord Weir's Committee, had been only on the basis of electricity, and had not been on the basis of the general fuel position of the country—which should be the basis of any inquiry. It seemed to him a terrible thing to crystallize generation of energy on an 80 p.ct. inefficiency, or 20 p.ct. efficiency, such as was entailed by the proposed super-power stations. Surely this was not a time for great expenditure, but to make the best use of what one had got. There was much in this country that should help to cheapen power. As to unemployment he was entirely at one with the President. A case had come under his notice of two similar jobs in England and America. The wages in America were just four times the English rates; but the cost of the job was actually the same—showing that the output of the American worker was four times the output of the English worker. This extra output was not due to an electric motor being attached to each worker. Naturally, one wondered what the Government were going to do about electricity. Inquiries had been held; but all one knew as to the results was that the electrical engineer walked about with his tail up, and when asked what was going to be done replied: "Wait and see, but it is something pretty good." One feared the Government had made up their minds before the question had been put forward for discussion, and that thus the thing might be rushed through without properly weighing matters up. This must be bad for the country, the whole situation having only been considered from the one point of view. They must all feel frightened that some very grave error might occur, unless there was proper time for consideration and consultation upon these matters. Finally, as far as one could see, an entirely bureaucratic scheme was foreshadowed. They had seen a little of the present Electricity Commissioners. A works wanting to put in a gas engine and dynamo plant was referred to the Electricity Commissioners—although it was a gas-works—and an attempt was made to force the Company to take their power from the electricity station, though the price would have been far higher than that at which they could generate the current on their own works. It was foreshadowed that the Commissioners in London would have absolute control of the generation of electricity throughout the country. It would be a magnificent thing for the gas industry if they did. Nothing could kill an industry more surely than such control from one central authority. Any attempt to

rush a scheme through without considering the matter from all points of view must be disastrous. Mr. Milne Watson had a very hard year in front of him in every direction; and he wished to tell him on behalf of the members that he had the hearty support of one and all of them. ["Hear, hear."]

Mr. Waller said he was very pleased to have the opportunity of seconding the vote of thanks to the President for his very able address on the subject of electricity, and for his services to the Society during his year of office. On every occasion when it was necessary to consult him, he gave them the impression that the work of the Society was the only subject of any importance to him at the moment, though they knew how overburdened he had in reality been during the last year with other urgent affairs.

The vote having been carried with acclamation,

The President remarked that it had been a great pleasure to him to be associated with this very distinguished body of industrialists. He was sure he had learned as much from them as they could possibly have learned from him; and his year of office had been a singularly pleasant one. In the gas industry, whether on one side or the other, their great object was to pull together for the general good. With regard to the subject of the address, this was certainly going to be a pressing question for them during the next twelve months. It was not going to be disposed of by one speech from the Presidential Chair of the Society. This electricity "stunt"—if he might so term it—had got a great hold on people, who forgot altogether that gas had already done more in the direction of smoke abatement than electricity had ever done or was ever likely to do. The chief offender in this respect was the domestic chimney; and it was the gas undertakings that could, and did, deal with them. The gas industry was going to do away with the smoky atmosphere of the towns. Providence had put this work into their hands to do. Members should never cease putting the whole matter before people in influential quarters, and trying to get them to see the error of their ways. In the first place, to do as was proposed would not solve the problem of unemployment; and, secondly, it would be an act of injustice. There were able men in the electrical industry who were quite capable of raising any money that was really necessary. It was the business of the gas industry to expose the folly of the proposals now being made.

The New President.

The President (continuing) said it was now his very great pleasure to present to them the new President, Sir Alfred Mond. [Applause.] It was hardly necessary for him to introduce that gentleman to them; his name was a household word all over Great Britain, and among gas people it was well known. No one had rendered greater service to this country in commercial matters than Sir Alfred Mond, and they looked to him as one who understood some of their problems. If the Government would only consult Sir Alfred, he himself had a scheme for dealing with unemployment which was probably a great deal better than the electricity one suggested by the Government. They were all honoured that such a distinguished public man had found time, among his numerous other duties, to accept the Presidency of their Society.

The Right Hon. Sir Alfred Mond, Bart., M.P., said he regarded it as a very great honour indeed that they should have so kindly elected him to this responsible position. He felt, however, a much greater sense of trepidation than would otherwise have been the case, because he was succeeding in office such an expert in all gas questions as Mr. Milne Watson, to whose masterly address they had just listened. This address showed that Mr. Milne Watson combined, with great technical and commercial ability, also statesmanlike qualities. As for himself, his connection had been more with the furnishing of cheap power by means of producer plants and gas engines, and with a firm well known among gas engineers—Messrs. Ashmore, Benson, Pease, & Co., of Stockton-on-Tees—in supplying plant for gas-works. He did not wish to enter into the very large subject which the address had opened up. He would say, however, that politicians were well known to be ignorant men on technical matters. [Laughter.] He heard people talking gaily about super-power stations who did not know the difference between a volt and an ampère, and who had never seen a dynamo. "Super" meant nothing at all to any technical person. The question of whether large apparatus was preferable was one of pounds, shillings, and pence; and there was a great deal to be said on the side of limitation of units in all forms of plant. For instance, there was the question of spare plant and parts. One could easily develop to a size where the capital outlay in this respect became so high that, when they took this and depreciation into account, the financial results would be worse, though the technical results might be a little better. Politicians, as he had said, were not, on the whole, very well acquainted with technical subjects. Electricity had come much to the fore in countries where water power was cheap and coal dear. But the assumption that they must necessarily follow the same course in this country had always seemed to him to be quite unwarranted, unless they could demonstrate that other conditions intervened. He was rather surprised that it had been so long before they had a paper of this character, and that so little publicity had been given to gas; and he would very much recommend that a copy of this address should be sent by the Society to the Prime Minister, to Mr. Lloyd George, and to Mr. Snowden, as well as to Members of Parliament generally ["Hear, hear"], so that they at any rate would have the aspect of the case presented to them. Gas had been established so long that people had lost interest in it; electricity was a newer baby, and therefore likely to attract more attention. The position of the gas industry, its importance to the country, its functions in relation to domestic heating and lighting, and its industrial uses, should be thoroughly recognized by those who were responsible for dealing with a complex problem presenting so many aspects. If he could render any assistance to the gas industry, he would be only too pleased to do so.

Annual Dinner.

Later the members and a large number of guests met again in the Hotel Cecil, where just over one hundred sat down to the annual dinner, and spent a thoroughly enjoyable evening. Perfect arrangements, backed up by topical speeches and some charming musical items, made the occasion a memorable one alike to members and guests. The President (Mr. D. Milne Watson, D.L., M.A., LL.B.) was in the chair; and on his left hand there sat the Right Hon. Sir Alfred Mond, Bart., M.P. (the President-Elect), Sir Arthur Duckham, K.C.B., M.Inst.C.E., Mr. William Cash, F.C.A., Mr. Samuel Cutler, A.M.Inst.C.E., M.I.Mech.E., Lt.-Col. C. F. T. Blyth, C.M.G., LL.D., Mr. Frederick C. Tilley, M.I.Mech.E., Mr. Thomas Hardie, M.Inst.C.E., Mr. J. W. Broadhead, M.I.Mech.E., Mr. Philip G. G. Moon, Mr. J. Conway Davies, and Mr. Arthur L. Griffith. To the right hand of the President were the Right. Hon. Sir Hamar Greenwood, Bart., K.C., M.P., Mr. B. Waller, Assoc.M.Inst.C.E., Mr. J. Ferguson Bell, M.Inst.C.E. (President of the Institution of Gas Engineers), Mr. Frank H. Jones, M.Inst.C.E., Mr. Charles Clare, Mr. R. W. Foot, Mr. Douglas H. Helps, Assoc.M.Inst.C.E., Mr. F. W. Goodenough, Mr. Henry D. Madden, M.Inst.C.E., Mr. Cyril G. Davis, M.Inst.Mech.E., and Mr. John Terrace, M.Inst.C.E. The programme of music was arranged by Mrs. Millicent Russell. The toast of "The King" having been honoured,

The Society.

The Right Hon. Sir Hamar Greenwood, Bart., K.C., M.P. said fate had decreed that he should be their guest that night, and propose the toast of "The Society of British Gas Industries." He appreciated the compliment of being invited to do so. At the same time, he must frankly say he could not possibly have a tithe of the knowledge of these great industries which was possessed by the youngest of the members. But he could say something in a general way. He wished to say something of the President, who would respond to the toast, and who spoke with the prestige of a knowledge of the subject which was possibly unrivalled; and he wanted also to say something—and here he could speak with most intimate knowledge—of the President-Elect. Sir Alfred Mond and he had been a great many years in Parliament together. They had sat in the Cabinet which he (the speaker) still thought was the best Cabinet that had ever presided over the destinies of this country; and he was sure that his friend agreed with him. He felt bound to say of him that, if they were to choose half-a-dozen of the leading business men of the great parent country of a great Empire, Sir Alfred Mond would be one of them; and he thought he could say that Sir Alfred was one of the outstanding and illuminating enrichments of the commercial and political life of the country. He (the speaker) was not agreeing with him every time now; and it did not necessarily follow that he (Sir Hamar) was wrong. But he was bound to confess this—that, if he were right, Sir Alfred could put his case with facility, eloquence, and conviction that he regretted he could no himself equal. However this might be, he congratulated the Society upon having as their President-Elect a distinguished statesman and a leader of industry, not only in this country, but in the Empire, who could stand up in the House of Commons and command the attention of that difficult and hypercritical, and not always—should he say—knowledgeable, assembly, on industrial matters. As to their President, it was to be regretted in some ways that he had left the noble profession of the law to become Governor of the Gas Light and Coke Company; and that, instead of hanging criminals who should be hanged, he spent his time in declaring fine dividends and increasing reserves. [Laughter.] He did not know whether he was always satisfied to be the distinguished Governor, and the successor of a great many distinguished Governors, of the Gas Light and Coke Company, or whether he regretted sometimes that he was not able to put on a black cap and do something for somebody. Now he had always thought himself that the history of the gas industry represented one of the greatest tests—and successful tests—of British character. He had taken occasion to read it up, although in days gone-by he knew well the late Sir Corbet Woodall, who was one of the most enthusiastic members of that Society, and one of the leading men in the gas industry of the country. He had always thought that from the earliest days of this industry, which had commenced over a hundred years ago, it had had to wage a constant fight to overcome ignorance and break-down tradition; and in the more recent years they had had to fight a competition which was already severe, and might grow still severer as time went on. They found that the celebrated Duke of Wellington to the day of his death believed in candles; and as long as he was in authority, he insisted upon every soldier continuing to carry candles in his knapsack, as he had done in the days of Marlborough and at Waterloo. Prejudices died hard in those days, and even now; but this could be said—that here in this little island the gas industry commenced and through English engineers and English capital it spread throughout the whole of Europe, and to other parts. There was a time, he supposed, when hardly a town of importance in Europe did not have its gas plant put down by the capital of English investors. ["Hear

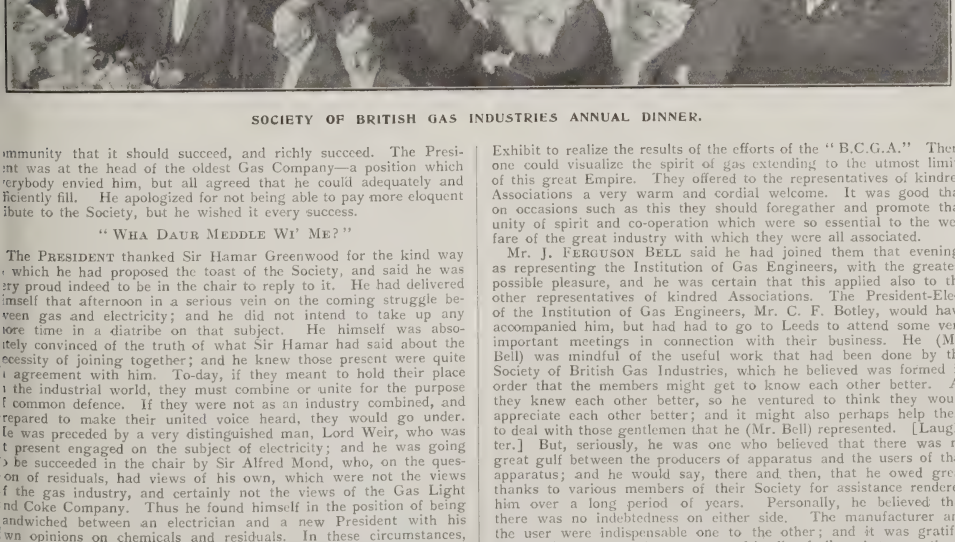
r."] This was a great compliment to the originality, and more ticularly to the tenacity, of the people of our race.

UNITY IS STRENGTH.

y had now organized themselves into a Society, and he would to say just a word or two on this. He did not believe it was sible in this modern world—with industrial competition growing r more fierce—for any industry, or group of industries, like theirs, nany different kinds, to exist unless they united, and had a com- n purse, with a common object, to fight common competitors out- e their realm. He thought, therefore, they were wise to unite ether as they had done; and if he had his way, he would have industries in this country united in a similar manner. He had ently returned from another great industrial country, Germany. would be an impertinence for him to quote his opinion against se of the great bankers and the great industrialists; but he was ng to do it. He believed that Germany was working to-day h a zeal, with an energy, with a cohesion, and with an intelligence t in five years—no longer—would again place her at the very top the commercial interests of Europe; and not only this, but would ain make her the predominant military power. Those who sat e in wonderful, splendid, lovely England seemed to be more on defensive than were the people in that great competitive Ger- ny; and in this rough world of economics, it was not because a ntry was beautiful or the people lovable that they would neces- ily succeed. They were faced at this moment with competition m Germany which he did not believe one man or woman in a ndred realized. The members of that Society at least were wise, d were doing what they could in every way to meet what he thought uld be the severest competition that would come from Germany, d which had already started to come. He would couple with toast the name of the President who was just retiring. Mr. lne Watson represented a Company who all through their long reer had stood, as he (the speaker) thought, for the best interests the community they had so faithfully served. One of the prejudices y must all try to break-down was that the success of a gas or ilar company meant that it was militating against the welfare the community. On the contrary, it was in the interests of the spirit, they could meet together, and President could succeed President, all working as they believed for the good of the nation generally. For his own part, he could assure them that he had been very proud indeed to be President of the Society. No duty had been more pleasant; and no time had passed more quickly. He had in his own work been helped very largely by their advice and by their support; and he hoped that after his retirement from the chair they would always allow him to remain with them in sentiment and in feeling.

Before sitting down, the President announced the receipt from the Lord Mayor of Manchester (Alderman Fred. J. West) of a telegram expressing regret at his inability to be present owing to a special Council meeting, and sending best wishes and greetings.

Mr. B. B. WALLER submitted the toast of "Kindred Associations;" remarking that it was very gratifying indeed to the Society to have so many representatives of other organizations with them that evening. It indicated the existence of that spirit of good fellowship which was so essential to their general welfare. It was not his intention to enlarge on the activities of these various Associations. The good work they were doing was well known to all of those present, and was very highly appreciated. He was pleased to know that they had with them, as representing the parent body, Mr. J. Ferguson Bell, the President of the Institution of Gas Engineers, and Presidents, &c., of different District Associations, representing that great body of gas engineers who were ever pressing the members of the Society for plant of increasing capacity to meet their growing needs. Then they had with them their esteemed President, as representative of the National Gas Council. One need be only a very minor member of that body—as he (Mr. Waller) himself was—to realize the extraordinary amount of useful work that was being carried out by them. Then, again, there was the child of prodigious growth, with the insatiable appetite, who was always asking for more—the British Commercial Gas Association. The "B.C.G.A." had been well represented there that evening by their old friend Mr. F. W. Goodenough, who, by the way, he was sorry to say, had been obliged by indisposition to leave them. Mr. Goodenough's name was synonymous with great achievements. One had only to go to Wembley and see that great Gas



SOCIETY OF BRITISH GAS INDUSTRIES ANNUAL DINNER.

mmunity that it should succeed, and richly succeed. The Presi- nt was at the head of the oldest Gas Company—a position which erybody envied him, but all agreed that he could adequately and ficiently fill. He apologized for not being able to pay more eloquent ibute to the Society, but he wished it every success.

"WHA DAUR MEDDLE WI' ME?"

The PRESIDENT thanked Sir Hamar Greenwood for the kind way which he had proposed the toast of the Society, and said he was ry proud indeed to be in the chair to reply to it. He had delivered imself that afternoon in a serious vein on the coming struggle be- veen gas and electricity; and he did not intend to take up any ore time in a diatribe on that subject. He himself was abso- tely convinced of the truth of what Sir Hamar had said about the ecessity of joining together; and he knew those present were quite agreement with him. To-day, if they meant to hold their place the industrial world, they must combine or unite for the purpose f common defence. If they were not as an industry combined, and repared to make their united voice heard, they would go under. le was preceded by a very distinguished man, Lord Weir, who was t present engaged on the subject of electricity; and he was going be succeeded in the chair by Sir Alfred Mond, who, on the ques- on of residuals, had views of his own, which were not the views f the gas industry, and certainly not the views of the Gas Light nd Coke Company. Thus he found himself in the position of being andwiched between an electrician and a new President with his wn opinions on chemicals and residuals. In these circumstances, e would suggest, as a suitable motto for the gas industry: "I'm ee Jockie Elliot; Wha daur meddle wi' me?" After all, there as no doubt that the fact that they in this country did not always et on very well together led partly to the strengthening of the ational character. They knew how to fight and how to be friends; nd although they had differences, they still remained friends. It as one of the characteristics of the British nation that they knew ow to fight and how to remain friends; and though they might iffer on certain questions, yet at the same time there was a friendly Exhibit to realize the results of the efforts of the "B.C.G.A." There one could visualize the spirit of gas extending to the utmost limits of this great Empire. They offered to the representatives of kindred Associations a very warm and cordial welcome. It was good that on occasions such as this they should foregather and promote that unity of spirit and co-operation which were so essential to the welfare of the great industry with which they were all associated.

Mr. J. FERGUSON BELL said he had joined them that evening, as representing the Institution of Gas Engineers, with the greatest possible pleasure, and he was certain that this applied also to the other representatives of kindred Associations. The President-Elect of the Institution of Gas Engineers, Mr. C. F. Botley, would have accompanied him, but had had to go to Leeds to attend some very important meetings in connection with their business. He (Mr. Bell) was mindful of the useful work that had been done by the Society of British Gas Industries, which he believed was formed in order that the members might get to know each other better. As they knew each other better, so he ventured to think they would appreciate each other better; and it might also perhaps help them to deal with those gentlemen that he (Mr. Bell) represented. [Laughter.] But, seriously, he was one who believed that there was no great gulf between the producers of apparatus and the users of that apparatus; and he would say, there and then, that he owed great thanks to various members of their Society for assistance rendered him over a long period of years. Personally, he believed that there was no indebtedness on either side. The manufacturer and the user were indispensable one to the other; and it was gratifying to know that there was a friendly feeling between them. He thought, speaking for himself, that the Society of British Gas Industries and the Institution of Gas Engineers might become more closely associated with advantage to both. ["Hear, hear."] An interchange of views must be always beneficial. Of course, when the makers of apparatus placed their views before gas engineers, the latter did not always agree with them. In fact, they sometimes thought the makers took a limited view of things, especially in the matter of prices. [Laughter.] But the makers might

also think that the engineers took a limited view of the position; and so it was well that they should know each other, and that they should be able to realize the difficulties each had, and their limitations. The material welfare of this country was very closely bound up with the engineering and chemical industries; and anything that could be done to promote the interests of these two great branches was to the benefit of the community at large. Therefore he was glad to be with them, to say how much gas engineers appreciated the efforts the Society were making. Unity was strength; and the members were wise to combine together to make productive efforts.

THE PROBLEM OF TO-DAY.

English manufacturers for too long a period had been dissociated; but now they had come together, and there was no reason why they should not help one another, as gas engineers did—though, of course, there was no rivalry as far as gas makers were concerned, except rivalry in giving the best service they could to the community. There was no doubt that what they were all suffering from at the present time was the acute unemployment question, which was possibly the most difficult problem they had to deal with to-day. On his way up to town that day, it had been with the greatest possible pleasure he had read a leading article in "The Times" with reference to the proposals of the President-Elect for dealing with this labour question. Sir Alfred Mond had put forward what he (Mr. Bell) ventured to think was a statesmanlike view of the situation. ["Hear, hear."] He hoped the Government would give very serious consideration to the question of subsidized wages. As "The Times" pointed out, Sir Alfred Mond had performed a valuable public service. The obvious advantages of maintenance with work, as against maintenance without work, must be recognized by all parties. It was easy to criticize; but he hoped the politicians, instead of looking for difficulties, would give the proposal a fair trial, and see what could be done. Everyone must realize that the dole was demoralizing to the manhood of the country, and was making men work-shy. The question of unemployment was one that the manufacturers had got to meet in some way; and to do so they would have to produce goods at such a price as potential buyers could pay, and as would enable them to hold their own against Continental and other competition. Sir Hamar Greenwood had pointed out that they would have to meet more severe competition in the future than in the past; and he felt quite certain that what he had said with reference to Germany was true. It must be realized that, now the war was over, this country was poorer, and the people would therefore have to work harder in the future than in the past. What was necessary was a drastic curtailment of expenditure. Certain trades and industries were being taxed, Imperially and locally, out of existence. Costs must be cut-down, so that they could hold their own with competitors. The gas industry feared no competition, so long as that competition was fair; and he did hope that those gentlemen who were prominent in Parliament would see that gas, as an industry, had a fair field—which was all they asked for. They did not want any favours.

PRESIDENT-ELECT'S INDUSTRIAL "MEDICINE."

Mr. FREDERICK C. TILLEY proposed "The New President," and said that Sir Alfred Mond did not need any introduction to them. He was so well known throughout the whole world that they did not need to be told who or what he was. They welcomed him heartily, and thanked him for becoming their President. ["Hear, hear."] During the life of the Society, they had had many illustrious men as President—great engineers, great industrialists, representatives of the law, and of medicine—and now they could congratulate themselves, when they considered the record of Sir Alfred Mond, that in him they had a President who combined the whole of these qualifications, with the exception, perhaps, of that of medicine. He did not think he had taken any part in medicine of the usual kind; but he had during the last few months endeavoured to introduce "medicine" to the industrial world, in the shape of a very daring scheme for improving the lot of everyone in the country. The proposal Sir Alfred had brought forward was one which he hoped would have very speedy attention, because something of the kind had certainly to be undertaken to bring about the necessary change in existing industrial conditions. He hoped it would be possible to give the scheme a trial; and Sir Alfred Mond was heartily to be thanked for bringing it forward at a time when it was evident that something must be done to cope with this urgent and difficult problem. He was sure they had only to look to their new President for guidance, and they would receive it, and would be proud to receive it, from one who was so eminently well qualified to give it.

The Right Hon. Sir ALFRED MOND, Bart., M.P., thanked Mr. Tilley for what he had said, and also his old friend and colleague Sir Hamar Greenwood for his kind words. He and Sir Hamar had worked together under conditions of great strain and difficulty—and when the latter occupied a position, not only of great responsibility, but of great personal risk, in being Chief Secretary of State for Ireland; a position in which he showed that determination and that great courage for which he had always been distinguished. He also wished to thank Mr. Ferguson Bell for his sympathetic allusion to the scheme which he (the speaker) had put forward after much consideration for dealing with the problem of unemployment. It would take up too much time, and it was scarcely the opportunity for him to go into the scheme in any detail; but he would just like to say that he was quite convinced the country could not afford to go on sitting still and doing nothing. ["Hear, hear."]

HELP FOR BRITISH INDUSTRY.

He, like many others, had been hoping against hope that trade would resume its normal conditions, and that no extraordinary measures would be required to get them back to the position in which unemployment would be once more reduced to manageable proportions. Anybody who looked into the matter must have realized that year after year the unemployment figures of this country remained of an alarming magnitude. Anyone engaged in industry must have felt that there was being deteriorated month by month, week by week, and day by day, the material on which they would have to rely if industry was to improve. The fundamental questions were: Could they afford to take the risk of being unorthodox, and to adopt a scheme which might or might not produce inequalities between one firm and another; or could they afford to allow things to go on as they were to-day? Could they afford to see their human material deteriorate? Could they afford to allow a whole generation of young people to grow up who had not known what work was since the war—people who, if they went on much longer as they were going on now, would never be of any use for work, and would remain a burden on the community for life? The question of which method would be the best to adopt, needed discussing. If anyone had a better plan than his, he would not wish to stand in the way; but nobody up to now had produced a better method. They had to struggle to-day in the markets of the world, with great handicaps. He was not concerned with which firm here got an order; but he was concerned that somebody in this country secured it, and not somebody in another country. ["Hear, hear."] His scheme would help in many directions those who were engaged in industries such as were represented there that evening. The firm he was connected with, who specialized to some extent in large gasholders, had, he was glad to say, a very good order for Montreal, and were engaged on similar business in Toronto. He was pleased, when over there recently, to hear how anxious they were to have British goods. Such work was of great value to this country; and he was certain there was more business of a like kind going in various parts of the world. A scheme like his would enable them to take business they could not get otherwise, and help them to employ again people who otherwise had to walk the streets. They were not working for profits now; most of them were only too glad to cover charges. These were the basic factors which had to be considered; and it was useless to put before him all kinds of hypothetical difficulties regarding his scheme, which he could not possibly solve without an opportunity of trying it. If it did not succeed, then they could stop it. He believed there would be sufficient patriotism and common-sense to enable them to get together and allocate work fairly. They would all be only too glad to work together to see British industry once more placed on a sound basis.

AN APPEAL.

This was the spirit which had animated him in bringing his scheme forward; and he hoped all those who sympathized with him would help him in what was a very difficult task. ["Hear, hear."] There were a great many men who thought that criticism was the only way of assisting; it was not. It was so very easy to criticize; it was so very difficult to construct. He was glad to hear that gas engineers thought they and the members of the Society saw each other too little. He had always thought this himself. Anything he could do to help the Society during his year of office, he would be only too pleased to do. Certainly, he could lay no claim to being a "medicine man;" but Mr. Milne Watson had referred to him in several other capacities—with some he was perhaps not so pleased as with others. In some he was a purchaser of Mr. Milne Watson's products; in other ways he might be a competitor with some of the things Mr. Milne Watson's Company produced. But he knew Mr. Milne Watson would much prefer to see synthetic ammonia and sulphate of ammonia made in this country than that it should be made in Germany; and he would agree that his (the speaker's) Company, in undertaking a very large and daring experiment to make this country safe, in case of another war, in the matter of fundamental explosives, had not been actuated entirely by commercial motives, but also by a deep feeling of responsibility towards the country—a responsibility which naturally came to those who were during the last war in the position of supplying 75 p.ct. of the high explosive, ammonium nitrate, to the Allied forces. They felt that never again should this country be placed in the precarious position in which it was at that time. Of course, he hoped incidentally that they would make some money. He was quite sure British engineering and British science and enterprise were superior to anything which Germany had to offer, even in the lines on which they had been at work for many years. There were here plenty of energy, talent, resource, and inventive capacity; this country was inferior to none in the world in these great qualities. He was not gloomy about the future of British industry, and would never believe they could not re-establish that commercial and industrial position they occupied before the war; or that they were, as many people believed, on the down grade. Take the gas industry, it had been declared dead he did not know how many times; but the declaration had always proved quite untrue. There was more gas sold now than ever before, and the industry would continue to grow in various directions and to improve its processes. He himself had been interested in cheap power for many years; and he had not finished with it yet. They were only waiting for someone to do for gas what the turbine had done for steam, for the swing to be in the other direction.

GAS THE GREATEST SERVANT OF THE PUBLIC.

Sir ARTHUR DUCKHAM, K.C.B., said the honour had been conferred upon him of welcoming their visitors. He had been given a list; but when he read it, he found that the greater number were not really visitors, but were just friends who had come in to join them. The greater part were members of the gas industry; but on rising to propose the toast of "The Visitors," he would wish to welcome the others to a body which was part of a large body that constituted the greatest servant of the public in existence to-day. The industry's work and prosperity were entirely based on service to the public; and he had no hesitation whatever in claiming that the industry was the greatest servant of the public to-day. Just consider what gas meant in the household, in the life of the housewife—how it was lightening the burden in these strenuous times of lack of domestic service. The gas cooker, the gas fire, the gas water heater, and gas-lighting, had made domestic service entirely different; and to-day a situation had been reached in which householders did not at all mind being left without domestics, because they could do the job themselves. To carry the matter further, there was the great service of smoke abatement, in which the gas industry was the chief mover. Smoke had been a disgrace to the country for very many years; and the gas people were those to cure it. It was not super-

tricity stations that were going to do this. The gas industry the one great factor in smoke abatement in this country, and ould continue to be the main factor, by the provision of smokeless , either gaseous or solid. In an amazing speech in the House Commons, the Secretary for Mines had stated that the only hope the Government had in the coal position was the introduction ow-temperature carbonization. When they read this, they must e felt that, even if low-temperature carbonization was right, it st be the gas industry which would have to carry it out, because : was the only industry that could properly handle the busi- s. Going on still further, there was the question of the use gas for industrial purposes. So far they were only touching the ge of what could be done in this direction; but the gas industry ld offer service in this direction which was becoming appreciated re and more day by day. When in America recently, he was ner amazed, while discussing gas and electricity, to be told that gas industry there was going ahead more rapidly than the electri- industry. Gas had a service to render which the electrical industry ld never fulfil. He was entirely of the opinion that the gas in- try had nothing to fear from competition so long as it was fair. ey were not very frightened of the electricity scheme; what they fear was its becoming a burden on the country. The gas industry s one of the principal rate and tax payers of the country; and they re frightened of the possible effect of the scheme on their industry this way, and in this way only. He coupled with the toast the ne of Mr. Hardie, and he would like to say on behalf of the iety that Mr. Hardie was the sort of gas engineer they liked. He was of absolute integrity; he was always willing to see one; and from him they at all times got fair dealing. [Applause.]

THE GAS INDUSTRY'S SUCCESS.

Mr. THOMAS HARDIE, in response, said the visitors appreciated very much the cordial way in which they had been welcomed. The President in his address had dealt with the subject of competition by electricity, and had given to those who were favouring subsidies some good food for thought; but Sir Arthur was right—that gas was not afraid of fair competition. Gas had been in existence over a century; and it was more than fifty years since electrical competition was first put forward to frighten them. At that time it was thought that the uses of gas would be very quickly taken up by electricity; but instead of this, every year increased uses for gas had been found, and to-day there was every bit as much scope for an increase in consumption as was the case fifty years ago. This was shown by the extraordinary growth of demand, even in these years of depression. No other industry had gone ahead at such a speed during the last few years. The gas industry knew it was offering a service which the people wanted; and it did not require to be assisted by subsidies or any other means. The increase in the number of gas-consuming appliances in London alone amounted to thousands weekly; and from this cause arose the increased consumption. This growth in business would continue so long as the industry continued to give a service that the public required. He always enjoyed being the guest of the Society. There was invariably something to learn, and it was very pleasant to meet them all in these happy gatherings.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.

MEETING AT HARROGATE.

THE 201st Quarterly General Meeting of the Institution took place last Friday at the Harlow Manor Hydro, Harrogate, when there was an attendance of about 130. The proceedings opened by luncheon, at which the members and visitors were the guests of the Harrogate Gas Company.

LUNCHEON.

Mr. Francis Barber (Chairman of the Harrogate Gas Company) presided at the luncheon, and was supported by, among hers, Sir Dugald Clerk, K.B.E., F.R.S. (Past-President of Institution of Gas Engineers), Mr. J. H. Ellis (President the British Commercial Gas Association), Mr. F. H. Robin- n (Engineer and Manager of the Harrogate Gas Company, d President of the Manchester Institution), Mr. C. S. Shapley eeds City Gas Engineer, and Vice-President of the Man- ester Institution), Mr. W. B. M'Lusky (Halifax Borough Gas gineer), Mr. Harold E. Copp (Hull), and Mr. W. M. Mason anager of the "B.C.G.A.").

Mr. FRANCIS BARBER, proposing the toast of "The Guests," said Company regarded it as a very great privilege to be able to in- e the members of the Institution to their town—especially so in w of the Institution having graced the Company by the appoint- nt of their Engineer and Manager (Mr. F. H. Robinson) as Presi- nt. Directors of companies realized fully what really important ividuals were the engineers dealing with their great industry; and believed the confidence directors placed in their managers and gineers was very well merited. Institutions of that kind took a y important part in the development of ideas; and he thought whole industry recognized that, of all the scientific minds in the untry, that of Sir Dugald Clerk had probably been among the most pful. ["Hear, hear."] He would like to offer the congratula- ns of the gathering to Sir Dugald Clerk on his recent honour by ng awarded the Medal of the Royal Society. They would all be ighted if Sir Dugald was in a position to let them know something the secrets of some of the recent wonderful results of research at eenwich, of which they had heard lately.

Sir DUGALD CLERK, responding, said on occasions of that kind hnical people did not care much to go into technics; but as Mr. rber had specifically put one point to him with regard to low- nperature carbonization, it would be a breach of his duty if he d not attempt at least a short answer. This question of low- nperature carbonization had been very much in all their minds for ne time; and they were told that the future safety of the country pended on success in that matter. This information was given, he ared, by gentlemen connected with politics who were glad to get ne sort of cry to take to their constituencies. There had always en in politics the need of a campaigning cry to put before the blic. Low-temperature carbonization was just now such a cry.

SUPER-POWER ELECTRICITY STATIONS.

other was that of the super-power electric stations. The elec- cal people were quite good friends of theirs; and the only objec- n he had to their criticisms was when, instead of being criticisms ainst the science of the gas industry, they became personal abuse. he noticed had happened lately in one case in regard to himself. me time ago he offered to discuss matters amicably with the elec- cal people on the floor of their own Institution of Electrical ngineers; the understanding being that if either side was proved rong in their contentions, they would candidly admit it. The esident of the Institution of Electrical Engineers called a meeting r the purpose, and they had a very amicable discussion on the ques- n of whether some of the electrical people's statements as to the lative efficiencies of gas and electricity were misleading to the blic. At the conclusion, the electrical people present accepted his ir Dugald's) arguments without question. Now, however, the ctrical journals were wakening-up to the attack. One had gone so r as to offer rewards to anybody who could show that electrical ergy was not as efficient for cooking and heating as was gas. The urnal, of course, was hopelessly out of it; and the thing only showed how little the writers knew of their business. The electrical engineer of a large city had openly objected to Mr. Baldwin's statement that electricity was enormously too expensive, and that the country would be saved only by getting rivers of electricity and selling it at practically nothing. This gentleman said: "Suppose you put up all the stations that are spoken of, you would not reduce the cost of electricity by one penny." "We know perfectly well," said Sir Dugald Clerk, "that electrical engineers have come pretty near the limit." Sir Dugald referred to a paper which he read some years ago before the North-Eastern Institution of Engineers, when figures were given by himself and by Sir Charles Parsons on the limits of the steam turbine and gas engine. Parsons had said that with steam at 400 lbs. per sq. in., superheated, &c., the maximum efficiency they could hope for was 28 p.ct.; and this was a very high percentage. On a similar comparison as to what gas could do in high-compression engines, his (Sir Dugald's) maximum figure was 46 p.ct.; and, as a matter of fact, in some recent engines that had been built in the North by Beardmore's, they had actually succeeded in getting 40 p.ct. So it was evident the figure was not so far out. Parsons' figures would mean a possible 20 or 21 p.ct. of energy of the coal transferred into current sent out of the station; and one Manchester station of fairly recent construction was doing 20'33 p.ct. "No matter how many super-power electricity stations you put up," said Sir Dugald, "you cannot get 24 p.ct.; and yet we are talking of rivers of electricity at an incredible price!"

LOW-TEMPERATURE CARBONIZATION.

Turning to the subject of low-temperature carbonization, this first appeared about 1906. "My friend the late Sir George Beilby—a very good friend to the gas industry—talked to me when this Greenwich station was started, and asked me to inspect the place; for he felt that the question of low-temperature carbonization should be investigated. Sir George investigated it very carefully; and his view was that, unless you could sell the so-called smokeless fuel produced by this process at an easier rate per ton than the original price of the coal, you could not make the concern pay. That is a fatal objection from our point of view. I have been approached by Government officials, and have investigated the process to which Mr. Barber referred just now; and the results will shortly be published in a report. I can hardly say more on that point at the present moment. On the commercial side, I do not see any real improvement. The great fault is due to this: To take equally good coal, distilled in the low-temperature way, you only get about 5000 c.ft. of gas. Most of the schemes burn that gas to heat their low-temperature retorts. That is idiotic. [Laughter.] I pointed out to the Government people that the most valuable product in gas production is the gas. If you throw away the other things, you cannot expect it to be a commercial success. You must first get the gas right. So far as the oils and tars of low-temperature carbonization are concerned, it was agreed that the products were not so valuable as from high-temperature carbonization. I pointed out that, if the Government desired to get oil for the Navy independent of outside sources, as we all agree is quite desirable, if you can imagine the whole of the 35 or 36 million tons per annum in Great Britain (I think 36 million is the figure stated, but I have recently found it is only 35 million) being put through low-temperature carbonization, and take the latest yield of oil by the most approved process, you would have about one-third of the amount required by the ships of the British Navy using steam power. If we had all the Navy using internal combustion engines, we should just be able to keep our ships going by the oil got by that low-temperature carbonization. If the Government approach this matter from that point of view, it is quite legitimate for the Fuel Station to continue experimenting. I do not expect they would attain commercial success; but they may get a knowledge which will enable us, in case of war, to feed our ships with oil—a course of which we all fully approve."

Mr. J. H. Ellis, submitting "The Institution of Gas Engineers," said it was a great pleasure to him to propose a toast to an organization to which all placed as he was—as Chairman and Managing Director of a large gas undertaking—owed so much. He doubted whether there was any institution in the country so full of good fellowship, sound knowledge, and business ability as the Institution of Gas Engineers; and he doubted whether there was any endowed with such a high sense of public duty and responsibility. They would not expect him, following Sir Dugald Clerk, to deal with matters from the technical side; but he might be able to say something of them as they presented themselves to him as a man of business. Most Yorkshiremen knew Mr. Lane Fox, the present Minister of Mines, as a great Yorkshireman, a great landed proprietor, and a good sportsman. They were glad to hear him in those capacities; but his sentiments on the subject of low-temperature carbonization he (Mr. Ellis) ventured to say were entirely wrong. They had just heard what Sir Dugald Clerk had said as to its likelihood of being a commercial success. Yet Mr. Lane Fox, in the House of Commons recently, said: "The Government were going to spare neither money nor energy to make this process a commercial success." That was absolutely unfair, improper, and uneconomic. ["Hear, hear."] Yet it came from the mouth of a Conservative Minister. "I know something, second-hand, perhaps, about low-temperature carbonization," said Mr. Ellis. "Let me draw attention to what a man highly respected in the North for his knowledge and his position said in a letter to 'The Times'—a letter written long before Mr. Lane Fox's utterance. Lord Gainford stated therein: 'It is now over twenty years since this process was first brought to the notice of the public.' It has been investigated, experimented upon, modified, and transformed in at least fifty varieties of ways. The highest technical skill has been exercised upon it; laboratories have been devoted to the most elaborate researches into the possibilities of its development. Over £1,000,000 has been expended in the effort to give this phantom a body and a shape; and yet we have found no convincing solution of the problem which surrounds it.'" With that warning before him, said Mr. Ellis, Mr. Lane Fox stated that "the Government are going to spare neither money nor energy to make this process a commercial success." It was objectionable on business grounds. Several years ago his Company at Plymouth tried this process under its then name of "Coalite." A free hand was given for the trial; and the experimenters cleared out because it did not pay. The resulting product of fuel, which was to be smokeless, would not burn. That was the experience twenty years ago. He quite agreed that one failure was not sufficient for engineers to accept as final. They no doubt wanted to try it themselves; probably a good many present had tried it. He knew that some people, at any rate, had given the low-temperature carbonization people an opportunity to see if they could make a success of it. He knew this because some little time ago there was a paragraph in the papers that Nottingham had actually made a success of it. A friend of his came to him for information and guidance, thinking he would like to put some money in it. He told him to come back in a week. Meanwhile, he made inquiries. When the friend came back, and still seemed interested, in spite of the result of the inquiries, he told him to go and see the works at Nottingham, but he fancied he would find they were not there. He made further inquiries at Nottingham, when he heard the Government were going to take this thing over, and was informed that not a brick had been laid. In the Technical Press recently he read a paragraph reporting a claim before Mr. Justice Greer, in the King's Bench Division, against Low-Temperature Carbonization, Ltd., for compensation in default of erection of their plant; and judgment was given for the amount claimed, with costs. This was the latest information that he had as to low-temperature carbonization. [Laughter.]

THE ELECTRICITY SUBSIDY QUESTION.

Passing to the commercial aspect of the electricity subsidy question, Mr. Ellis quoted from the "Yorkshire Post" of that day a letter by Mr. C. Nelson Hefford (the City Electrical Engineer of Leeds)—a letter which was so full of sound sense and fact that he readily adopted it. It was addressed from the Whitehall Road Works, Leeds. Mr. Ellis said he only hoped the knowledge at Whitehall Road, Leeds, would extend to Whitehall, London. [Laughter.] The letter was a long one, but very sound, and in conclusion summed-up the matter as follows: "Electric current is to-day generated almost as cheaply as existing knowledge and existing economic conditions permit. In the industrial North, at any rate, the pressure of circumstances is automatically resulting in interchange and co-operation between the larger producers. Politicians should beware lest, even with the best intentions, they retard rather than advance progress." Mr. Hefford was evidently man enough to say, "I will fight my competitors unfettered," and they of the gas industry said the same. ["Hear, hear."] Frankly, he distrusted the Government—not in a political sense, but in dealing with matters of this kind, because of lack of knowledge, because of the economic position, because of the danger of unfairness in other directions.

Mr. Charles Wood, responding to the toast in the unavoidable absence of Mr. J. Ferguson Bell, said they had listened to two excellent addresses by Sir Dugald Clerk and Mr. Ellis. He was sure what the speakers had said was most important at the present time; and the information they had given would have a very good effect on all of them. Mr. Wood remarked that he himself had been a member of the Institution of Gas Engineers almost more years than he cared to remember, and he had been a member of the Manchester Institution even longer. He believed he was the fourth or fifth oldest member of the Manchester District to-day.

Mr. C. S. Shapley, proposing "The Chairman and Directors of the Harrogate Gas Company," expressed the warm thanks of all for the hospitality received, and to Mr. Robinson for the trouble he had been to in making the arrangements for the visit. Mr. Shapley said he was sure the members would find a great deal to interest them at the Harrogate Gas-Works, where Mr. Robinson had a good many rather novel ideas in operation. With regard to the letter by the Leeds Electrical Engineer, Mr. Hefford was "a jolly good electrical engineer, and a clean fighter." There were few better electricity works than those at Whitehall Road, wh they were producing electricity at an average selling price of 1·5 The gas undertaking was "up against it;" but it stiffened it backs, and would do good. But it was grossly unfair that, app ently, they were not to come in for a bit of the spoil from the G ernment which was to be given to the electrical people. The industry was supposed to have done yeoman service in the war; it seemed now as though the electricity industry was to be ass by the State, and the gas industry was to be left to plough lonely furrow.

Mr. F. Barber, responding, said he was glad such tribute been paid to Mr. Robinson. It was really more an honour to Robinson than to the Company that the members had come to H rogate that day. It was the Company's esteem for their Engi who was the Institution's President, that had induced the Direct to support the high honour the Institution had done him; and t were glad to be able to show their appreciation. Mr. Robinson appointed eleven years ago; and their selection of him had more than justified by the results to the Company during this pe and now by the honour brought to them through his electio President of the Institution.

Mr. F. H. Robinson expressed his appreciation of the kind th that had been said about him.

THE BUSINESS MEETING.

At the business meeting, which was held in the ballroom the Hydro, the members were briefly and formally welco by Mr. Barber. Mr. Robinson was in the chair.

Mr. Mason, by special permission, shortly outlined the nat of the new Wembley Gas Exhibit, its aims, and the indust hopes of it; stating that it was even better than last year, backed by still better publicity, and was the centre of very g hopes for what it could do in showing the world all that could accomplish for industry and for the home. He ur support of the exhibit on the part of any gas undertaki which had not yet given that support. Referring to extr gant and unjustified claims for electricity, Mr. Mason some people thought the "B.C.G.A." ought to rush into p to controvert all the misleading statements which appea but it had been found to be by far the better way not to e into controversy, but to concentrate on widespread publi of the capacities of their own product, gas. The way to business was to concentrate on that business, rather tha conduct newspaper controversy for the public amusement.

On the motion of the President, the meeting passed a r lution of condolence with the relatives of the late Mr. E Brockway, of Cleethorpes.

Mr. W. B. M'Lusky (Halifax) then opened a discussion the following subject:

SPECIFICATIONS FOR INTERNAL FITTINGS.

The Halifax specification is as follows:

SPECIFICATION AS TO THE CONSTRUCTION AND PLACING INTERNAL PIPES, METERS, AND FITTINGS.

Sections 36 and 37 of the Halifax Corporation Act, 1 read:

As to Construction and Placing of Pipes, &c., Betwee Mains and Meters.

36. In order to enable the Corporation to ensure a satisfa supply of gas to their consumers, the following provisions shall effect:—

(1) The Corporation may specify the size and material of the with the fittings thereof which are to be laid by the cons *on his own premises* either in the first instance or on the sion of any renewal between the Corporation's mains and meter so far as such pipes and fittings are intended to be co over.

(2) The Corporation may, if they think fit, make different spec tions for different classes of premises, having regard to probable maximum consumption of gas thereon at any one

(3) The specification shall be published once in each of two papers circulating within the limits of supply, and a copy th shall be kept exhibited in the office of the Corporation.

(4) Every meter to be used in a new building or a building previously supplied with gas, or in connection with a ne substituted pipe laid by the consumer between the main an consumer's meter, shall be placed as near as reasonably pra able to the Corporation's main, but within the outside wa the building.

(5) When any such pipe or meter as aforesaid has been laid or pl notice thereof shall be given to the Corporation, and the shall not be covered over until the expiration of twenty hours from the service of such notice on the Corporation. officer of the Corporation duly appointed may between o'clock in the morning and five o'clock in the afternoon a and inspect such pipes with their fittings and meter; and i officer is not permitted to make the inspection, or if the or fittings are not according to the Corporation's specifica or if the meter is not placed as required by this section Corporation may refuse to supply gas to the premises until provisions of this section have been complied with.

(6) Any person to whom the Corporation refuses a supply of under the provisions of this section may appeal to a sessional court against such refusal, and the court may, hearing the parties and considering any questions as to reasonableness of the Corporation's specification, make order as seems to them proper in the circumstances, and

order by which of the parties the costs of and incident to the appeal shall be paid.

GAS CONSUMERS TO GIVE NOTICE TO CORPORATION BEFORE REMOVING.

At least twenty-four hours' notice shall be given to the Corporation by every gas consumer, either personally at the office of the Corporation or in writing, before he shall quit any premises supplied with gas by meter by the Corporation, and in default of such notice the consumer so quitting shall be liable to pay to the Corporation the money accruing due in respect of such supply up to the next usual period for ascertaining the register of the meter on the premises or the date from which any subsequent occupier of the premises shall require the Corporation to supply gas to such premises, whichever shall first occur. Notice of the effect of this requirement shall be endorsed upon every demand note for gas charges payable to the Corporation.

Length of Service Provided Free.—A service pipe will be laid from any existing main to the boundary of any private property on request free of charge, provided the length of service pipe required is not greater than 30 ft. Any additional length of pipe required to reach the boundary, and all piping laid in private property, will be charged to the consumer or owner of the property, as the case may be. No gas piping must be built in.

Lead Pipes and Connections to Inlet and Outlet of Meter.—A soft lead pipe connection between the end of the iron service pipe and the inlet to the gas meter must not be less than 12 in. or more than 36 in. in length. No outlet pipe from the meter—however small—must be less than $\frac{3}{4}$-in. internal diameter. Union joints, whether on the main tap or on the outlet of the meter, must not be "bull-nosed" or "branched" on the side, but must be joined to the end of the pipe. In cases where lead connections are to be made to wrought-iron piping, a brass union and tailpiece must be used.

Application for a Supply of Gas.—Application for a supply of gas, whether in respect of premises not supplied previously or in case of change of tenancy, must be made at the Gas Showrooms, Waterhouse Street, Halifax, or at the Borough Treasurer's Office, Town Hall, Halifax, when, subject to the regulations in respect to deposits and the requirements of the Corporation as to the soundness and suitability of the pipes and fittings within the premises, the supply will be given.

Fitter.—All gasfitting work should be done by an experienced gasfitter (hereinafter described as the fitter).

Maximum Number of Burners and Appliances.—Before commencing any gasfitting work, the fitter must give notice to the Gas Engineer of the number of lights and/or gas appliances intended to be fixed.

Inspection and Testing of Gasfitting Work and Tenants' Fittings.—The service pipe will then be laid and the meter fixed; but the gas supply will not be turned on at the meter by the fitter until the fitter has personally examined the pipes and fittings and satisfied himself that the work is sound in every respect, and in accordance with the regulations of the Corporation. He must then intimate to the Gas Engineer (on a form provided for the purpose) that the work is ready for testing, whereupon the pipes and fittings will be examined by the Gas Department's inspector (hereinafter described as the Inspector). If the work is found satisfactory, a certificate to that effect will be issued; otherwise the fitter must at once remedy the defects, and, when he has done so, notify the Gas Engineer, who will arrange for a second inspection.

Notification of Additional Lights or Appliances.—If at any time after gas has been supplied to premises it is desired to add, remove, or alter the position of any light, fitting, appliance, or meter, notice of such intention must be given by a fitter to the Gas Engineer at the Gas Showrooms, Waterhouse Street, Halifax, whereupon the premises will be inspected; and if such additions, removals, or alterations are approved, the necessary permission to commence the work will be given with or without conditions attached.

Meters on Sale or Hire.—Meters may be obtained from the Corporation on sale or hire.

Meters to be Tested.—Consumers' own meters, whether new or old, must be sent to the Gas-Works, Mulcture Hall Road, Halifax, for approval before they can be fixed, and each meter when sent must be accompanied by a note giving the full name and address of the owner. Any meter not so approved must not be used.

Secondary Meters.—Meters supplied on hire by the Corporation must be used only for the measurement of the whole supply of gas used. Other meters required by the consumer for the separate measurement of gas used in different parts of the premises are not provided on hire by the Corporation. Schemes and estimates for the sub-division of the gas supply within any premises will, however, be prepared and supplied free, upon application at the Gas Showrooms, Waterhouse Street, Halifax.

Size of Meter.—The size of the meter required at any premises will be determined by the Corporation on the basis of the maximum demand.

Position of Meter.—The meter must be fixed in a level position at a sufficient height from the floor to prevent lodgment of water around it. The position selected should be near the wall abutting on the street in which the gas main is laid, but not near a fireplace or boiler, and not in any position which is inaccessible or dangerous.

Protection of the Meter.—A space of 3 ft. must be provided between gas meters and electricity meters.

Safe Distance Between Gas and Electricity Supplies.—Where gas and electricity supplies are to be used on the same premises, the gas pipes must not be fixed at a less distance than 1 ft. from the electricity wires.

Types of Meters.—Wet meters have been found more suitable in most of the positions in which gas meters are fixed in Halifax; but in dry situations dry meters may be fixed. Such meters, however, must be placed on a shelf or other support provided by the consumer.

NOTE.—In all cases the pipe must be laid with sufficient fall towards the meter.

Meters for Gas Engines and Other Special Purposes.—Specifications and estimates will be furnished on request by the Corporation for meters required for the supply of gas to engines, furnaces, and other special appliances.

Consumers' Governors.—Consumers' governors are recommended. All such governors must be fixed on the outlet of the meter. Where mercurial governors are used, provision must be made to prevent any mercury getting into the meter.

INTERNAL PIPES AND FITTINGS.

Shops, Workshops, Factories, Warehouses, Offices, and Business Premises Generally.—The size of the outlet pipe from the meter will be determined by the maximum demand of the installation.

Residences.—The upright pipe from the floor must in no case be less than $\frac{3}{4}$ in.

2 to 4 rooms	..	$\frac{3}{4}$ in.
5 to 7 ,,	..	1 in.
8 to 12 ,,	..	$1\frac{1}{4}$ in.
13 to 16 ,,	..	$1\frac{1}{2}$ in.

Size of Outlet from Meter.

Wrought-iron pip to be used.

The above dimensions must be adhered to generally, but where a larger supply of gas is necessary, a special specification will be provided by the Corporation. The size of pipe specified above must be carried to the first branch, and from that point forward in accordance with the following Tables.

Table Regulating Size of Branch Pipes and Maximum Number of Burners.

Material.	Size.	Greatest Length Allowed.	Number of Burners.
	In.	Ft.	
Block tin, wrought-iron, lead, or tinned composition.	$\frac{3}{4}$	20	3
		30	6
		40	12
		50	20
	1	70	35
	$1\frac{1}{4}$	100	60
	$1\frac{1}{2}$	150	100
	2	200	200

NOTE.—No pipe of less than $\frac{3}{4}$ in. internal diameter is allowed.

Particulars of pipes required for larger installations will be supplied on application.

Weights of Various Sizes of Interior Piping.—Piping used for gasfitting must be of a quality approved by the Corporation, and of not less than the following weights:

Internal Diameter of Pipe.	Weight per Foot.			
	Block Tin.	Wrought Iron.	Lead.	Tinned Composition.
	Lbs. Oz.		Lbs. Oz.	Lbs. Oz.
2 in.	..	"Gas" strength for internal fittings only.	7 4	7 4
$1\frac{1}{4}$ in.	..		4 $10\frac{1}{2}$	4 $10\frac{1}{2}$
$1\frac{1}{2}$ in.	..		3 5	3 5
1 in.	0 11		2 0	2 0
$\frac{3}{4}$ in.	0 7		1 4	1 4
$\frac{1}{2}$ in.	0 4		0 $14\frac{1}{2}$	0 $14\frac{1}{2}$
$\frac{3}{8}$ in.	0 3		0 $7\frac{1}{2}$	0 $7\frac{1}{2}$

Minimum Internal Diameter of Pipes for Various Purposes.

	In.
For a single or double bracket or pendant	$\frac{3}{8}$
For a bracket or pendants with a continuation for a gas iron or other small gas appliance	$\frac{1}{2}$
For a boiling burner or griller	$\frac{1}{2}$
For a fire in a small or medium-sized room	$\frac{1}{2}$
For a fire in a large room	$\frac{3}{4}$
For a small cooking stove	$\frac{3}{4}$
For an ordinary cooking stove	$\frac{3}{4}$ or more, according to the size of the stove.
For a small washing copper	$\frac{1}{2}$
For geysers and water heaters.	$\frac{3}{8}$ or more, according to the size of the appliance.

NOTE.—When a cooker and a washing copper are taken from the same branch, the branch must be not less than $\frac{3}{4}$ in.

Particulars for gas engines and other larger appliances will be furnished on application.

Fittings for Cooking and Heating Appliances.—Lead or wrought-iron supply pipes must be used for the supply of gas to cooking or heating appliances. The bore of the tap must

be equal to the bore of the pipe. The supply must be taken from a pipe of sufficient size, and direct from the meter outlet if necessary. Brass or copper tubing used in connection with gas fires or for other purposes must be solid drawn.

Anti-Fluctuators to be Attached to Gas Engine Supplies.—In all cases where gas engines are fitted, an efficient anti-fluctuator approved by the Corporation must be fixed.

Self-Acting Syphons Not Allowed.—Self-acting syphons must not be used.

Stopping Pipe-Ends.—Wooden plugs must not be used for stopping pipe-ends.

Joints.—The whole of the fittings and piping must be gas-tight and stand a test of pressure equal to 10 in. water-column for a reasonable time. Rings for making joints must be formed either of asbestos or lead, with flax or hemp and red lead packing. Indiarubber rings must not be used.

Gasfittings.—Pendants must be fixed with a trimmer, bolt, back nut, and elbow union, and with a pattress between the end of the pendant and the ceiling. Connecting bits must not

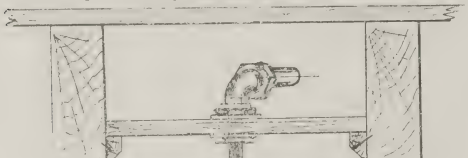


Fig. 1.—Fixing with Trimmer, Bolt, Backnut, and Elbow Union.

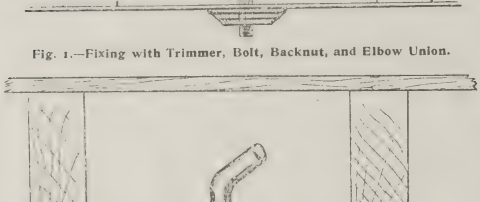

Fig. 2.—Showing Connecting Bit.

be used. The pendant top, pattress, and trimmer must be efficiently screwed together.

NOTE.—Water-sealed gasoliers must not be used. Ball-and-socket joints of the half-ball variety must not be used. All fittings must be produced on demand for inspection and approval by the Corporation.

Side Brackets.—Side brackets must be fitted with brass connecting bits, and fixed on wooden blocks let into the wall.

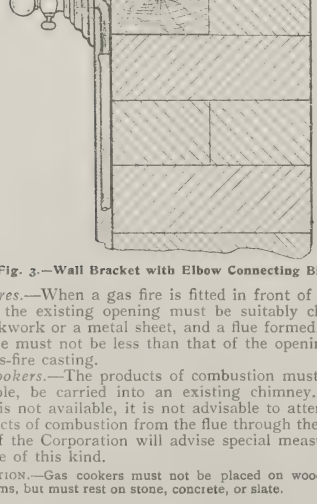

Fig. 3.—Wall Bracket with Elbow Connecting Bit.

Gas Fires.—When a gas fire is fitted in front of an existing fireplace, the existing opening must be suitably closed either with brickwork or a metal sheet, and a flue formed. The area of the flue must not be less than that of the opening provided in the gas-fire casting.

Gas Cookers.—The products of combustion must, if it is at all possible, be carried into an existing chimney. Where a chimney is not available, it is not advisable to attempt to lead the products of combustion from the flue through the wall. The officers of the Corporation will advise special measures to suit every case of this kind.

CAUTION.—Gas cookers must not be placed on wooden floors or platforms, but must rest on stone, concrete, or slate.

Precautions to be Taken in Case of Escapes, &c.—When th odour of gas is first detected, the gas supply must be turne off at once at the main tap *near the meter*, and the window opened at the top and bottom. All fires and lights in the pre mises affected must be extinguished, and no attempt must b made to search for the escape with a naked light. Night call are received at the Gas-Works, Mulcture Hall Road, Halifa (Telephone No. 1485), and prompt attention will be given at al times. The Corporation will not be responsible for any los or damage caused by leakage in internal pipes or fittings.

Unauthorized Persons Not to Interfere With Pipes, Taps, &c —Apart from cases of fire, escape of gas, or other emergency no meter, service pipe, or *service-pipe tap outside any premises* must be interfered with by any person not in the employmen of the Corporation Gas Department.

The above notes were taken as read, but in introducing them Mr. M'Lusky said he had found that the Manchester district was very well in advance of the country generally in this matter. As far back as 1891 the Corporations of Bradford and Burnley had powers to ensure efficiency of gas pipes and fittings, and to prevent accidents. Statements of particulars as to the materials to be employed, the mode of their use or construction, and the soundness of the craftsmen's work when finished, had been provided by gas undertakings in various parts of the country for many years past. One of the best specifications was that of the Manchester Corporation. The work of the Manchester Corporation Distribution Department appeared to be organized right down to the last holdfast. The following sections in the specifications in the hands of the members in print were taken from the Manchester specification: Lead pipes and connections. Position of the meter—with this difference, that in the Halifax section it was provided that the meter should be near, and not against, the wall, as they had had meter cases destroyed by stray currents of electricity earthing between the damp wall and the case of the meter. Weight of pipes. This section was based on the practice in Manchester. Hitherto the weights of lead pipes used in Halifax had been heavier than the lead pipes in Manchester; but, on the other hand, the Halifax weights for tin pipes were less than those of Manchester. Gasfittings and side brackets. Here the particulars were substantially as those of the Manchester Corporation. In all other particulars the specification was the result of his own experience.

For half-a-century or more, he said, the work of internal fitting for gas supply had been conducted in accordance with a well-established rule and practice in the principal towns in this country, at any rate. The Burnley Borough Improvement Act, 1871, gave the Burnley Corporation the following powers: "All pipes and other fittings required for distributing gas or water respectively within any building shall be approved of by and affixed to the satisfaction of, the Corporation or their gas or water manager respectively, before the owner or occupier of such building shall be entitled to a supply of gas or water."

The Oldham Improvement Act, 1880, section 52, provided among other things, that "the Corporation may, if requested by any person supplied or to be supplied by them with water or with gas, furnish to him at his costs and charges, and from time to time fix, repair, alter, or add to, any pipes, valves, meters, &c., . . . or . . . any gasfittings necessary for or connected with such supply, and may provide all materials and do all works necessary or proper in that behalf, or instead of charging the costs thereof to such person may charge such person with such annual or other rent or sum as may be reasonable and agreed on between the Corporation and such person."

The Bradford Water and Improvement Act, 1881, section 45 for ensuring efficient gas and water pipes for houses, stated: "The Corporation may from time to time make and publish such bye-laws as they deem necessary for securing the laying, fixing, and fitting of pipes for the distribution and supply of gas and water by the Corporation at houses and other buildings and places in the borough [Bradford was not at that time a city] in a proper and efficient manner and by competent persons only, and for granting license and authority to such persons for such purpose." The remainder of the section provided penalties to be imposed on persons who acted contrary to the by-laws, or persons not so licensed who fixed, repaired, or altered any pipe or fitting. The Bradford Water-Works and Improvement Act, 1885, section 31, empowered the Corporation to lay and fix service pipes, taps, fittings, junctions, connections, chandeliers, brackets, and the other appliances connected with the supply of gas by the Corporation, at houses and other buildings and places in the borough, and regulated the size and quality thereof.

The Burnley Corporation (Tramways), &c., Act, 1898, provided regulations for preventing the misuse of, and accidents from, gas. Section 35 of that Act read as follows:

"For preventing misuse of gas and for preventing accidents in connection with the supply of gas, the following provisions shall have effect:

"(1) The Corporation may make such regulations as they think necessary for the objects aforesaid to be observed by persons supplied with gas.

"(2) By any such regulations the Corporation may direct the use and prescribe the size, nature, strength, and materials, and the mode of arrangement, alteration, and repair of pipes, valves, meters, and other apparatus to be used by such persons re

spectively for carrying, delivering, and receiving gas, and may interdict any arrangement and the use of any pipe, valve, meter, burner, or other apparatus in their judgment likely to occasion misuse of gas or likely to cause accident.

(3) The Corporation shall not be bound under any agreement or otherwise to supply, or continue to supply, gas to any person unless such regulations as are for the time being in force are duly observed by him."

The Bradford Corporation Act, 1903, section 35, the Perth Corporation Gas Order Confirmation Act, 1906, section 10, the Oldham Corporation Act, 1909, section 70, and the Halifax Corporation Act, 1920, section 36, provided powers to enable the Corporation to ensure a satisfactory supply of gas to the consumers; and with one or two unimportant exceptions, these orders were alike in expression. The more recent Orders omitted the publishing of the specification to one insertion in one newspaper, instead of two insertions as in the earlier orders. Section 5 of the Bradford Order began: "When any such pipes, meter, or fittings as aforesaid." The other Orders referred to omitted the word "fittings" in this part of the section. But the inspection of fittings was provided for in all cases in a later part of the section. Powers or Acts were not lacking; and if any undertaking to-day was short of powers, the remedy was at hand in the Gas Regulation Act.

Mr. M'Lusky said he supposed the discussion that afternoon would probably centre on the need for the better exercise of the powers undertakings already possessed. Time was when excuses could be made for lack of progress in fittings work, or the inspection of fittings; but to-day he thought no fault could be found with the master fitter or his men. They were, a large extent, the agents of the undertakings; and his experience was that they were good agents, and they were always ready to do what was required of them. It was desirable that specifications should conform to an accepted standard. If a specification was good enough for one district, it was good enough for the country, or, at any rate, for an area such as that covered by the Manchester District Institution of Gas Engineers. It was true that practice varied to some extent in different parts of the country. Lead service pipes were used in preference to other materials in parts of the North of England, and in the South-Eastern districts of Scotland. Block tin tube was preferred to tinned composition in many cases, and in Yorkshire ordinary lead pipe was used in preference to wrought iron to a large extent; but a general specification such as that submitted by him that day covered this range. It was a general specification. The working out of the minor details—which were purposely omitted—was better left to the initiative and experience of those who had to do the work, and who knew their own peculiar requirements.

Specifications, after all, did no productive work; but as part of the organization the specification was indispensable. The organization, of course, included the architect first and foremost, the builder, the master fitter, and the gas authority and its administrative and executive staffs. In an organization of that kind the specification became a mere "finger-post" or direction sign—everyone observed it, everyone worked to it, with the result that the architect's schedule of quantities provided a uniform basis of tender, and the architect proceeded with the regularity of a fixed habit. The importance of gasfitting work had probably of late years escaped the notice of the general fitter, the master plumber, the sanitary engineer, and the occasional electrical fitter, who had relegated gasfitting to the position of a mere branch of his general business, and in some cases, he feared, a much neglected branch.

During the past ten years, Mr. M'Lusky concluded, apprentices engaged in such general work had, in many cases, had little or no real gasfitting work in the whole course of their training. This was bad for the craftsman himself, and, if the remedy were not applied, would react on the industry. In Halifax the training of apprentices was one of the responsibilities of the Distribution Superintendent, and the training consisted of the art and craft of meter-making, sheet-metal work, and gasfitting.

Discussion.

Mr. RALPH HALKETT (Sheffield) said his Company at Sheffield had no power to specify pipes, but they did keep in touch with the builders. This had been in operation for some time, and was found to be very beneficial to the Company and to builders alike, because it had helped to get fittings into houses where people would not let them take-up boards and run pipes to instal gas fires. They had only recently adopted prepayment meters in Sheffield, and they specified that certain pipes should be run through. This was absolutely necessary, because they found the difficulty was with old houses. If the plumber thought he would put in a pipe, he sometimes did not mind what sort of pipe it was. The difficulty in these old houses was, therefore, to get sufficient pressure of gas through the pipes previously put in by plumbers. It was certainly a very happy position to be in to be able to specify what pipes should be installed; but he was afraid not many undertakings were in it. Now that they were going to have such keen competition from the electricity people as they had expected, it was up to them all to see that, if they had not powers, they should get into touch with builders and architects, and educate them to the needs of gas service. Another useful channel was that of good relationships with the local plumbers, who also should be educated to the requirements of gas appliances. In regard to service, he noticed Mr. M'Lusky defined 60 ft. free to the boundary. In Sheffield they gave 20 ft. to the mains, no matter what was the position. Mr. M'Lusky referred to wet meters. In Sheffield they were happy in having all wet meters. From his experience, he would never think of going over to dry meters. The wet meter seemed to him certainly more reliable, and it also provided a saving in the cost of repairs.

Mr. HAROLD E. COPP (Hull) said he must confess he was a little alarmed at the statement that so very few fittings in houses would stand any test. He thought the reason would be found to be the bad fittings, rather than the pipes themselves. A very large number of fittings coming under his notice showed minute leaks at the taps; and he thought this was one of the principal causes of the trouble. It behoved them to get their fittings as tight as possible. The way he had overcome the matter at Hull, having no statutory powers, was by selling to the fitters from the undertaking's own stock. For what fittings from that stock that were put in by the outside fitter, he was charged only 5 p.ct. on the Company's actual cost price. The fitter therefore preferred to come to the undertaking, and they saw that he got good fittings.

Mr. H. DAVIES (Chesterfield) believed the Manchester Institution were instrumental in preparing a specification of this kind some years ago; and he thought it was still fairly up-to-date. If not, he would suggest it should be made so. He believed that before very long the industry would be required to carry out this phase of work with the utmost possible precision. With regard to the 24 hours' notice which consumers had to give, Mr. M'Lusky said it must be given either in writing or by a call at the office. Did he find any difficulty in people calling at the office and not giving notice in writing? In regard to the fitters, were they Corporation fitters or local plumbers? He found it extraordinarily difficult to insist in every case on having a meter fixed as Mr. M'Lusky suggested it should be done, though the local by-laws said it should be done in that way. He fancied, if they insisted too much, they would get no gas at all into some places.

Mr. W. W. ATLEY (Stockton), President of the North of England Association, said he had had a complaint only that day from a consumer, who asked what was their standard pressure. The consumer said that before putting on a cooker he got 6¾ in. water gauge, and on the cooker being put on the pressure dropped to 6 in. Upstairs, for a water boiler, the pressure was only 4 in. The reply sent to him was that the standard pressure was 2 in. water gauge; and if he was getting 6 in., he was getting three times more than that. As to the inequality upstairs, he should get a local plumber to make it right. Mr. Atley said his undertaking had a Bill going through Parliament, by which they would have powers to provide, if they so desired, a specification for internal pipes; but there was so much red-tape attached to it from a municipal undertaking point of view, that he, personally, was not anxious to be the instigator of preparing the specification. At Stockton, owing to local conditions and bargaining, they were very generous in free service pipe, giving up to 50 ft. from the main. It used to be 30 ft. He had a complaint recently of a plumber who had fixed a gas fire for the undertaking, under a scheme which they had with the plumbers; and the complaint was that they could get no gas to it. On investigation, it was found that the solder had run right through and blocked-up the pipe. Mr. Atley thought the undertakings, however, should foster as much business as they could with local plumbers; and in Stockton they had a standard price for fixing fires up to 30 ft. from the main. Anything beyond this was paid for by the consumer at so much per foot. They allowed the fitters half the year's hire on the fire, as a commission for their help in getting the business.

Mr. W. M. CARR (Stretford), referring to loss of pressure when testing, said it seemed to him that they ought to be able to obtain powers such as those held by the water undertakings, to enable them to stamp appliances and fittings. If they made sufficient representations to the Board of Trade, such powers would eventually be given them. That they were very necessary was borne out by what Mr. M'Lusky said. He knew this was not a new suggestion, but he thought they ought to try to bring it about.

The PRESIDENT said, regarding the powers of undertakings to make these specifications and enforce them, the Bedford Gas Company had recently got authority to specify and enforce. They in Harrogate, in an Order received from the Board of Trade, which was now before the House of Commons, had similar clauses; and it seemed to him that if other undertakings applied to the Board of Trade, they should have no difficulty in getting them. At Harrogate they had been working on the Manchester specification for some time. He agreed with Mr. Carr that power should be given to insist on a higher standard of work, such as water undertakings possessed. It was a matter of both satisfaction and safety to consumer and supplier alike.

Mr. A. E. MOTTRAM (Ossett) asked that the discussion, which was on a subject of great interest, should be adjourned to the next meeting, to be renewed on that occasion; and this was agreed to.

Mr. HALKETT said some observations made prompted him to add that the installations put in by the builders in Sheffield were subjected to a test of 4 lbs., and had to stand for half-an-hour. He found there was no difficulty in getting pipes to stand the 4 lbs. pressure; but it would be very difficult to get some fittings to stand it.

Mr. M'LUSKY said he would reserve a detailed reply, in view of the renewal of the discussion on a future occasion; but there were one or two points to which he might refer. He agreed with Mr. Halkett and Mr. Copp. There was no difficulty with regard to pipes, joints, or the work of the craftsman on the job. The whole of the difficulty was with the fittings. At Halifax they were wholesale distributors, and they found they had to reject a good many fittings, even from a house of good repute. They had reason to adhere to the letter of the specification. They did not take the responsibility of laying pipes in private grounds. The pipe was the property of the owner of the grounds, and he was responsible in the event of leakage. From the main to the meter they charged only once. Their fitters were registered. They had a co-partnership scheme with all fitters in the town who were qualified to be registered. The fitters got the whole of the difference between the invoice price and the sale price; the gas undertaking got nothing in that respect. If the gas undertaking made the sale, it had all the profit.

The scheme was an inducement to the fitters to come to the undertaking to buy. In Halifax they found the architects and builders had been habituated to work with the undertaking. The undertaking's men were always in contact with them, and they got to know when an installation was required, and it was simply booked. As to the suggestion of stamping, the clauses he had quoted amounted to the equivalent of powers to stamp.

On the motion of Mr. G. S. Frith (Runcorn), the thanks of the meeting were accorded to the Harrogate Gas Company for their hospitality, and to Mr. Robinson for all he had done for the members throughout the day.

Mr. Robinson briefly acknowledged the vote.

The party were then conveyed to the Harrogate Gas-Works, where tea was subsequently served.

NEW HOLDER AT ROMFORD.

Inauguration Ceremony.

With the recent inauguration ceremony in connection with a new boiler at the Romford Gas-Works, the completion was reached of twelve months' work; the foundations of the tank having been laid in April, 1924. The opening of the valve to admit the first gas to the holder was performed by Miss Ellen Johnson, the daughter of Mr. Henry Johnson, who is Chairman of the Company. The new holder has a capacity of 1½ million c.ft., and was constructed by Messrs. Westwood & Wrights, Ltd., of Brierley Hill.

Mr. Johnson said the reason that the Company decided to have the holder was because the output was a million c.ft., and the storage was only half a million, which was the cause of much work and anxiety to the officers. The new holder would make the work easier and give better pressure to the extremities of the district. The Hon. Charles Rhys, M.P. for the Romford Division, referred to the growth of the neighbourhood and the necessity for the enlargement of the undertaking. When Miss Johnson had opened the valve, he, on behalf of the Company, asked her to accept a gold wrist watch and bracelet as a memento of the occasion. On this was inscribed: "Presented by the Romford Gas Company, Ltd., to Miss Ellen M. Johnson, daughter of the Chairman, upon the opening of the new gasholder, May, 1925."

The party then adjourned to the Board Room, where the Chairman proposed success to the new holder, coupled with the names of Messrs. Westwood & Wrights and the Company's General Manager, Mr. Frank Wright. With the toast was coupled also the name of Mr. Robert Wyld (the Foreman Erector).

Responding, Mr. Wright (of Messrs. Westwood & Wrights) said the new holder was a three-lift spiral guided one; the tank having a capacity of 15,589 tons of water. It was 147 ft. 6 in. in diameter by 33 ft. 3 in. deep, and weighed 337 tons. It contained 750 plates, 1 in. to ¼ in. thick, and was held together by 68,000 rivets. The holder bottom lift had a diameter of 145 ft., the middle lift 142 ft. 6 in., and the inner lift 140 ft. There were 328,400 rivets used in its construction. Proceeding, he asked Miss Johnson, on behalf of the firm, to accept a cut-glass rose bowl, made at the glass works almost next door to his firm's premises. Referring to the gasholder, he added that, without the full co-operation of the staff and men at the works and on the site, it would have been impossible to carry out such a contract successfully. That such a holder was required to deal with the gas consumption was sufficient evidence of the progress of the Romford Gas Company; and if this progress continued at the same rate, it would not be long before the firm would have the pleasure of building another holder for the Company.

Gas at the Printers' Exhibition.

The above exhibition at the Royal Agricultural Hall, Islington, is one of the best of its kind that has been held in connection with the printing trade, and is of exceptional interest to the gas industry, if only for the fact that no solid fuel whatever is used in connection with any of the furnaces that are being displayed. Gas has been applied in every case, and a great deal of interest has been created in this connection. The surface combustion plant supplied by British Furnaces, Ltd., of Chesterfield, is shown as standard equipment on the stands of the largest firms represented at the exhibition. An illustrated description of the applications of gas to the printing trade, as demonstrated at the exhibition, will appear in the "Journal" next week.

Main Surveying by Air.—The "American Gas Association Monthly" reproduces a photograph showing the method employed by the Louisville Gas and Electric Company for locating pipeline rights-of-way by means of aeroplane pictures. In this type of work precise surveying is not essential; and the air photographs indicate the exact location, in approximately correct scale, of everything on the surface of the ground—such as streams, houses, and fences. Photographic maps may also be used to obtain contours, by simply running a base line along the object to be surveyed.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Gas Engineers as Directors.

Sir,—Dr. Carpenter, in his speech last year at the luncheon giv by the President of the Institution of Gas Engineers, raised a ve interesting and important point. He asked where had we men the gas industry to-day to follow in the steps of the great men the last generation—Sir George Livesey, Sir Corbet Woodall, M Charles Hunt, Mr. Harry Jones, &c. To-day, more than ever, t gas industry requires men of this calibre, not only to assist its pr gress, but also to protect its interests in face of Government su vention to a younger, and in many ways a rival, industry.

The honoured names mentioned by him were all borne by tho who were engineers in the first place. I would submit that we ha in our industry to-day men of equal technical ability; it would sad to think we had not those who have the necessary personali and character latent in them. I believe it is only opportunity th is lacking.

Our technical men are kept far too much to executive wor Managerial and directorial responsibilities develop personality, i crease confidence, and make character. Many gas companies ha on their staffs engineers who have proved their true worth as exec tive officers, and who have made their companies' interests th life work. If in such cases these men were appointed to the Boa of Directors while still retaining their executive duties, I am su the companies would benefit, and the gas industry would be strengt ened, by having at their call men of high technical skill, and fu used to directorial responsibilities.

We need our fullest strength, organized on the basis of the i dustry as a whole, and co-ordinated with one ideal before us—t good of the nation and the good of the gas industry.

Arthur Duckham,

52, *Grosvenor Gardens, London, S.W.* 1,
May 25, 1925.

Mr. Milne Watson and Government Electricity Development Schemes.

Sir,—Your readers will peruse with keen interest the able addr that our President, Mr. D. Milne Watson, delivered at the annu meeting of the Society on the 20th inst.

The subject with which he dealt is of such vital importance to branches of the gas industry that your readers may be interested learn that we are enlarging somewhat on the suggestion of our n President (the Rt. Hon. Sir Alfred Mond) by circulating a repr of the address to every Member of Parliament, thereby giving them opportunity of realizing *facts* which otherwise perhaps might come to their notice.

B. B. Waller,
Chairman of the Council of the Society of Brit Gas Industries.

56, *Victoria Street, Westminster, London, S.W.* 1,
May 25, 1925.

Low C.V. Gas and the Unaccounted-for Gas.

Sir,—As Mr. Keillor has so well pointed out, the distribution low C.V. has nothing whatever to do with unaccounted-for g Further, he urges that the Technical Press would be helpful to t industry if they were much more aggressive in their criticism such ridiculous statements. I wish heartily to endorse Mr. Keillo remarks.

I should also like to direct attention to Mr. West's most rec utterance on the subject: "I still think, however, that before a lo grade gas can be distributed successfully all over the country, mu preliminary work in the way of improving, purifying, and cleanin out distribution systems will require to be undertaken in many cas unless someone comes along with a new type of meter."

Such a statement means nothing short of this—that in Mr. We opinion the gas industry should regulate the quality of gas it suppl to suit the measure used to register consumption. Apply such reas ing to any other trade. Do the scales or measures by which go are sold limit the quality or cheapness of such goods?

Geo. Helps

Nuneaton Gas Company.
May 21, 1925.

A Useful Sport.—Ratting by Motor Car.

Sir,—The danger lurking in the fumes from motor cars when exhaust is allowed to escape within the confines of the garage w pointed out in the "Journal" for May 6, p. 362.

This danger can best be exemplified to the popular mind by turni to the credit account the asphyxiating qualities possessed by these haust fumes. The fumes are particularly heavy, and if, when in rat infested area, a hose be attached to the exhaust and led to a hole, the gases will soon permeate the rat warren, and displace lighter air, thereby asphyxiating the young rats and forcing the rats to the surface, where a good dog would have the time of life. Considering the vast numbers of motor cars held by you sportsmen, the damage done by the hordes of rats left us as an aft math of war should soon be reduced to negligible proportions, w advantage to human health, and added peace of mind.

Ad Rem

At a meeting of the Rhyl Urban Council last week it was sta that the Gas Department showed a profit for the past year of £218 after paying loan charges of £1514.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

Statutory Gas Companies (Electricity Supply Powers) Bill: Brought from the Commons, and read the first time.

Forfar Gas Order Confirmation Bill: Returned from the Commons, agreed to.

Oldham Corporation Bill: Reported, with amendments.

Uckfield Gas and Electricity Bill: Read the third time, passed, and sent to the Commons.

Blackpool Improvement Bill: Reported from the Select Committee, with amendments.

Gas Regulation Act.

In the House of Lords, on the 19th inst., the Earl of Clarendon (on behalf of Viscount Peel) moved that the draft Special Orders relating to the Altrincham Gas Company and the Stockton-on-Tees Corporation proposed to be made by the Board of Trade be approved; and this was agreed to.

HOUSE OF COMMONS.

Progress of Bills.

Forfar Gas Order Confirmation Bill: Read the third time, and passed, without amendment.

Kilmarnock Gas and Water Provisional Order Bill: Committed, read, and discharged; considered, read the third time, and passed.

Horley District Gas Company (Electricity Supply) Bill: Reported (preamble not proved).

Uckfield Gas and Electricity Bill: Read the first time, and referred to the Examiners.

South Metropolitan Gas Bill: As amended, considered; to be read the third time.

The draft of a Special Order proposed to be made by the Board of Trade under section 10, on the application of the British Gas Light Company, with respect to the Trowbridge undertaking, was presented to both Houses.

Gas Companies and Electricity Supply.

Mr. LOOKER, on the 18th inst., asked the Minister of Transport whether he would give an undertaking that, under the scheme of general electrification contemplated by the Government, the rights and undertakings of existing gas companies would be duly protected.

Colonel ASHLEY, in reply, said the Government's proposals in this matter had not yet been formulated. At present, therefore, it was impossible to say whether any questions would arise under the last part of the question. The Government had got to consider the proposals which were now being sent up to them.

HORLEY DISTRICT GAS COMPANY (ELECTRICITY SUPPLY) BILL.

House of Commons Committee, Monday, May 18.

(*Before Major* MALONE (Chairman), *Mr.* SAVERY, *Mr.* C. W. CROOK, *and Sir* HENRY JACKSON.)

The purpose of the Bill was to empower the Horley District Gas Company to supply electricity, jointly with gas. There was opposition by the Horley and District Electricity Supply Company, Ltd., to whom the Electricity Commissioners have already granted a Special Order for the purpose of supplying electricity in Horley, which Order is now awaiting confirmation by the Minister of Transport.

The Gas Company were represented by Sir HARRY COURTHOPE-MUNROE, K.C., and Mr. JACQUES ABADY; and the Electricity Company by Mr. W. CRAIG HENDERSON, K.C., and Mr. F. J. WROTTESLEY.

The Bill had already been passed by the House of Lords, where an obligation was put upon the Gas Company to supply electricity within the compulsory area within twelve months after Royal Assent had been given to the Bill. (The proceedings before a Committee of that House, presided over by the Earl of Clarendon, were reported in the "JOURNAL" for March 25, p. 750; April 1, p. 63; and April 8, p. 128.)

The story which was presented by Sir HARRY COURTHOPE-MUNROE, who opened the Bill, was the same as that put before the House of Lords Committee on the previous occasion, and the opposition by the Electricity Company was the same. Briefly, the position, as stated, was that the Gas Company decided, in 1922, when Mr. H. J. Randall (Engineer and Manager of the Yorktown and Blackwater Gas and Electricity Company) became a Director of the Horley Gas Company, to apply for powers to supply electricity. A statutory gas company, however, can only obtain such powers by the promotion of a Bill in Parliament; and, in view of the heavy expense involved thereby, and the fact that Mr. R. G. Clarry, (M.P. for Newport) was to present a Bill to Parliament which would enable statutory gas companies to apply to the Electricity Commissioners for an Order giving electricity powers, thus placing them in the same position as any other company, the Horley Gas Company decided to await the passing of Mr. Clarry's Bill. The matter dragged on until 1924, when it was considered that, owing to the state of Parliamentary business, the passage of Mr. Clarry's Bill was uncertain; and the Gas Company promoted the present Bill. Meanwhile, the residents at Horley had formed a Company for the purpose of supplying electricity, and, though the Gas Company had informed them of the steps they had taken, the Electricity Company applied to the Electricity Commissioners, and obtained an Order empowering them to supply electricity. This Order is awaiting confirmation by the Minister of Transport; and, as the Gas Company have lodged an objection, an inquiry has to be held before confirmation is given. The Gas Company claim that, being an established Company, they are in a better position to supply electricity cheaply, inasmuch as they could raise capital more cheaply, and could employ their present Directors, staff, and workmen in the two undertakings, so spreading overhead charges over the two undertakings. They also claim that they had the matter of electricity supply under consideration before the gentlemen who had formed the Electricity Company; but the latter claim that the Gas Company's activity is the result of the formation of the Electricity Company, and that the Gas Company wish to obtain electricity powers in order to avoid active competition with gas.

COUNSEL pointed out to the Committee that Parliament had, on 23 occasions, granted power to gas companies to supply electricity, and emphasized that a cardinal feature of the Horley Gas Company's scheme was that the waste heat arising from the process of gas manufacture was to be used for generating electricity. It was estimated that, in the first year, three-quarters of the electricity produced would be generated by steam raised from this waste heat, and that in the second year two-thirds would be so generated, so that only one-quarter of the electricity in the first year, and one-third in the second year, would have to be generated by fuel-consuming engines.

Mr. *H. J. Randall* (Director of the Horley District Gas Company, and Engineer and Manager of the Yorktown and Blackwater Gas and Electricity Company), said that at the first meeting of the Horley Company which he had attended as a Director he had brought forward the question of electricity supply, because he considered that the district would be bound to have a supply sooner or later, and the time was opportune for the Gas Company to provide it. The Directors had considered the matter, and he had dealt with the engineering aspects. The obvious thing to do was to obtain a bulk supply, if possible; but, owing to the difficulty of obtaining a suitable supply, the Company decided to generate electricity themselves. He confirmed Counsel's statement as to the steps which had been taken. He considered the Horley Gas Company were in a better position to supply electricity than was a new company dependent on electricity revenue alone. A suggestion had been made by the petitioners that dividends payable on certain of the stock would be subject to a sliding-scale dependent on the price of gas, and not on the price of electricity, and as a result of the proposals of the Bill it would be in the interests of the Gas Company to reduce the price of gas in order to earn the right to pay a higher dividend on the capital to be used for the electricity undertaking, and to earn the money required for paying that higher dividend by keeping-up the price charged for electricity. In reply to this, Mr. Randall pointed out that the gas and electricity capital would be kept separate, and that the accounts had to be submitted to auditors appointed by the Electricity Commissioners, and if it were found that the Company were doing such a thing, they would be quickly brought to book. But, from the practical point of view, after £15,000 to £20,000 had been spent on electricity mains, surely it would be suicidal to increase the price of electricity to the maximum, and prejudice the possibility of increasing the demand for electricity so that the gas would benefit. Even if that were done, the increased remuneration resulting from increasing the price of electricity would be so small as to be practically negligible in affecting the dividend. Witness then referred to the supply of electricity and gas by the Yorktown and Blackwater Company, and gave figures to show that the electricity and gas undertakings had both developed rapidly side by side. The development of the electricity undertaking there had stimulated the sale of gas as well.

Mr. CRAIG HENDERSON, in the course of his cross-examination, put a number of questions, in which he suggested that the surplus heat generated in the gas manufacturing process was used for generating steam for auxiliary plant in the gas-works themselves in up-to-date works. Therefore, if it were used for generating electricity, the gas-works must go without some of these modern appliances.

Witness replied that some of the big works were using waste heat in this way, but the question was a new one; and, inasmuch as waste solid fuel—which fuel could not be sold—was used for generating steam in the Horley Gas-Works, the waste heat which it was now proposed to use for generating electricity would be wasted unless it was so used.

The Committee adjourned.

Tuesday, May 19.

Mr. *William Cash* (of Messrs. Cash, Stone, & Co., Chartered Accountants, Past-President of the Institute of Chartered Accountants, and Chairman of a number of gas and other public utility companies) was then called to give his expert views as to the suggestion that the Gas Company, if given electricity supply powers, might keep up the price of electricity, so as to reduce the price of gas and enable higher dividends to be paid under the sliding-scale. He did not argue with the statement as such, because where there was a sliding-scale, of course, a company's interests lay in reducing the price of gas and so increasing the dividend; but it only applied so far as it was not checked by commercial considerations. The Horley Gas Company, for instance, were to-day charging a price for gas which would enable them to pay a higher dividend than was actually being paid. He himself was Chairman of the Bournemouth Gas and Water Company, where a sliding-scale operated with regard to gas supply; and it might be said that that Company charged a higher price than was necessary for water, in order that a higher dividend might be paid by reducing the price of gas. But this was not so. The water and the gas charges were regulated by legislation, and the Company were not paying anything like the dividend they might pay. He referred to other companies where two commodities were being supplied, one of which was the Tottenham District Light, Heat, and Power Company, which supplied gas over a large area, and in one district—Wood Green—both gas and electricity. The progress made in regard to both gas and electricity sales in Wood Green had been rapid; and, in spite of the supply of the two commodities being in the same hands, electricity development had not been stifled in any way. Again, at Bognor, where gas and electricity were in the same

hands, there had been a simultaneous decrease in the price of each, and a progressive increase in sales. It was the commercial aspect which really applied—a company which had embarked capital in their undertaking would, in their own interests, make the thing a success if possible. To do this, they would keep prices down, and in the case of both commodities a decrease in price was almost invariably followed by an increase in sales. Dealing with the capital of the Horley Company, witness said that the total amount which could be paid in extra dividends as the result of a reduction in the price of gas of 1d. per 1000 c.ft. was £82, and it was not likely that the Company, for the sake of another £82 a year, would embark on substantial capital expenditure in connection with electricity. There were other companies supplying both commodities, and he had never heard any suggestion of unfairness.

Asked by Mr. Craig Henderson, in cross-examination, to give information as to the results obtained where there were two competing concerns supplying gas and electricity, Mr. Cash referred to the Croydon Gas Company, which was competing with the Corporation electricity undertaking. Both concerns were growing rapidly. Asked whether the enormous strides made in the development of the gas industry were not due to the competition offered by the introduction of electricity, he admitted that this was a factor. It was then suggested by Counsel that, though the Horley Gas Company had been supplying gas in Horley since 1886, yet local residents had now subscribed £10,400 in order to set up a competitor to supply electricity; and he asked whether this did not suggest that the community would be better supplied if the competitor were allowed to go on. Mr. Cash replied that it did not necessarily follow, and that the combination of the two undertakings would result in advantages to the community.

Sir Harry Courthope-Munroe said he was willing that, if the Committee could devise any safeguard against the tendency suggested by the petitioners, it should be inserted in the Bill.

Mr. A. Hugh Seabrook (of Sir Charles Bright & Partners, Electrical Engineers, and late General Manager and Engineer to the West Ham and St. Marylebone Corporation electricity undertakings) said he had been advising the Horley Gas Company with regard to the scheme, which was on the same lines as other schemes which had been sanctioned by Parliament, except that it was proposed to generate a portion of the electrical energy supplied by means of surplus heat from the gas manufacturing process; there being sufficient surplus heat to produce about 900 lbs. of steam per hour. In the first year of electricity supply, three-quarters of the electricity required would be generated by this means, and in the second year two-thirds of it; the saving in the first year by this means being £219, which was substantial in a small undertaking. Generating costs in the first year he estimated at £373, £300 of which represented wages and repairs and maintenance of plant, and £73 cost of fuel (gas or oil) required to drive the engines which would produce that portion of the electricity not generated by utilization of waste heat. Since the Bill was promoted, the Gas Company had promised to give a bulk supply to the Sussex Electricity Supply Company, Ltd., for the purpose of supplying Crawley, which adjoined the proposed electricity supply area of the Gas Company, and was within the existing gas limits. It would be a great advantage to have a big customer of this sort. Witness handed-in tables showing the estimated results of the working of the undertaking in the first two years, which were exactly the same as those given when the Bill was in the House of Lords.

It was pointed out by Mr. Craig Henderson, in cross-examination, that, though the accounts of the two undertakings were to be kept distinct, the gas undertaking was handing-over fuel to the electricity undertaking and charging nothing for it; and he suggested that that was why Mr. Seabrook was able to show a profit from the first year's working of the electricity undertaking. [The net profit estimated for the first year was £532.] Witness replied that the surplus heat would otherwise be wasted. Questions were then put with regard to stand-by plant, it being stated by Counsel that if one generating set, of 50 kw. capacity, broke-down, the maximum output would be 30 kw. to meet a maximum load of 50 kw. Mr. Seabrook agreed, providing the 50-kw. set broke-down completely; but a breakdown might not necessarily involve the stoppage of the complete set. In answer to further questions, in which it was suggested that there was no stand-by plant provided, witness disputed this, saying that the scheme compared with similar schemes in this respect; he had provided what experience had proved to be sufficient, and there was sufficient stand-by plant provided except for about 100 hours or so throughout the whole year, when the demand was at its peak.

With regard to the generating station, Counsel was concerned because this was to be placed in the centre of the gas-works. If the present Bill were passed, the consent of the Electricity Commissioners would have to be obtained before the generating station could be erected, and they would have to take into consideration the fact that, whereas the Local Authority had statutory power to purchase the electricity undertaking, they had no such power to purchase the gas undertaking. Therefore, by placing the electricity generating station in the centre of the gas-works, surrounded on all sides by buildings, the local authority would be denuded of their statutory right to purchase it. Witness replied that in a previous case, where similar conditions obtained, it was provided that, if the local authority exercised their right to purchase the electricity undertaking, they could also purchase the gas undertaking by agreement. Counsel retorted that the local authority might not wish to do this, and added that a movement was on foot to make Horley an urban district, instead of part of a rural district as at present. Mr. Seabrook remarked that even if the Local Authority purchased the undertaking, they would not be able to supply electricity cheaper than the Gas Company could.

Mr. *A. E. Broadberry* (Director of the Tottenham District Light, Heat, and Power Company) gave evidence as to the success which had attended the supply of both gas and electricity in Wood Green, and stated figures to show that there had been rapid progress in that area in the development of both. Applying his experience to the conditions in Horley, it was fair to assume that the supply of electricity by the Gas Company would lead to equally good results. Further, the Horley Gas Company had an advantage which the Tottenham Company lacked at Wood Green—namely, the utilization of surplus heat from the gas-works for the generating of electricity. To show that the practice of joint gas and electricity supply was widely adopted in the United States, witness had procured a list of 384 American concerns which were supplying both commodities.

Mr. Craig Henderson, in cross-examination, suggested that the conditions at Wood Green and Horley were not comparable, because the gas-works and the electricity generating station for the former were a long way apart. To his suggestion that other companies were supplying electricity cheaper than were the Tottenham Company, Mr. Broadberry retorted that he must have picked out special cases, and himself referred to instances in which electricity companies were charging higher rates than the Tottenham Company.

Mr. *George Baker* (a resident of Horley) spoke of the desirability of a supply of electricity in Horley, and was of opinion that the residents stood a better chance of getting a supply from an established company than from a new company. He did not believe the gas consumers of Horley, as a body, had any complaint to make against the Gas Company.

Mr. *D. Napier-Whittingham* (Managing Director of the Sussex Electricity Supply Company, Ltd.) corroborated the statement that his Company wished to take a bulk supply from the Gas Company for the supply of Crawley. They would be unwilling, however, to arrange for a bulk supply from the Electricity Company, if the present Bill were rejected. Replying to Mr. Craig Henderson, in cross-examination, he admitted that, if he were satisfied that the new Electricity Company were sound enough to be able to give his Company a bulk supply of a sufficient quantity, over and above that required for the supply of Horley, his Company would rather take that bulk supply than generate electricity themselves.

Sir Harry Courthope-Munroe, in order to meet the objection by the petitioners that the price of electricity might be increased in order to reduce the price of gas and allow larger dividends, offered to insert a provision for the revision of the maximum prices for electricity by the Electricity Commissioners, in accordance with the provisions in the schedule of the Electricity (Supply) Act, 1922. The Gas Company, however, were still of the opinion that it was not really wanted.

This closed the case for the Gas Company.

Mr. W. Craig Henderson, in his address on behalf of the Electricity Company, impressed upon the Committee that it was the direct result of the possibility of a competitor coming into the field that the Gas Company had become seized with an affection for electricity supply. He also pointed out that never in the history of gas and electricity legislation had Parliament given a gas company electricity powers in competition with an electricity company who applied for powers at the same time. Dealing with the point made by the Gas Company, that when the Electricity Commissioners had granted the Electricity Company's Order the Gas Company had not been heard, he said that the Commissioners had only one scheme before them which they could consider. As to the procedure which should have been followed subsequently, he said that when confirmation of an Order was objected to in the House of Commons, the procedure laid down by the Speaker was that the matter should be referred to a Committee. The proper procedure for the Gas Company to have adopted would have been to have let the Electricity Company's Order come into the House, and to have got somebody to put up a motion against confirmation. Then the Order and the Gas Company's Bill would have come before a Committee as competing schemes. Instead of this, the Gas Company had lodged a memorial with the Ministry of Transport, objecting to confirmation of the Order, which rendered it necessary for the Minister to hold an inquiry, and the Electricity Company's scheme was held-up outside the House until the present Bill was heard. This procedure had put the Electricity Company at a disadvantage. In Horley the Gas Company had been selling gas without any competition, but when a competitor came along they wanted that competitor under their own control. He submitted most strongly and most confidently that it would not be in the interests of any public consumer in Horley that the electricity supply should be taken out of the hands of the local residents (who were so keenly interested in it as to put up £10,400 out of their own pockets), in order to give that power to supply to the Gas Company, who were only taking it up because they felt at last compelled to do so. At this point, Mr. Craig Henderson introduced a new aspect from which to view the whole question. It had been stated by both parties that it would have been preferable to obtain a bulk supply for distribution in Horley, if such a supply could be obtained on suitable terms; but that, owing to the difficulty of securing such a supply, each had decided to generate locally. It was now announced by Counsel that the Horley Electricity Company had made arrangements for a bulk supply from the County of London Electric Supply Company, whose super power station was at Barking, and whose mains stretched almost to the borders of Horley. The price was one which the Horley Electricity Company were willing to pay; and the arrangement would not only dispense with the proposal to erect a small generating station at Horley, but would bring to Horley an unlimited supply of power, which could be distributed at a reasonable price. It would carry out the policy which the Electricity (Supply) Act of 1919 had in view—namely, the grouping into centres of electricity generation, and the dispensation of the operation of small generating stations. As to the point raised by the Electricity Company, that, where gas and electricity were supplied by one company, any profits from electricity affected the price of gas, he said that Mr. Cash, in his evidence, did not gainsay it, but had said that it was checked by commercial considerations. But what kind of commercial considerations would one get from a gas company such as that at Horley, one of whose Directors had said in evidence that the amount of electricity he would sell in Horley would be small as compared with the amount of gas, and would not be sufficient to affect his dividends? Was that the kind of electricity development the Committee wanted in Horley? The Electricity Company wanted to do better than that, and wanted to be allowed the chance. They

uld be good competitors with the Gas Company, and would make m do better as a gas supply authority. This sort of competition s the life of industry. In this particular case there was the first nstration of the proposed exclusion of a local electricity supply com ny, armed with a Special Order, as against a gas company which d never done anything much in the way of gas supply, let alone ctricity supply.

Wednesday, May 20.

Mr. CRAIG HENDERSON, dealing with Mr. Seabrook's estimates of working of the electricity undertaking by the Gas Company, ited that they were not worth the paper they were written on, be use they were based on the supply to Horley alone, whereas it had w been stated that it was proposed to give a bulk supply to Crawley. that were so, then the plant required would be quite different from it required if only Horley had been supplied.

Mr. *C. R. St. John* (Consulting Engineer advising the Electricity mpany) gave evidence as to the scheme of the Electricity Company supplying Horley, and referred to the delay which had resulted m his efforts to obtain a bulk supply in the first place, which d not materialize. He had then decided to erect a local generating tion, but would not now proceed with this, in view of the offer by e County of London Electric Supply Company to supply in bulk. e terms for this bulk supply were to be £6 per kilowatt per num, *plus* a running charge of 0·75d. per unit. Therefore, the bles he handed in to the Committee, to show the results of the orking of the undertaking, differed from those submitted in the ouse of Lords, inasmuch as they were based on obtaining a bulk pply, and showed that in the first year he hoped to meet all charges thout making a profit; in the second year he expected a surplus of 400; and in the third year a surplus of £1000.

Sir HARRY COURTHOPE-MUNROE, cross-examining, pointed out at, since the Electricity Company had commenced preparing their hemes, four different sets of figures had been produced. He also certained from witness that no contract had yet been made by the orley Electricity Company with the County of London Company for bulk supply, and suggested that the terms of the contract were ill in the air.

Witness replied, however, that they were in an acceptable form.

In the course of further questions, Sir Harry obtained from witness e admission that there were no powers existing which would enable e main to be laid to carry the bulk supply from the termination of e County of London's Company existing mains to the borders of orley, and pointed out that nothing was contained in witness's gures to cover the cost of obtaining such powers. He suggested that the present Bill were thrown out, and the Electricity Company ught powers to carry their main over other people's territory, as ey would have to do, some of the parish councils might raise objec on—it was proposed to provide an overhead wire, which system was uitful of opposition—and therefore, the position of the Electricity ompany was not a safe one. Witness replied that he did not antici ate difficulty in this connection, and considered the present scheme a fer one than his previous plan.

Mr. *F. C. M'Quown* (Manager and Secretary of the County of ondon Electric Supply Company) corroborated the evidence that his ompany were willing to give a bulk supply to the Horley Electricity ompany if the latter Company obtained powers to supply in Horley.

Sir HARRY COURTHOPE-MUNROE pressed witness as to the posi on of the County of London Company's mains at the present time, id ascertained that they terminated at a point which was 9 miles om Horley as the crow flies, and 11 miles by road. It was ex ained that the County of London Company hoped to obtain powers supply in part of the area between their existing area and Horley, id they would then provide four miles of the bulk supply main. he Horley Electricity Company would either obtain powers to supply the remainder of the area between the two companies, or get a rayleave, and provide the other 5 miles of main. There were no owers existing at the moment, and Counsel pointed out that, if here was opposition, it would take time and cost money to get these owers.

Witness said that his Company would lay their part of the main five or six months after obtaining the necessary Order. Re examined, he said it was part of the policy of his Company to afford ulk supplies to companies who were distributing electricity only.

Sir *Harry Haward* (one of the Electricity Commissioners), ques oned as to the complaint of the Gas Company that they were not eard when the Commissioners considered the Electricity Company's rder, said that the Commissioners could not have considered the as Company's scheme, because it was not before them. In some ases the Commissioners were asked specifically to hold a local in uiry, but no such request had been made in this case. (The evidence iven is to the effect that the Commissioners were informed, before he Electricity Company's Order was granted, that the Gas Company ntended to apply to Parliament for powers.) The general view of he Commissioners on the question of entrusting gas companies with lectricity supply powers was that there might be cases where it was ight and proper that the supply of electricity should be entrusted to a as company, because this might be the only means by which a dis rict could get a supply. Therefore, they did not consider that the roposal to entrust gas companies with these powers should be pposed on principle. They recognized, however, that on general rounds it was preferable that the supply of electricity should be in he hands of a body whose primary and sole duty was to supply elec ricity, where there was such a body able and willing to undertake it. t the same time, it must not be supposed that in every case the Com aissioners would think it should be entrusted to an electricity com any, because there might be cases in which a gas company could how an overwhelming advantage over an electricity company.

Mr. *R. L. Norris* (Chairman of the Horley Electricity Company) aid that that Company could have raised more than the £10,400 of apital already raised, but for the rumours existing with regard to he opposition of the Gas Company to their scheme. He was not ltogether satisfied with the Gas Company as a gas company, and considered that the Electricity Company would give a better supply of electricity than would the Gas Company.

Mr. *A. C. Cramb* (Chief Engineer and Manager, Croydon Corporation Electricity Department) expressed himself in favour of competition between gas and electricity undertakings, because it was a good thing for both. It would be unfortunate for the residents of Horley, in his view, if the supply of electricity and gas were under the same control. He gave figures showing the growth of the gas and electricity undertakings at Croydon, where there was active competition.

Sir HARRY COURTHOPE-MUNROE, summing up for the Gas Company, asked the Committee to consider the two schemes, as was done by the House of Lords Committee, and suggested that this was a case where Sir Harry Haward's remark as to a gas company showing an overwhelming advantage over an electricity company exactly fitted. The Committee, he said, were now asked by the Electricity Company to consider their fourth edition of figures; and the scheme as now put forward had not been considered by the Electricity Commissioners. This was an extraordinary state of things. If the Committee approved of the scheme, there was not a rag of certainty about it. The existing mains of the Company who were to give the bulk supply were miles away from Horley; and before they could get to work they had to get two, and possibly three, Orders. This meant delay; and if there were opposition when they applied for their Orders, there would be still more delay. After the Orders were obtained, they had something like eighteen months of work in front of them; and he considered that it would be three years before Horley had the least chance of getting a supply. Therefore, it seemed ridiculous to ask the Committee to throw out the Gas Company's Bill. If it were passed, there would be an obligation upon the Gas Company to supply electricity within one year. It had been suggested that the Gas Company would juggle with the accounts, but he was content to adopt any safeguard in that connection which the Committee could devise. Again, the Gas Company proposed to supply a larger area than did the Electricity Company. So strongly did he feel that the Gas Company were able to meet any competition that he suggested that they should be given their Bill, and the Electricity Company's scheme could be confirmed by the Minister of Transport, if he thought fit, and then there would be centred in Horley the most intense cut-throat competition there could be.

The Committee conferred in private, and their decision was that the Bill be rejected.

OLDHAM CORPORATION BILL.

This Bill was considered by the Unopposed Committee of the House of Lords, presided over by the Lord CHAIRMAN (the Earl of Donoughmore) on Tuesday, May 19, and ordered to be reported for third reading.

There are some clauses of a general nature relating to the Oldham gas undertaking (referred to in the "JOURNAL" for Jan. 21, p. 143), and there has been no substantial alteration to these.

Evesham Gas Undertaking.—The annual report and statement of accounts have just been issued in connection with the gas undertaking of the Evesham Town Council. The increase in the make of gas was 1¾ million c.ft. The revenue account showed the total expenditure to have been £26,609, and the total receipts amounted to £28,801, leaving a balance (gross profit) of £2192. The amount received from the sale of gas was £18,561, against £17,985 last year. The capital expenditure, after deducting depreciation, stood at 36,549. Stocks on hand were valued at £1441, and the amounts due from sundry debtors £5324. On the other side, the amount of loan outstanding was £35. The next payment would wipe out the loan altogether. Alderman Fisher, the Chairman of the Committee, in moving the adoption of the accounts, remarked that, in view of the reduction in the price charged for gas, and the depression in trade generally, he thought they would agree that they had had a satisfactory year's trading.

LEGAL INTELLIGENCE.

ELECTRIC LIGHT AT BARWELL.

The question of substituting electric light for gas in Barwell, Leicester, came before the Divisional Court on Thursday, May 21, before Mr. Justice SALTER and Mr. Justice GREER.

The matter was raised on an *ex parte* motion by Mr. J. B. MELVILLE, who said he had to move, on behalf of Mr. Thomas Powers, for a rule directed to Mr. Wm. Freer, Chairman of the Barwell Parish Council, calling on him to show cause why a writ of *mandamus* should not issue, directing him to hold a poll of the electors of the parish of Barwell. There was an affidavit by Mr. Powers in support of the motion. In this Mr. Powers said he was a farmer, and Chairman of the Earl Shilton Gas Light and Coke Company. He was the owner of property in the parish of Barwell, and a local government elector on the register of voters in force in the parish, which was a rural parish with a population of 3008 or thereabouts, with an assessable value of about £12,357. He had been a member of the Barwell Parish Council for the last fifteen years, and was also a member of the Leicestershire County Council. A printed notice of a parish meeting purporting to be issued by Mr. Wm. Freer, the Chairman, was published in the parish, for a special parish meeting to be held on May 4. The meeting was convened, said Counsel, with respect to a proposal to raise a loan of some £900 for the purpose of establishing electric lighting in the parish. He (said deponent) attended the meeting, and voted against the resolution. Seventeen voted in favour of it, 14 voted against it, and 20 did not vote at all. The resolution was then declared carried, on a show of hands. He (deponent) demanded a poll on the resolution; but the Chairman refused to take one. On May 8 he instructed his solicitors to write to Mr. Freer informing him that unless notice of a poll was issued within seven days, in accordance with his request, application would be made to the High Court for a *mandamus* to compel him to carry out his duties according to law. Mr. Freer's reply to that letter, said Counsel, was addressed to Mr. Powers' solicitors. In it he said: "Your letter did not come as a surprise, knowing your client's love for the law and his many threats when crossed or baulked in any matter invoking its aid. I may say, as far as I am concerned, I do not accede to your client's demand for a poll. After giving the matter further consideration, I see no reason to alter my decision. According to my lay mind, I am justified in the course I have taken, and you may take what course you or your clients may desire." As a result, this application was made, added Mr. Melville, and the question involved was whether electric light should be substituted for gas, which had been previously supplied by the Earl Shilton Gas Company to this parish under the Local Government Act of 1894.

In the result, the Court granted a rule, to be returnable for argument one day early next term.

MISCELLANEOUS NEWS.

GAS REGULATION ACT APPLICATIONS.

The following notices have appeared in the "London Gazette" regarding applications to the Board of Trade under the Act.

SPECIAL ORDERS.

Langley Mill and Heanor Gas Light and Coke Company, Ltd.

The Company intend to apply for an Order under section 10, authorizing them to extend the limits of supply, to raise new capital, and to make provision for the more efficient conduct of the undertaking.

Hornsey Gas Company.

The Company intend to apply for an Order to authorize them to convert existing stock and create new stock, to define dividend rights, &c., to make provision as to borrowing, and for other purposes.

Oswaldtwistle Urban District Council.

The Council are applying for an Order to enable them to purchase additional lands, to make regulations regarding the laying of pipes, to charge on a thermal basis, to borrow money, and to fix the maximum price of gas at 1s. 3d. per therm.

Low-Temperature Carbonisation.—A circular has been issued by Low-Temperature Carbonisation stating the reasons for the creation of £500,000 of new debenture stock. This was agreed to at a meeting of stockholders held on May 5. It is an income charge issue, bearing 8 p.ct. interest cumulative, and the right to participate in profits for a further 4 p.ct. The amount to be issued at once is £300,000. It is offered at 95. The remaining £200,000 is held in reserve for exchange for the existing 6 p.ct. first mortgage debenture stock, or alternatively for issue in connection with the acquisition and completion of further contracts for the erection of low-temperature plants in the principal industrial centres.

Houghton-le-Spring Gas Company.—At the annual meeting of the Houghton-le-Spring Gas Company, of Durham, a satisfactory report was submitted; but the Chairman (Mr. W. A. Surridge) said he was afraid the outlook in regard to residuals was still unfavourable. They had already reduced the price of gas, and proposed to make another reduction shortly. A new holder was almost completed, and would be put into use shortly. They had entered into an agreement to take a supply of coke-oven gas from adjacent collieries, and expected it would enable them further to reduce the price of gas. The Board proposed to make an issue of new capital. A dividend of 7 p.ct. on the ordinary shares, compared with 6 p.ct. last year, was agreed to.

SAFEGUARDING OF INDUSTRIES ACT.

Gas Mantles.

The Inquiry into the application of the Incandescent Mantle Manufacturers' Association for the imposition of a duty on imported g mantles, under the Safeguarding of Industries Regulations, w opened at the Board of Trade Offices on Monday, May 18. The Co mittee consists of Sir FREDERICK MILLS, Bart., Sir JOHN BARRA Bart., and Mr. J. ARTHUR AITON.

The Incandescent Mantle Manufacturers' Association were rep sented by Mr. J. P. H. Soper (Managing Director, Monarch Mantl Ltd.). There was opposition to the imposition of a duty by a gro of importers of foreign mantles, members of the London Chamb of Commerce.

Mr. *Soper*, before giving evidence, dealt with the instructions Committees set up to inquire into applications under the Safeguardir of Industries Regulations, in their application to this particular i quiry, and showed how these instructions had been interpreted by t Association. The first point upon which it was the duty of the Co mittee to report was whether the industry was one of substantial in portance, from the point of view of the employment it afforded. I claimed that the mantle industry was of importance by reason of t nature of the goods it produced. Gas was probably the princip source of artificial light in the country at the present time. The g mantle was the key to modern gas lighting and to modern gas pr duction.

The next point to be considered by the Committee was whethe foreign goods of the class or description to which the application r lated were being imported into, and retained for consumption in, t United Kingdom in "abnormal" quantities. He thought it cou be said that practically the whole of the foreign mantles that can to this country were retained for home consumption. Foreign mantl only entered into the export trade of this country to a negligib degree; British manufacturers held what export trade there was, ar they were enabled to do this by reason of the preference which w granted to British-made goods by the Dominions. The important wo in this part of the instructions to the Committee was "abnormal. He believed it had been suggested as a general test that the relati home and foreign trade in the goods, in respect of which an impo duty was sought, before the war should be regarded as normal. I claimed, however, that pre-war conditions so far as gas mantles this country were concerned were not conditions of fair competitio The trade in gas mantles was then dominated by Germany, who h secured the control of the monazite sands. He suggested that t standard for the normal quantity of sales of home-manufactur mantles should be determined by reference to the importance of t article. If the Committee could be satisfied that the gas mantle w an article of national importance, then the home manufacturers shou have high percentage of the home trade. If it were found that t home manufacturers were in jeopardy through the volume of import and were only retaining a portion of their business by selling mantl at unremunerative prices, then he submitted that imported mantl were being retained in this country for home consumption in "abno mal" quantities. The percentage of sales held by British manufa turers was steadily falling, and during the last three months it h declined to an alarming extent.

The next question for the Committee was whether the foreign goo so imported were being sold or offered for sale in the United Kin dom at prices below those at which similar goods could be profitab manufactured or produced in the United Kingdom. He submitte that the Committee had to determine total competition, and not isol ted instances. To the average prices shown by the Customs retur there should be added a small amount in respect of the duty levied the thorium contents, and allowance must be made for the cost clearance from the docks to customers' warehouses. The addition respect of these two items was about 1s. or 1s. 6d. per gross.

The Committee had also to decide whether such exceptional compe tion came largely from countries where the conditions were so di ferent from those in this country as to render the competition unfai The Incandescent Mantle Manufacturers' Association made their co plaint against four Continental importing countries—namely, Ge many, who were the principal competitors, and whose imports can in at the highest price; Poland, formerly a small competitor, b whose exports to this country were increasing in volume; and Aust and Italy, whose volume was comparatively small, but whose pric were lower than those of the other two countries. The Associati were informed, and believed it to be a fact, that it was to expect t importation of some two million mantles from Italy during the ne season. These were countries in which depreciation of currency h taken place two or three years ago, and where the currency had no become stabilized; but the depreciation which had occurred had le a permanent mark on the state of affairs in those countries, and ga the foreign manufacturer an advantage over his British competito particularly as to overhead charges. A more tangible ground f complaint against unfair competition was concerned with the inferi conditions of employment of labour, particularly in regard to wag The highest Continental figures for wages were 50 p.ct. below t wages paid in British factories. Lower wages also had an effect the price of raw materials, because the raw materials used in t mantle industry were the finished products of other industries, which the cost of labour entered very largely. Foreign competito were able to obtain their nitrate of thorium and other goods requir for manufacturing mantles, in the majority of cases, at prices lowe and in some cases considerably lower, than the prices paid for simil goods by British manufacturers.

The Committee were entitled to consider whether the industry in th country was being carried on with reasonable efficiency and econom Regarding this point, Mr. Soper referred to the evidence given the previous inquiry in this connection, as the result of which a du was imposed on foreign mantles under Part II. of the Safeguardin of Industries Act, 1921, and said that British manufacturers were no

etting a substantial increase in output per worker per hour, as ompared with the output at the time of the previous inquiry.

Then the Committee were entitled to consider whether the imposi- on of a duty on gas mantles would exert a seriously adverse effect n employment in any other industry using goods of the same class n production. The only way in which a duty on mantles could affect nother industry would be that, if the cost of mantles were seriously aised, it might raise the cost of lighting in factories where gas was sed as an illuminant; but, whatever duty was placed on imported nantles, it would not have that effect.

Finally, the Committee were asked to express an opinion as to whether the applicant industry had established a claim to a duty, and, so, what rate or rates of duty would be reasonably sufficient to ountervail the unfair competition. In this connection Mr. Soper ubmitted that a flat rate on mantles would be preferable to an *d valorem* duty.

With regard to employment, a table showed that the number of orkers employed in this country each week totalled over 3000 roughout 1920, and in the last quarter of 1921 there were 2230. The gure had dropped to 1211 in the second quarter of 1922; in the last uarter of 1923 there were 1979; and in the last quarter of 1924, 1760. When the duty on imported mantles came off, employment was re- uced, and the number employed at the end of April this year was bout 1540. These workers were employed directly in mantle manu- acture. It was difficult to estimate how many were employed in- irectly, but Mr. Soper produced a table showing the principal raw naterials used, and indicating the extraordinary ramifications of the ndustry and the indirect employment afforded.

The CHAIRMAN said one could not regard the mantle industry as one of the leading industries of the country.

Mr. *Soper* said it was not put forward as such. The Association egarded it as one of national importance, however, having regard to he nature of the goods produced.

The CHAIRMAN asked why it was of national importance that con- umers should be able to buy British mantles. If they could get them heaper from abroad, why should not they?

Witness said that, when war broke out, the industry was unable o supply either its own raw material or the finished mantles which he country required; and a very serious state of affairs had arisen, which served to emphasize the national importance of the industry.

It was essential that the industry should be maintained in such a state that it could supply the whole needs of the country in a time of emergency. The total sales of British mantles, less exports, between the years 1920 and 1924, showed an average annual sale of about 430,000 gross. Also, better mantles were being made every day, and they lasted longer than those made previously. The condition of industry affected the gas mantle industry, because a substantial number of mantles were used in factories. In support of the view that the gas mantle industry was not a dying industry, he said that statistics showed that the number of street lamps using gas in the country had increased from 697,000 in 1919 to 719,000 in 1924—an increase of over 20,000. The number of consumers of gas had increased in the same period from 8 millions to 8¼ millions. This showed an increasing demand for gas for lighting, as well as for other purposes. In the same period there was an increase of 336,000 users of slot meters, showing an increase in the use of gas among the poorer classes. Again, sales of gas lighting appliances had been increasing continually during the last two or three years. Another point which had a bearing on the demand for gas mantles, *qua* mantles, was the installation of clusters of lights in street lamps in place of a single light; and there appeared to be an increasing tendency to instal this system of lighting.

In reply to Sir John Barran, witness said that, if British mantles ceased to be made, the effect would be prejudicial to the production of gas in this country, and to the production of valuable products obtained from gas manufacture; because, if no gas mantles at all were available, gas as now manufactured would be useless as an illuminant.

Sir JOHN BARRAN said the Committee would want to know whether the gas could be used up in its entirety for cooking, even if it were not used as an illuminant.

In answer to a question, Mr. Soper said he did not think a duty would materially increase the price of mantles to the consumer, because he was not at present getting the advantage of the low prices of imported mantles. It was not proposed to offer evidence as to the control of export prices in Germany, which was an important matter at the previous inquiry, because there was no price association in Germany at present, and German manufacturers were importing independently, so far as he knew.

The Committee adjourned until Friday, May 22.

CAPETOWN AND DISTRICT GAS LIGHT AND COKE COMPANY, LTD.

Dividend Maintained.

The Thirty-Fifth Ordinary General Meeting of the Company was eld last Wednesday at the London Offices, No. 38, Grosvenor Gar- lens, S.W.—Mr. H. R. SAVORY (the Chairman) presiding.

The SECRETARY (Mr. R. W. Blackburn) read the notice convening he meeting and the Auditors' report; and the Directors' report and he statement of accounts for the year to Dec. 31 were taken as read.

The CHAIRMAN said that the year 1924 opened with rather better prospects for general trade in Capetown than previously, and busi- ess continued to improve for the first three months; but after- wards general trade declined, and it was not until near to the close of the year that there were any signs of improvement.

AN INCREASED PROFIT.

It was gratifying to the Directors that the report and accounts which hey submitted for approval that day might be considered satisfactory. The result of the year's working showed an increase in income and an increase in profit. The increase in income was not a large one; and the increase in profit was mainly due to economies in general working. The Company had had a full year of the use of the No. 2 installation of vertical retorts, through which 13,010 tons of South African coal had been carbonized. A saving of 1228 tons of coal had been made, and a larger output of gas had been obtained—14,884 c.ft. per ton. The decrease in coal used had resulted in a saving of £3220 in the cost of coal for last year. The coal used produced a good volume of gas, and the yields of coke and tar were fairly adequate.

REVENUE ACCOUNT.

Comparing the revenue account with that of the previous year, expenditure on manufacture and distribution had decreased £3125; the cost of repairs and maintenance of works, plant, and mains had been reduced £1141. These, with other smaller economies, resulted in a reduction of total expenditure of £3883. On the revenue side of the account, revenue from the sale of gas and rentals of meters, cookers, geysers, and other fittings showed an increase of £1302. Sales of fittings were £216 higher; but sales of residuals were less by £475. The profit for the year was increased by £4553—a result which might be regarded with satisfaction. The increase in the quantity of gas sold was equal to 1'3 p.ct., there having been a better demand for gas by the users of prepayment meters. On the other hand, sales of gas by ordinary meter and those to large consumers for industrial purposes were slightly reduced. This was due to the closing-down of several of the canning factories for many months, and also in some measure to the British Empire Exhibition at Wembley attracting visitors from Cape Town.

RESIDUALS.

The coke sales increased by 15,099 bushels last year; but the average price obtained was not quite so good—being 2d. per bushel below that of the previous year. Sales of tar were lower than in 1923, less tar having been made, owing to the smaller quantity of coal carbonized. But all the tar made was sold. The average price obtained for tar was less by ½d. per gallon. It was necessary to reduce prices of both these residuals, in order to compete with the import prices.

DISTRIBUTION.

There were 5873 yards of mains of various sizes laid last year—principally at Sea Point, at Green Point, and at Pinelands Garden City, enabling new properties to be connected and fitted for supplies of gas. Continuous and systematic search for faults in mains and services was carried on, and many repairs were executed. Gas for cooking and heating increased in popularity, and 249 new consumers were added during the year. The average value of ordinary meter consumers' accounts was less by 1s. 4d. than in 1923; but the average receipts by prepayment meters increased by 2s. 11½d. per meter. The policy of the removal of the showroom and offices into the business quarters of the city continued to be fully justified; increased numbers of cookers, stoves, geysers, and other fittings having been sold. The Company's system of propaganda for making known the various uses of gas by means of advertisements, posters at railway stations, and lectures with cookery demonstrations, had been steadily pursued. These demonstrations were so well attended that on some occasions the accommodation was insufficient for all those persons who wished to be present. The Pinelands Garden City Estate had been linked with the Company's mains by 6-in. pipes, and by the end of last year 66 houses had been connected and supplied with gas. They were now in a position to connect the new houses as erected; and the demand for houses continued to be brisk.

PROSPECTS.

Mr. Blackburn, a member of the Board, visited the Cape in the autumn of last year, and would presently give them an account of the conditions he found existing at Cape Town, and an indication of what were the prospects for increasing business by future extensions. As to the outlook for the current year, a steady increase in the number of consumers was being obtained. The working of the plant was very satisfactory, and the capacity amply sufficient to supply any increased demands. Applications for supplies of gas were being received and dealt with. It could not be expected that they would be able to continue indefinitely to make further large economies in the cost of working. They must look to increasing the number of their consumers, and to giving satisfaction to them, in order to maintain and increase revenue; and in this the additions to the mains already made, and those to be made this year, should be of very considerable assistance. He concluded by moving that the report and accounts be adopted, and that a final dividend of 4 p.ct., less tax, making, with the interim dividend already paid, 7 p ct. for the year, be declared on the ordinary shares.

MR. BLACKBURN'S ACCOUNT OF HIS VISIT TO SOUTH AFRICA.

Mr. R. W. BLACKBURN, in seconding the resolution, said that in view of his visit to Cape Town last year, it might be of interest if he touched as briefly as possible upon some aspects of the Company's business. The Chairman had told them that the manufacturing plant was now ample to meet all possible demands for some years, and that, although the output of gas had increased, some 1200 tons of coal were saved during the year—the average gas made improving to nearly 15,000 c.ft. per ton of coal carbonized. The calorific value of the gas supplied was not sacrificed in order to obtain this result. It was maintained throughout the year well above the Company's statutory standard, with a total absence of complaints. Now, in dealing with these results, it was fair to have regard to the fact that they had been obtained under what in this country would be termed somewhat adverse conditions. They used South African coal exclusively. Analyses of this coal showed a volatile content of some 30 p.ct. below that of a good average English coal, and an ash content very much higher. The coke produced, though of excellent quality, was subject to somewhat rapid attrition; and the tar yield also was not high. These factors, of course, affected the revenue from residuals. Coal had to be freighted by rail nearly 1000 miles, and during this long

transit a certain percentage was lost through windage and shaking. Notwithstanding these disadvantages, and the fact that residuals at Cape Town, in common with the rest of the world, commanded lower prices during the year, nearly 66 p.ct. of the cost of coal carbonized was recovered from the sale of residuals; and this, they would agree, reflected credit on the Engineer responsible for the working of the Company's plant. The improvement in working was more marked during the latter half of the year. He would add that, although the average results, compared with the previous year, were relatively good, this did not preclude the Board from expecting some further improvement during the current year.

CONDITIONS AT CAPETOWN.

Now to come to what at the present time was highly important—distribution. The conditions in which gas had to be supplied at Cape Town were very different from those obtaining here. Density of population was very much less. The majority of houses built were of the detached type, situate well back from the roads; and though from a residential aspect this offered advantages, it had disadvantages from the point of view of gas supply, and expenditure necessary in connecting-up new consumers. They would, perhaps, more readily realize the scattered nature of the districts served when he told them that the Company now had in Cape Town and suburbs over 120 miles of mains in operation, supplying some 6200 odd consumers. Building was proceeding apace. Electrification of the railways was projected, and new districts are rapidly being opened-up; and if advantage is to be taken of these opportunities, if the Company's business is to expand, and to continue to progress satisfactorily, it is obvious that they are faced with very considerable further expenditure. The question of extensions was one of the several important matters which necessitated his visit to Capetown last year when the whole position of the Company's business, its prospects and possibilities, were exhaustively reviewed. As a result, a definite policy had been formulated, and within the limits of their resources was being carried out. From the closer, and, he hoped he might say, very cordial co-ordination established in the Company's affairs, the Directors were reasonably expecting in the near future considerable further improvement of business on the distribution side. He was particularly pleased with the design and lay-out of the showrooms. They were situate in an admirable position, in one of the two best business thoroughfares in Cape Town. They had heard from the Chairman that 249 new consumers were obtained during the year. He would amplify this by telling them that 468 gas cooking appliances, 222 geysers, and 46 gas fires were installed in 1924. The demonstration of gas appliances, &c., at the showrooms had undoubtedly proved of great benefit, and had helped also in regard to the development of gas for industrial purposes. This latter branch was being systematically pushed. They already had some very considerable new consumers; and the prospect of further good business was encouraging. In these times he would not care to risk any prophecy. He thought, however, from what he had said they would agree that signs were apparent which pointed to steady progress—with this proviso: That the Union of South Africa, and more particularly Cape Town, as affecting the Company's activities more closely, remained free from further ill-advised industrial disturbance of trade and commerce, such as the strike which held up all business in the building and allied trade for over two months during his visit.

ADMINISTRATION.

From the accounts before them, it would be seen that the position was very healthy, compared with even a few years back. He wished to emphasize one important point. They had not made any capital borrowing during the year to meet the cost of extensions. This cost had, up to the present, been financed out of income. They would see from the balance-sheet that cash in hand at Dec. 31 last, amounted to in round figures £5000—just about sufficient to meet accrued interest on debentures payable on Jan. 1 of this year. They had spent to the limit of their resources. There was no margin; and in this fact, he thought, lay the answer to what he might be permitted to call the somewhat pointed inquiries which he had received from several shareholders on the question of dividend distribution. It was, of course, obvious that, but for the expenditure on extensions to which he had alluded, a larger distribution on the ordinary shares than the one now recommended would be possible. The Directors were very considerable shareholders; and Mr. C. W. Lilley controlled what was by far the largest individual shareholding in the Company. They would all be pleased to receive a higher rate of dividend; but, after very careful consideration, it was clear to the Board that what might be termed a conservative policy in this respect must be adhered to during such time as extensions had to be dealt with out of income, and until the period arrived when this outlay bore fruit. The aim had been to pay a dividend which could be counted upon as stable, not liable to fluctuations—at any rate, not to fluctuation in a downward direction—and the dividend of 7 p.ct. now recommended was in accordance with this policy. It was one which he hoped they would thoroughly endorse. During his stay in Cape Town, he, of course, came into every-day personal contact with all grades of the employees. He took this opportunity of acknowledging the keen interest shown in all that could assist the progress of the business by the Local Consulting Director, Dr. Bennie Hewat. He was a gentleman who was very conversant with all Union conditions, and particularly with local affairs at Cape Town; and in any matter likely to affect the Company's interests he was always available for consultation and advice. Their Cape Town Auditors have acted for the Company for a very long period, with entire satisfaction to the Board. Their checking and audit of the accounts there was very thoroughly carried out, and he would like to say that their Chairman (Mr. E. R. Syfret) was of very considerable assistance to him in some important matters of the Company somewhat outside the usual scope of his firm's services. For this he was personally extremely indebted to him, Mr. Syfret; and the Board very much appreciated it. In concluding, it was fitting that he should pay a tribute to the good work during the year under review of the General Manager, Engineer, Distribution Superintendent, and their respective staffs at Capetown and Woodstock. The aim, and endeavour, of a public utility undertaking such as theirs was, should be to supply the public it served with gas and residual products of excellent quality, coupled (equally as important) with efficient and courteous service. As a result of attention to this policy, the undertaking now enjoyed, and deservedly enjoyed, a high repute. Such a standard could not have been attained, and it certainly could not be maintained, without the energy, the zeal, and above all the loyal co-operation displayed by the Company's employees; and he was pleased to be able to report, from personal observation and from other sources available to him, that the business was so capably and so loyally served by its responsible officials and the general staff.

Mr. A. R. Burch said that, as an old Gas Engineer, he would like to endorse what Mr. Blackburn had told them with regard to the difficulty of making gas out of what was really steam coal, instead of gas coal. Had the Board ever investigated the possibility of obtaining coal from Australia? The conditions described by Mr. Blackburn revealed an excellent field of high-pressure distribution, which meant a smaller outlay on mains. As to the dividend, the price charged for gas was high; and the great object should be to decrease it in every way possible.

Mr. E. Nicholls regarded the report as exceedingly satisfactory. The policy of sending out Mr. Blackburn to inquire into things on the spot was very much to be commended; and if this plan was followed from time to time, so as to keep in closer touch with affairs out there, it would be an advantage.

Mr. A J. Kingdon asked what was the total quantity of gas sold during the year. He congratulated the Directors on the report and accounts, and trusted they would continue the wise policy of augmenting the reserve fund until the Company was placed in a strong financial position.

Mr. Whittaker inquired as to the percentage of unaccounted-for gas.

Mr. Blackburn replied to these questions, and to one or two remarks regarding the accounts. He said the Company had at the present time no capital available for undertaking high-pressure main extensions. The extensions which were being undertaken at the present time were those which came within the radius of existing mains. The manufacturing plant was ample; and it was only by increasing the consumption on the existing mains that they could hope for augmented profits. The total sale of gas was 155 million c.ft. in round figures. They had spent over £9000 on extensions during the year; the bulk was on distribution account. Gas unaccounted for per mile of main was, he thought, fairly comparable with that of any gas undertaking he knew of—200,000 c.ft. The sudden variations of temperature in Cape Town had to be taken into consideration in this connection.

The resolution was then put to the meeting and unanimously carried.

Mr. C. W. Lilley proposed the re-election of Mr. Blackburn as a Director. He pointed out that Mr. Blackburn had been appointed to the Board while acting as Secretary, which position he had filled for many years. When he became a Director, it seemed to the Board very desirable that his great knowledge and experience of the business should be utilized in a visit to Cape Town. From this visit the Board hoped to get good results in the future, as he believed they had done already.

The Chairman seconded the motion, which was agreed to.

The Auditors (Messrs. Kemp, Chatteris, Nichols, Sendell, & Co.) were, on the proposition of Mr. Kingdon, seconded by Mr. Whittaker, reappointed, at a fee of 100 guineas, in place of 80 guineas as heretofore; and the proceedings terminated with votes of thanks to the Chairman, Directors, and staff, both in this country and South Africa, for their excellent services to the Company.

Shrewsbury Gas Light Company.—At a meeting of the Shrewsbury Town Council last week, Mr. L. Jackson moved the following resolution: "That the Council is of opinion that in the interests of the townspeople, the undertaking of the Shrewsbury Gas Light Company should be the property of the Corporation, and instructs the Finance, General Purposes, and Parliamentary Committee to bring up a report to the Council on the matter at the September meeting of the Council."

Discontinuance of Public Lighting at Hereford.—The Hereford Town Council have decided to discontinue the public lighting during the summer, with the exception of twelve 1500 c.p. lamps situated in the principal squares and at dangerous corners. These will be lighted from dusk till dawn. The cluster burners in 24 sewer lamps will be plugged-up, with the exception of one nozzle in each lamp. One No. 2 nozzle in each sewer lamp will be kept alight (with mantle) night and day, primarily for sewer-gas extraction purposes. The discontinuance of the bulk of the public lighting is from May until the first week in September, when the lamps will again be lighted from dusk till midnight.

Progress at Spalding.—Reference was made in the Spalding Urban District Council, by the Chairman of the Finance Committee, to the continuous progress of the Gas Department. The make during the past financial year, he said, was 80,282,000 c.ft., which was an increase of 3,450,000 c.ft. over the previous year; and this, bearing in mind the steady rise in output over the preceding four years, was very gratifying. The system of selling gas cookers by hire-purchase, which had been adopted on the suggestion of the Manager (Mr. R. J. Calderwood), has proved very successful; and much is hoped from the fine new showrooms. The Chairman cited the reasonable charge for gas—large consumers for power purposes can obtain it at 3s. per 1000 c.ft.—as proof of the admirable way in which the gas undertaking is managed.

STRETFORD AND DISTRICT GAS BOARD.

n exhibition and series of cookery demonstrations has recently held at the Public Hall, Urmston.

he Chairman of the Board, Councillor R. J. M'Beath, J.P., ., in opening the exhibition on May 4, said that the object was ive the consumers of the district an opportunity of obtaining in- ation how to make the best use of the gas supply in their homes. e the Board took possession of the gas-works at Stretford, the ber of cookers in use in the area had increased from 4700 to ly 8000, and the number of fires from 3000 to 3700. The total made in the last complete year prior to the Board's possession of works was 518¾ million c.ft.; and for the year ended March 31 700 millions had been manufactured. Gas used for industrial pur- s has increased from 114 million to 166¼ million c.ft. In order ring special patterns of highly-finished cookers, fires, water- ing apparatus, and wash boilers within the reach of all con- ers, the Board had introduced a hire-purchase system. uring the run of the exhibition Miss H. H. Tuxford, M.C.A., demonstrations in cookery by gas; and the visitors benefitted he instruction and help given.

TRADE NOTES.

srs. Firth Blakeley, Sons, & Co.

This firm have published a booklet in which are illustrated some he plant they manufacture. Several of the photographs refer to rent types of gasholders.

rection.

In our "Trade Notes" last week a new catalogue issued by srs. W. C. Holmes & Co., Ltd., was mentioned. In this reference made to the Wikner system. Unfortunately the name Wikner mis-spelt.

erro-Concrete Structures for Gas-Works."

This is the title of an illustrated booklet recently issued by the . Construction Company, Ltd., of Derby, which contains particu- and photographs of some of the many contracts which the firm successfully carried out.

m Dryers.

Messrs. James Gordon have published a new leaflet dealing with Massip steam separator or dryer. Thousands of these separators at work, and they have been adopted largely in this country by ing engine builders, such as Messrs. Sultzer, Bros., John Mus- e & Sons, Ltd., and Galloways, Ltd. These appliances are of ish manufacture throughout.

ent Fondu.

The Lafarge Aluminous Cement Company, Ltd., of Lincoln se, Nos. 296-302, High Holborn, W.C. 1, have published an resting booklet dealing with their special product, Ciment Fondu, h is a high-aluminous cement giving extremely high compression ngth at twenty-four hours. The pamphlet gives comprehensive concerning its discovery, qualities, and its fundamental difference Portland cements. It also indicates cases where much time t be saved, and reduction in costs effected, by its use. The phlet will serve as a handy little book of reference for engineer, ractor, and architect.

CONTRACTS OPEN.

.

The Gas Committee of the Sutton-in-Ashfield Urban District ncil are inviting tenders for the supply of 8000 tons of gas coal. advert. on p. 618.]

The Newbury Corporation Gas Undertaking are inviting tenders South Yorks. and Derbyshire gas coals for a period of twelve ths. [See advert. on p. 618.]

The Council of the Urban District of Spenborough are inviting ers for the supply of about 20,000 tons of screened gas coal or for their Cleckheaton and Heckmondwike Gas-Works. [See rt. on p. 619.]

The Hebden Bridge and Mytholmroyd Gas Board are inviting ers for the supply of 7000 tons of gas nuts. [See advert. on p. .]

The Gas Department of the Clacton-on-Sea Urban District ncil are inviting tenders for the supply and delivery of 6000 tons st screened gas coal. [See advert. on p. 618.]

rts (Horizontal and Vertical), **Retort Houses, Coal and Coke Handling Plants, &c.**

Tenders are invited by the Gas Committee of the Manchester oration for horizontal and vertical retort installations, retort es, and coal and coke handling plant, &c. [See advert. on p. 618.]

fiers, Connections, &c.

The Gas Committee of the Manchester Corporation are inviting rs for purifiers, connections, and lifting apparatus. [See advert. 618.]

Reduction in Price at Sedgley.—The Sedgley Urban District ncil have decided to reduce the price of gas commencing with the nt quarter. The charges will now be 4s. per 1000 c.ft. to ary consumers, and 16 c.ft. per 1d. for slot consumers.

Croydon Gas Company's Co-Partnership.—The report of the Co- nership Committee for the year ended March 31 last has been d. The bonus is at the rate of 6½ p.ct. (the same as for the ous year), being the average rate at which dividend was paid on liding-scale stock of the Company for 1924. Up to March 31, the inception of the scheme, in 1909, 1541 co-partnership agree- s have been entered into, and 660 have terminated, leaving 881 in .

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

By almost common consent, the past week has been the worst so far experienced, at all events, as far as Durham is concerned. Northumberland steams were weaker all round, and in most cases about sixpence lower than in the previous week. There appeared to be no interest in Durhams at all, and it was more a question of entire absence of demand than of price.

Production will be curtailed this and next week owing to Whitsun holidays, but it seems extremely doubtful whether this will affect the position at all. Inquiry is entirely lacking, both for prompt and forward shipment.

Wear Specials and the best quality gas makes are quoting 19s. f.o.b., but few are in a position to hold out for this price except by working short time. Seconds are 16s. 6d. to 16s. 9d. Unscreened coking is an extremely weak market, and best sorts are obtainable at 16s. 9d. to 17s. Best Durham bunkers are offering at 17s. to 17s. 6d. But, as already stated, there does not seem to be enough trade at any price, and, even at these lower levels, collieries are faced with idle time, and more and more notices are being given on all sides. Still, some sections of the miners at the delegate conference last week were in favour of proceeding with additional wages demands, though it is true they were in a minority. The policy of the less optimistic majority appears to have been to hold on to what they have got as long as they can. But more than this will have to be done to reduce our costs to a competitive level.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

There is no material alteration in the Yorks. and Lancs. coal market this week. The irregular working of collieries is likely to continue, partly because of the lack of export business which in normal times relieves the market of superfluous screened coal.

The industrial outlook continues black, and the position is worse than it was some months ago; the iron and steel trades being particularly affected. As a result, many collieries have on hand stocks of the smaller grade fuels; and these are being offered at discounted figures without apparently bringing about the desired results. Consumers have difficulty in taking even their limited contract deliveries.

Gas coals continue to be inquired for under contract for delivery over twelve months beginning either in July or August, and the general attitude of producers appears to be one of uncertainty. Figures for the same class of coal vary at different points in accordance with the local situation.

The shipping outlook shows no improvement; and should the present situation continue, there will be a serious financial proposition for the collieries to consider in view of the larger outputs which Germany is producing and selling to customers who previously took British coal.

The following are the Humber bunker and export prices (f.o.b. usual shipping ports): South Yorkshire—Hards, Association, 20s.; screened gas coal, 18s. to 18s. 6d.; washed trebles, 19s. 6d. to 20s.; washed doubles, 17s.; washed singles, 16s.; washed smalls, 11s. 9d. to 12s. 3d.; unwashed doubles, 16s.; rough slack, 10s. to 10s. 6d.; smithy peas, 19s. to 20s. per ton. West Yorkshire—Hartleys, 17s. to 18s.; screened gas coal, 17s. 6d. to 18s.; washed trebles, 18s.; washed doubles, 16s. to 17s.; washed singles, 15s. 9d. to 16s. 3d.; washed smalls, 11s.; unwashed trebles, 17s. to 17s. 6d.; unwashed doubles, 13s. to 14s.; rough slack, 10s.; coking smalls, 8s. 6d. to 9s. per ton. Derbys and Notts.—Top hards, 20s.; washed trebles, 17s. to 19s.; washed doubles, 16s. 6d.; washed singles, 15s. 6d.; washed smalls, 11s.; unwashed doubles, 14s. to 15s.; rough slack, 10s. to 10s. 9d. per ton. Yorks, Derbys, and Notts.—Screened steam coal, 15s. to 17s.; gas coke, 20s. to 21s. 6d.; furnace coke, 15s. 9d. to 16s. 9d. per ton.

The highest classes of Lancashire slack are selling at from 15s. to 17s. per ton at the pits. Industrial coal is 21s. per ton at the pits.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

The anxiety of collieries to keep down stocks results in the market being inundated with supplies—offered in many cases at prices appreciably lower than those previously ruling. Endeavours are being made to impress householders with the advantage of filling their cellars at these low rates. Very little success attends these efforts, however. Last year, when the buying of domestic supplies for the winter was accelerated in some measure, householders who procrastinated had to pay for their indecision, the rush of demand which followed the holiday season giving a sharp impetus to prices. It is difficult to enforce the lesson, however, in the present glutted state of the market. Bakers' nuts can be bought at the normal price of good slack. All grades of industrial fuel reflect market deterioration. It is a common complaint that wagons are not earning anything like sufficient to make ends meet. In the circumstances which prevail, long railway hauls represent such a disproportionate ratio of cost that pits remote from the big centres of consumption are very badly hit. It is these that are cutting the prices so severely. Even the more favourably placed collieries, which have been comparatively well employed, are now retarding the rate of output. More contracts for gas coal supplies over the coming year have been fixed up. Some of the undertakings are attracted by the expedient of balancing the arrears which have to be made up on current contracts with the low-priced spot lots that are being offered; but the question of storage presents a formidable obstacle. Generally "safety first" is the ruling factor. The market continues over-supplied with both gas coke and furnace coke, with the inevitable effect on values.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *May* 25.

Pitch is nominal at 41s. to 42s. per ton. There is a certain amount of inquiry developing for next season's shipment, but makers are disinclined to sell at present low levels.

In the meantime chief interest is concentrated on road tar, which is being delivered in large quantities.

There is more inquiry for creosote, and the price is steady at about 7d. to 7½d. per gallon net and naked at works.

Pure benzole and pure toluole remain unchanged at about 1s. 11d. to 2s. per gallon.

Solvent naphtha is firm at 1s. 8d. to 1s. 9d. per gallon for 95-160 quality.

Tar Products in the Provinces.

May 25.

Tar products markets are generally unchanged and quiet, and there is very little inquiry for either prompt or forward delivery. So far as pitch is concerned, shipments appear to have ceased for this season. As regards business for next season, prices are so low that there is no inducement to manufacturers on this side to sell. So far as buyers on the Continent are concerned, they appear to be quite willing to wait unless they can get on at something like the equivalent of 40s. a ton f.o.b.

Creosote continues quiet; but there is a steady demand, and it is generally thought that some improvement in price will take place when the export demand improves, which it is expected to do about the turn of the half-year.

Water-white products are steady, and there is still a good demand for solvent naphtha.

Crude carbolic and cresylic continue dull, and there is little or no business passing.

The average values for gas-works products during last week were: Gas-works coal-tar, 26s. 3d. to 31s. 3d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8½d.; crude, 65 p.ct. at 120° C., 11d. to 1s. 1d., naked at makers' works: 50-90 p.ct., naked, North, 1s. 7½d. to 1s. 8½d. Toluole, naked, North, 1s. 6½d. to 1s. 7½d., nominal. Coal-tar crude naphtha, in bulk, North, 7¾d. to 8¾d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 5¾d. to 6d.; salty, 5⅝d. to 5¾d.; Scotland, 5¾d. to 5⅞d. Heavy oils, in bulk, North, 6½d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

RATING AND VALUATION.

The New Bill.

The Government scheme for the amendment and simplification the law relating to rating and valuation has recently been issu Naturally, in view of the complexity of the subjects dealt with, measure is somewhat technical in character. It consists of seven eight clauses and nine schedules.

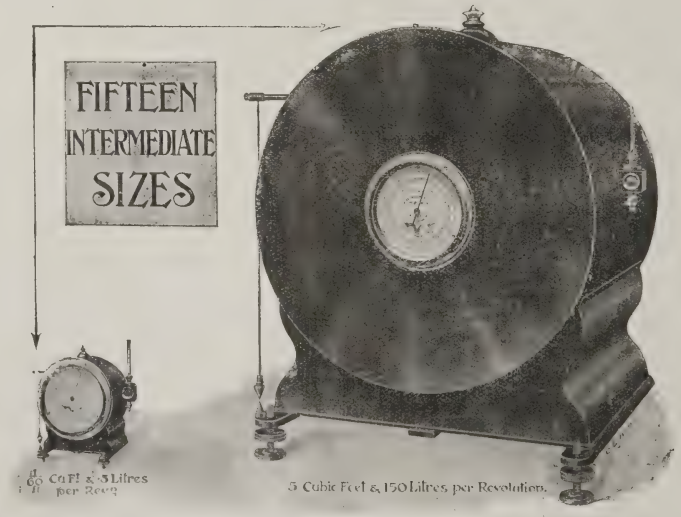
The main objects of the Bill are the simplification and improvem of the administrative machinery of rating and valuation and the moval of various anomalies; the substitution of a single valuati for the separate valuations at present required for purposes of rati and taxation; and the promotion of uniformity of valuation as a co dition precedent to any comprehensive review of the system of lo taxation and Exchequer grants. Parochial rating is to be abolishe the rating functions of overseers are to be transferred to town counc and district councils, and boroughs and urban and rural districts st stituted for parishes as rating areas. The appointment of overse will be discontinued, and all paid parochial officers will be transfer to the new rating authorities. Rates are to be consolidated. boroughs and urban districts a "general rate" will take the pl of the separate rates now levied; in rural districts there will be "general rate" levied by the rural district council over the wh district in place of the poor rate, and a special rate levied on ea parish chargeable with special expenses under the Public Health Ac or lighting expenses under the Lighting Act. Various amendme are proposed for the simplification of procedure in regard to the le ing, operation, incidence, collection, and compounding of rates.

As to the single valuation, it is proposed that, as is already case in the Metropolis, the values should be the basis for the asse ment of county as well as local rates, and that the gross val appearing in the valuation lists should be adopted for the purposes Schedule A of the income-tax. Inland Revenue officers will accoingly be concerned in the preparation and revision of the valuat lists. It is proposed that valuation areas should consist of (*a*) cou boroughs, and (*b*) county districts or combinations of such distri and that there should be one assessment committee for each ar Following the London precedent, the valuation list is to be renew every five years.

In accordance with the recommendations of the Inter-Departmen Committee whose report was issued in February, the Bill propos important changes in the matter of the rating of machinery. It provided that the following classes of machinery and plant are to deemed to be part of the hereditament:

1. Machinery and plant (together with the shafting, pipes, cab wires, and other appliances and structures accessory thereto) wh is used or intended to be used, mainly or exclusively, in conn tion with any of the following purposes: The generating, stori

LABORATORY METERS.



ALEXANDER WRIGHT & CO., LTD.,

Telegrams: Precision, Vic.

WESTMINSTER.

Telephone: Victoria 1207.

transforming, or transmitting of power, heating, cooling, ventilating, lighting, draining, or the supplying of water to the land or buildings of which the hereditament consists, or any part of that land or those buildings, or the protecting of the hereditament from fire.

. Lifts and elevators.

. Railway and tramway lines and tracks.

.. Any plant or any combination of plant and machinery which is, or is of the nature of, a building or structure, including gasholders, blast furnaces, coke ovens, tar-distilling plant, cupolas, water towers with tanks.

With the above exceptions, no account is to be taken of the value of any plant or machinery, which will therefore be exempted from rating.

In the Bill the gas industry will find several matters which will have to receive the consideration and action of its central organizations.

Langley Mill Gas-Works Extension.

The Langley Mill and Heanor Gas Company, Ltd., are installing another large gasholder at their Langley Mill Works. This is to be erected close to the one installed a few years ago, and, like it, will have a capacity of 260,000 c.ft. The work of construction is being carried out by Messrs. Robert Dempster, Ltd., of Elland; and for the riveting special hydraulic plant has been laid down. An interesting ceremony took place recently, when Mrs. Andrews, wife of Mr. H. J. Andrews, Managing Director, put in the first rivet, and was presented with a gold-mounted umbrella as a memento by Mr. J. Earside, the Engineer-in-Charge.

Rotherham Corporation Gas Department.

The annual report of Mr. J. S. Naylor, the Engineer and General Manager, for the year ended March 31, shows that the quantity of coal carbonized during the year was 9291 tons, as against 6847 tons last year. The gas made was 124,628,000 c.ft. (623,140 therms), compared with 94,642,000 c.ft. (473,210 therms) last year—an increase of 29,986,000 c.ft. The quantity of gas purchased was 226,401,100 c.ft.—a decrease of 16,573,000 c.ft. The quantity of gas sold was 222,448,000 c.ft., an increase of 12,766,000 c.ft., or 4·12 p.ct. on last year's figures. This is mainly due to the increased demand for gas fires and cookers. The gross profit was £14,765, as against £16,956 last year. The net profit, after allowing for interest, redemption instalments, and contributions to sinking fund, amounts to £2459, compared with £4707. Owing to the reduction in the price of gas (4d. per 1000 c.ft.), which took effect at the beginning of last year, the saving to the consumers was £5374.

Sale of Nuneaton Gas Shares.—At the Peacock Hotel, Nuneaton, on May 19, Messrs. T. J. Chinn & Son sold by auction a number of shares in the Nuneaton Gas Company, the prices realized being as follows: 60 original £8 shares (7½ p.ct.), £6 10s. each; 50 new £8 shares (5¼ p.ct.), £4 10s. and £4 15s. each; and £100 of debentures, at £67.

The half-yearly report of the Matlock Bath gas undertaking shows a gross profit of £260, but a net loss of £365.

The Dewsbury Corporation Gas Department have made a net profit of over £7000 during the past year, despite the depressed condition of the residuals market.

A proposal was made at a meeting of the Brigg Urban Council that the Gas Committee consider reducing the price of gas. It was stated that, as new purifiers would have to be purchased, this concession could not be made.

In his annual report, Dr. W. A. Daley, Medical Officer of Health for Blackburn, refers to the fact that the average deposit of soot in the centre of the town is 48 metric tons per month, and states that an increased use of gas for power, lighting, and heating is necessary.

The Coventry Gas Committee have recommended to the City Council "that a scheme for the treatment of the effluent from the Foleshill Gas-Works be approved at an estimated cost of £15,000, to be paid from the reserve fund; and that an increased scale of charges be approved."

A dinner was given last Friday, at the Veritas Mantle Works, Wandsworth, by the Directors of Messrs. Falk, Stadelmann & Co., Ltd., to celebrate the winning by the Veritas Football Club First Team of a cup and medals for Group A, and a cup for the League Championship, Balham and District League, and by the Second Team of the runners-up certificate for Group C.

At the Ellesmere Port Gas-Works, on May 20, Mr. W.O. Parkinson and Mr. W. Stockton set in motion two engines for pumping gas into the holders at Little Sutton. The Ellesmere Port and Whitby Urban Council recently acquired the Sutton and Hooton Gas-Works, and the areas now supplied are Little Sutton, Great Sutton, Childer Thornton, Hooton, Eastham, and Willaston.

A verdict of "Accidental death" was returned at an inquest at Bristol on Thursday on Robert William Pratt, a stoker at the Thornbury Gas-Works, who died in the Royal Infirmary following an accident at the works. Evidence was given by Mr. Charles William Buckingham (the Manager) that the accident happened in the purifier house, where there were three boxes with lids removed by a traveling crane. To operate the crane, workmen had to get on the top of a box, and push it along. Witness heard a noise, and on going to investigate what had caused it, found that the crane had fallen over, and that Pratt was lying on his back between two of the boxes. Witness believed the accident was caused by deceased having pulled, instead of pushed, the crane, and not doing it squarely made it topple over. He had been instructed as to how to use it. Witness admitted that there was no first-aid equipment at the works; and in returning their verdict, the Jury expressed the opinion that such appliances should have been provided.

STOCK MARKET REPORT.

On the Exchange last week there were signs that business was a little more active, influenced doubtless by the improved monetary outlook. As we anticipated, the London County Council issue did not attract the public, and 75 p.ct. was left with the underwriters. Frantic efforts are now being made to unload both the Council and the New Zealand loans, and several boosting paragraphs have appeared in the financial Press. Quite another proposition is the New South Wales issue of £6,500,000 5 p.ct. loan at 98½ p.ct., which was underwritten on Friday last, and for which it is expected there will be an enormous demand. Gilt-edged stocks were firmer. The result of the miners' conference has had an improving influence on the Home Rail Market, although the reduced traffic returns are not encouraging.

On the whole Industrials were quiet. The proposed modification of the Silk Duties brought about a recovery in Courtaulds, British Celanese, and Grouts. Iron and Steel issues were stimulated by the excellent report of the Tata Company, and Armstrongs improved on increased business reports.

The Gas Market was distinctly disappointing. It was thought that prices had steadied; but, as will be seen by the Table, all the changes in the quotations were on the downward grade. Ignoring the big *ex* div. drop of 27 points in the Imperial Continental Capital Stock, the principal reductions were the Brentford "A" and "B" stocks, which are now quoted at 95-100, a drop of 2½ points, the South Suburban 5 p.ct. ordinary at 95-98, a drop of 3 points, and Tynemouth 74-76, a drop of 3 points. The fall in the South Suburban stock is doubtless due to the proximity of the announcement of a reduced standard price.

An issue by tender of £30,000 6 p.ct. Irredeemable Preference Stock at a minimum of par is announced by the Lea Bridge District Gas Company. There should be a good demand for this stock.

The following transactions were recorded during the week:

On Monday, Bombay 5½ *ex* div., Brentford "A" 95, European 7, Gas Light and Coke 83¼, 83⅜, 83⅝, 83¾, 84, 84⅛, 4 p.ct. preference 78½, 3 p.ct. debenture 60⅜, Imperial Continental 182½, 183½, Ottoman 2s. 6d., Primitiva 9s. 3d., 9s. 6d., South Metropolitan 93¼, 93⅜, 93⅝, 93¾, 6½ p.ct. debenture 103, South Suburban 5 p.ct. debenture 98, 98½, Tottenham "B" 96½. Supplementary prices, Ottoman 7 p.ct. preference 58, Tottenham 5½ p.ct. preference 104¾.

On Tuesday, Alliance and Dublin 66⅛, 66¼, 66½, 4 p.ct. debenture 66⅜, 66½, Brentford "A" 95, British 4 p.ct. debenture 76, Commercial 4 p.ct. 87½, Continental Union 35⅝, 36, Gas Light and Coke 83¼, 83½, 83⅝, 83¾, 84, 84⅛, 4 p.ct. preference 78⅝, 79, 3 p.ct. debenture 60⅛, 60¾, 61¼, Imperial Continental 182½, Primitiva 9s., 9s. 1⅛d., 9s. 6d., 4 p.ct. debenture (1911) 64⅜, 65¼, South Metropolitan 93½, Tuscan 22s. 6d. Supplementary prices, Wandsworth 3½ p.ct. new 95, 5 p.ct. preference 95, 4 p.ct. debenture 77.

On Wednesday, Bournemouth "B" 12⅜, Brentford 4 p.ct. debenture 78, 79, British 112, 112½, Commercial 87½, Continental Union 36, Croydon maximum dividend 82¼, 83½, Gas Light and Coke 83½, 84, 84⅛, 84½, 3½ p.ct. maximum 63¼, 63⅝, 64⅜, 4 p.ct. preference 79½, Imperial Continental 182, 3½ p.ct. debenture 73, 73½, Primitiva 9s. 3d., 9s. 6d., 4 p.ct. debenture (1911) 64⅜, South Metropolitan 93⅛, 94, Tottenham "B" 97. Supplementary prices, Tottenham 5½ p.ct. preference 104½, 104⅝.

On Thursday, Bournemouth "B" 12⅜, Brentford "A" 95½, "B" 95, British 110, 111, Continental Union 36, Gas Light and Coke 83⅜, 84⅛, 84½, 3½ p.ct. maximum 63¾, 4 p.ct. preference 79, 79½, Hastings and St. Leonards 3½ p.ct. converted 76, Imperial Continental 155, 155½ *ex* div., Primitiva 9s. 3d., 9s. 6d., 4 p.ct. debentures 80⅜, 81, 4 p.ct. debenture (1911) 65¼, South Suburban 95. Supplementary prices, Wandsworth 4 p.ct. debenture 79.

On Friday, Alliance and Dublin 64⅛, 66¼, 66½, Gas Light and Coke 83½, 83⅜, 84¼, 84½, 3½ p.ct. maximum 64, 4 p.ct. preference 79½, 3 p.ct. debenture 61⅛, Imperial Continental 155, 155½, 156½ *ex* div., Primitiva 9s. 6d., 4 p.ct. debenture (1911) 65⅜, South Metropolitan 93½, Tottenham "B" 97. Supplementary prices, Wandsworth 3½ p.ct. new 95.

The success of the restoration of the Gold Standard seems to be now assured, and the fears of an increased Bank Rate have receded into the future. Conditions in the short loan market are extremely good, and the position will possibly become easier by the War Loan interest distribution at the end of the month. Balances were available at the end of the week at 3½ p.ct. The Treasury Bill average rate dropped nearly 4s. on the week to £4 9s. 5·9d. p.ct. This rate is still very high, and it is anticipated that ensuing weeks will show an improvement from the Government's point of view.

On the Foreign Exchange Market the dollar-sterling weakened to 4.86 1/16. Both francs and lire were lower in value. The Paris cheque closed at 94.77½, Belgian francs at 97.27½, and Italian lire at 120 3/16. Neutral exchanges generally moved in favour of this country.

The price of gold remained unaltered at 84s. 11½d., and silver on Chinese orders rose ⅛d. to 31⅛d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

OFFICE: 11, BOLT COURT, FLEET ST., LONDON, E.C. 4.

VOL. CLXX., No. 3238.] WEDNESDAY, JUNE 3, 1925. [77TH YEAR.

INSTITUTION MEETING

A complete account of the week's proceedings will appear in the single issue of the "JOURNAL" published on June 17.

EDITORIAL NOTES.

More Interest for the Institution Meeting.

s the days pass, the arrangements for the annual meeting f the Institution of Gas Engineers gather more and more nterest. The prospect is that numerically the meeting ill be equal to the best of records. The acceptances for nctions and visits show this. For example, those who ave signified their intention of visiting either Fulham, the outh Metropolitan Chemical, Physical, and Burner aboratories, or the National Physical Laboratory on hursday afternoon total something like 450; and the resident (Mr. J. Ferguson Bell, M.Inst.C.E.) and his hairman and Directors will have the felicity of welcoming Derby on the Friday approximately 420 visitors. At the ening meeting, the expected attendance is between 600 nd 700. A number of distinguished visitors as well as embers from overseas will also be present; and they ill have a warm reception from the members who carry n the work of the industry at home. On behalf of the sitors, there will be response to the welcome of the Presint by the Rt. Hon. J. H. Thomas, M.P., the Rt. Hon. r Alfred Mond, President of the Society of British Gas dustries, and Mr. W. Woolley (Chairman of the Derby as Light and Coke Company); and on behalf of the overas visitors, the Hon. George Swinburne, of Melbourne, ll reply. Among other matters of outstanding personal terest will be the presentation of the Birmingham Gold edal to Dr. Charles Carpenter, C.B.E., M.Inst.C.E.; d the members will take advantage of this opportunity give expression to their unanimous views as to the aluable work over long years that Dr. Carpenter has ccomplished for the gas industry. The winners of plomas in the recent Institution examinations in Gas ngineering will be personally presented with their certifites at the meeting; and they will have the further ward of receiving the massed congratulations of the mbers. The names of the successful diploma candites are given in later columns. The technical proamme for the meeting, with other features, have been eviously dealt with; and elsewhere to-day we publish Council's annual report, which shows a year of great tivity, with resulting additions to knowledge beneficial our industry.

The Campaign.

E gas industry is heading a campaign—not only in its n interests but in those of the nation, and, we verily lieve, of the electricity supply industry. It was opened Mr. D. Milne Watson, in the Presidential Address to Society of British Gas Industries which we reported d commented upon last week; and it was continued by n, with further effective point, in the address which delivered at the annual meeting of the National Gas uncil yesterday week. We cannot have too much icism, nor too much publicity, in respect of this urgent l momentous matter of the intentions of the Government in regard to electricity. Right at the initial stages of this campaign, however, it is necessary to proclaim frequently and widely that the gas industry has no fear of, and, of course, it has no valid objection to, the development of the electricity industry by its own exertions, merit, and resources; but the position has been transformed by the prospect of legislative preference and State aid, and that on altogether chimerical grounds. The situation is such that any scheme which the Government may propose, if State aid or legislative preference is involved, must be resisted to the fullest extent of the power of the gas industry; and more particularly as not a particle of national advantage has been or can be shown. On the contrary, in view of the absurd emanations of certain political imaginations, the prospect is a distinct national disadvantage, which in its incidence will seriously involve the gas industry as taxpayers and competitors of the electricity industry. Competition on level terms is an excellent thing; if the Government throw their weight on one side to the detriment of the other, they will be doing something which is both unjust and unwise. There is a possibility upon which there has not been any direct comment: It is, if experience should show that harm instead of benefit has been imposed by statutory process and State aid upon the electricity industry, its patrons, and the country, will there then be further relieving subsidies from the Government? That is a possibility which must not be overlooked.

The objections of the gas industry can be based on five grounds: (1) That, in view of the statements of ministerial spokesmen, the Government are wrong in their premises; and that the expected good effects upon industry and unemployment cannot result from their proposals. (2) That assuming the Government are right in their premises, then the granting of statutory preference and State aid for one competitor as against another is altogether wrong. (3) That if the Government are in error, and the results anticipated by them do not accrue (to the financial detriment of the electricity industry), will increased State aid be allowed by way of relief? (4) That the development of electricity supply in the directions indicated will be a national disadvantage from the point of view of the conservation of our coal resources. (5) That the Government have not considered the whole problem of the national provision of power and heat from the standpoints of the conservation of coal and the national co-ordination of the use of fuel. There are plenty of substantial reasons why the administrators of gas undertakings should strongly support their leaders on the National Gas Council by using every available opportunity, and all influence they possess, to make public the mischievous trend of things through the gravely mistaken policy of the Government. It is true that even now we do not know what is in the Weir report; but the speeches that have been made by responsible members of the Government disclose an intention upon which it is sufficient to act, and that promptly. We are glad to note that already there are indications of somewhat less confidence as to the pro-

priety and soundness of what has been in the minds of the politicians; and there are members of the electrical industry who have been speaking and writing in no uncertain way much along the lines taken by Mr. Milne Watson in his addresses on the subject.

The deliverance by the President at the meeting of the National Gas Council may be taken as supplementary to the one at the meeting of the Society of British Gas Industries. In the latter, as we showed last week, he advanced ample evidence to cause those who are pushing this question of State aid for developing the electricity system of this country to pause (if prudently inclined) and reconsider their position and attitude. But when one takes the two addresses in conjunction, the evidence becomes absolutely overwhelming against the proposals of the Government. If these showed any intrinsic national benefit, there could not be the same degree of objection to them, but, as a matter of fact, they do not. Furthermore, they ignore entirely the services of the gas industry in a country where coal is the prime asset, and in the use of which this industry has been more successful than any other in meeting the needs of the community. In doing this, it has also done more to conserve our valuable coal supplies, and put them to better use, than any other process existing or in prospect. There must therefore be insistence upon full recognition being given to the point so frequently made in our columns, that coal, power, and heat are questions and present problems which are inextricably bound together, and should be considered in their entirety with the whole range of provision and utilization. In this connection, it may be asked, is the cost of obtaining electric power excessive? The answer is "No." Is the cost of obtaining heat by electricity excessive? The answer is "Yes; and it is a most uneconomical proceeding." Yet the Government appear to be unaware of the fact, and so are the public, excepting those who have tried electric heating, and have discarded it save for very occasional and never continuous use. For industrial power purposes, the President points out, electricity here is as cheap as it is in Chicago, and twice as cheap as in Switzerland; and in any case it only represents something like 1½ p.ct. of the total manufacturing costs—indeed, in a representative engineering works of which he knows, power only represents 0·8 p.ct. of the total manufacturing costs.

Resentment is being shown in the electricity industry over the suggestions made by political leaders that the costs of electrical power are too high. We can understand the feeling, in view of the remarkable gap there is between electric power and lighting charges for reasons of expediency. The "Electrical Times" has denied the Prime Minister's statement that the country is "paying too much for its light and power." And as to the effect of power costs on industry, a correspondent of "The Times," who signs himself "B," and is manifestly an electrical man, asserts that while in some industries "the cost of electrical energy is the paramount item, in others it is an appreciable item, but in many industries, if the electricity were given away, it would not make one-half of 1 p.ct. difference in the selling price of the finished product." The same writer asks why the electricity industry has left it to the gas industry to proclaim these elementary truths from the housetops; and he speaks of the danger of the country being stampeded into a vast expenditure of public money for which no case has yet been made out. Again we have Mr. C. Nelson Hefford, the Engineer of the Leeds Corporation Electricity Department, writing to the "Yorkshire Post," urging that an attempt should be made to stimulate public interest in what is developing at Westminster in respect of electricity. He criticizes strongly the false hypotheses upon which the proposals are based. Among several other pertinent points he states that in our large generating stations, whether publicly or privately owned, there is very little margin to-day for any possible saving; and he sees retarding consequences rather than aids to progress in the artificial development of large stations beyond the natural economic demand. Like many other competent men he cannot see whence the wonderful economies are to come. In the President's address at the National Gas Council meeting, there is further evidence as to men in high places in the electricity supply industry viewing the proposals of the Government with anything but enthusiasm—rather with scepticism and dismay.

The points in the address as to the costs of current, consumption per head in comparison with other countries, unemployment, &c., accentuate what was said in the prior address, and demonstrate beyond any contradiction that the Government are following something that is very illusory. So much so that electricians are asking why these matters are not being exposed by the electricity industry, instead of the gas industry. It seems to us (as previously remarked) that the gas industry has taken up a current piece of work—inaugurated so well by Mr. Milne Watson—which is not only in its own protection, but in that of the electricity industry, and the nation at large. But for some inexplicable reason the leaders of the electricity industry appear to be accepting the position lying down, probably regarding the hoped-for State aid as being some compensation for all else not so pleasant that will follow when people awaken to the fact that—presuming the scheme matures—the Government have been misled, and the golden egg turns out to be something wholly fictitious. We hope that all who are interested in these two addresses will read and make use of them as widely as possible, so that the misconception that exists and the truth of the matter may be broadcasted everywhere. This is no time for sitting idle and allowing things to take care of themselves.

Getting and Keeping the Business.

One of the main objects of the District Conferences of the "B.C.G.A." is local publicity. They serve that purpose magnificently in a large radius from the place of meeting. Gas men find they also yield a splendid crop of suggestion and encouragement—no matter whether the individual is engaged in a large or a small concern. This applies to the Minehead and Harrogate conferences, just as it did to those which preceded them. The Minehead Conference was reported a fortnight ago, the Harrogate one in the current issue. As the reports are read, and what they reveal in actual accomplishment is noted—good accomplishment in totally different walks in our industry—we cannot refrain from a little amusement as there comes to mind those of our competitors who examine us through densely coloured glasses or through the wrong end of a telescope, and those political dispensers of favours who appear to be seriously ignorant of the existence and activities of the gas industry, but are of opinion that the electricity industry is in much need of their benefactions. Just consider the mammoth expansion figures given at Minehead by the President of the "B.C.G.A." (Mr. J. H. Elliott, Chairman of the Plymouth and Stonehouse Gas Company), which showed that in statutory areas the output of gas in 1924 increased by 12,272,000,000 c.ft., the number of consumers by 95,897, and cookers and grillers by 316,900. To those increases little Minehead made its contribution as did popular Harrogate, and all the big, medium, and small undertakings of the United Kingdom, despite the frantic efforts of electricity to take from gas part of the domestic load; and, through local influence and not merit, the lighting of streets and public institutions.

Those of our readers who have perused the paper of Mr. Edwin P. Vince, the Manager and Secretary of the Minehead Company, must have been struck and pleased by the high standard of trading policy which that Company prove can be as advantageously adopted by the smaller undertakings as by the larger ones. The Company, with admirable vigour, do their part in the common cause, and apply all things that are beneficial to the business, precisely in the same way as the larger concerns which are progressively directed, with the result that since 1897 they have multiplied their gas sales six times. In that year the consumption of gas was 8 million c.ft.; last year it was 48 millions. Those figures induce one to reflect upon the power, even within limited circumstances, of wise administration. Mr. Vince's paper may be taken as a rebuke to those managements of small concerns who in respect of policy hang back in the shadows of the past. From the statements in the paper, we see nothing more than that is part of the administrative policy of the live of our progressives. And this small Company finds

pays. When we see that 500 houses have been erected in Minehead since the Armistice, and that all of them, except two, have been piped for gas, and the pipes so arranged that gas fires can be fixed in any room, there is as lively satisfaction over the evidence of a go-ahead policy, as there is in learning from Mr. Westlake that, in 95 p.ct. of the houses erected in the dear old city of Exeter in the past four or five years, the extravagant piece of kitchen equipment, the coal range, has not been adopted, but the more efficient, cleanly, non-smoke-producing gas cooker has been installed instead. It must be that our builders and architects are at length being converted to the idea that building economy and modern house efficiency through gas utilization are congenial companions.

To the maintenance of the marvellous purity of the air at Harrogate, we find, from the paper by Mr. Frank H. Robinson, at the conference in the town last Thursday, that gas and coke make excellent contribution. We dare not attempt to imagine what the air of the town would be like if the Company's 11,000 consumers were to return to coal for cooking and heating. We often talk of the good part gas has taken in minimizing the pollution of the atmosphere; but we know there are still nearly 40 million tons of coal used for domestic purposes in this country. The products of combustion from that quantity of coal are a terrible air-polluting affliction; but if it be possible just try to visualize what the conditions would be if the 5½ million gas cookers and grillers did not exist in the British Isles, as well as gas-fires which have never been enumerated. The paper shows the practical unanimity of hotel and boarding-house proprietors in Harrogate in utilizing gas for cooking, coke for central heating, steam-raising, &c., and prepayment metered gas-fires for bedrooms. In the kitchens of establishments where catering on the large scale is carried on, flexibility, cleanliness, reliability, and promptitude are essentials in the appliances used; and gas-heated appliances have all these virtues. As to gas-fires with slot meters attached, the paper shows that the hotel and boarding-house proprietors can get 10 p.ct. on the capital expenditure. In the Harrogate boarding schools and colleges, the equipment is much the same as in the hotels. System is applied in maintaining the good reputation of gas in these large establishments. Before the commencement of the holiday season, the appliances in the hotels and boarding houses are examined, repaired, and adjusted by the Company. Before a term begins at the schools and colleges, the gas apparatus in them is consistently overhauled. At all times, too, fitters are available to keep the appliances working at full efficiency. No charge is made for advice and regulating the appliances; only for repairs, cleaning, and overhauling. And Mr. Robinson finds there is plenty of room for developing service, to the advantage of both the Company and the proprietors of the establishments. The paper contains much suggestive material for those engaged in gas supply in our seaside and inland resorts.

Plant Design and Control.

A MATTER which has large importance in the economy and efficiency of gas plant was introduced in an address by Dr. Geoffrey Weyman to the recent auxiliary meeting of the North of England Gas Managers' Association. This is an age of plant standardization, which is all very well up to a point, but it has the drawback that it does not take into the reckoning variations in local conditions. A standardized plant may, in a situation with local conditions wholly appropriate to it, work splendidly under proper control; but change the conditions, and the same plant may not give nearly such a good account of itself. The address is one which will be considered by both manufacturers and users; and the former will no doubt have a very good case to put up against part of Dr. Weyman's submissions. For example, standardization—instead of the manufacturer having to work to new designs each time—may mean a material saving of capital charges, and also money economy in reconstruction and repairs. On the other hand, the working economies and efficiencies of a specially designed plant to suit local conditions may more than wipe out any additional capital, renewal, or repair charges. It is a controversial point, and one which it is apparent can only be settled by a consideration of the circumstances of each case. We are not going so far as to support Dr. Weyman in his assertion that, when once a plant has been evolved and placed on the market, the manufacturers often lose touch with the small details which contribute so much to successful results. They may do so sometimes; but looking at the history of plant evolution, we have frequently been surprised at the rapid response made by the manufacturers to requirement. Moreover, we have also been aware that the diversity of conditions under which they have to construct plant, and the varied knowledge they gain through contact with different engineers and the recounting of experiences, are frequently the means of bringing about the introduction of improvement. Therefore, we should prefer the "often" in Dr. Weyman's modest indictment to be modified.

Again, it is not always true that the only party really in a position to appreciate the problem and to formulate an economical plant is the user himself. One's point of view is largely guided by experience; and Dr. Weyman views things from the standpoint of one whose professional experience has been in a works staffed by high qualifications. There are engineers and engineers. There are engineers who are assisted by men who know every detail of a works' requirements. The wise chief takes them into his counsel. There are others whose opportunities are not of the same order, and who are not so fortunately placed. Many plants are new to some engineers; and it is an excellent thing for them that the manufacturers can come to their assistance with experience. Dr. Weyman's assertion as to "the only party really in a position to appreciate the problem and to formulate an economical plant is the user himself," cannot apply to such engineers; the best thing for them to do is to recognize that there is another party with knowledge, co-operation in which is valuable. While saying this, there is agreement with the point made that in recent years the education and the training of technical staffs in the gas and other industries has been greatly improved; but, again, it depends on circumstances whether "there is no adequate reason why the design and arrangement of plant should not be systematically considered, and the plant makers be given the necessary plans and specifications which would enable them to put forward plant which is suitable in design and convenient in arrangement for each particular set of circumstances." That requires qualification. "Local conditions" apply to men and knowledge, as well as to situation and raw materials.

But the little difference we have with our Newcastle friend's opinions really only extends to their modification in respect of dissimilar conditions. They are justified in some circumstances, but are not universally applicable. However, there is much else in the address with which there can be absolute concurrence. It may be agreed without reservation that designing a plant best to suit local conditions requires imagination. Its capacity or productive quantity is not the only consideration. One needs to design with a mental picture before him of the conditions under which the plant will be working. Overall efficiency and economy are desiderata. Men cannot work to the highest efficiency unless the conditions for doing so are favourable. There cannot be the satisfactory control that is necessary unless provision is made of accessible positions for the points at which the controlling operations are to be performed—operations involving testing or regulation. Inaccessibility involves labour and time, and engenders a proneness to shirk the work. In designing plant this can be avoided by a little imagination, visualization, or forethought. This has increased importance with the more modern types of plant than with those of earlier days. They have become more intricate, and so has their operation. These facts and the modern conditions of supply make ease of control and accessibility to the point of control real essentials. No one will dispute Dr. Weyman's declaration that if plant is to work with maximum economy, it is necessary to know both when it reaches that desirable level, and the conditions under which this state of affairs can be maintained. Control being imperative to success, it is ridiculous not to consider the provision of the necessary facilities for it at the time the plant is designed, rather than apply them as an afterthought. They are the assurances of

making the money invested in the plant realize the greatest profit. But here again Dr. Weyman says: "It has always been a wonder to me that makers of plant should allow units which they are anxious should be an economic success to be installed without any means whatever of ensuring by proper control that they are so." With that there is agreement. But is it not also a matter for surprise that, if the "only party really in a position to appreciate the problem, and formulate an economical plant is the user," he should allow plants to be erected without facilities for proper control? The user must also be anxious that the type of plant he has recommended shall be an economic success.

There are many other points in the address which will arrest the interest of those whose work is to design plants, or to see that the design is such as to secure and maintain maximum efficiency. The treatment of coal with the view to obtain uniformity of the raw material is one. Dr. Weyman says that there is no doubt a considerable proportion of capital ought to be devoted to this object, as true economy cannot be realized in the retort-house if the coal used is varying from retort to retort and from hour to hour. That must be decided on the basis of the relation of costs to effects. In this connection he also urges, in view of recent investigations, the consideration of the inclusion of blending plant for properly mixing charges with coke breeze or non-caking material. We cannot help thinking that there is much to be done in this way, with the dual object of improving heat transmission through retort charges and enhancing the physical characteristics of coke.

Coke Competition.

June 30 is the last day for the delivery of papers to the Editor of the "Journal." Particulars and conditions were given in the "Journal." for Feb. 18. The prizes total to £1000.

National Gas Council.

In an editorial article, reference is made to the address of the President (Mr. D. Milne Watson) at the meeting of the National Gas Council; but on this occasion the comment is confined to the subject which is raising concern in the minds of a good many men in the country—that is, the intention of the Government in regard to what they apparently believe will secure the development of electricity supply and, through it, the interests of the country. In considering this supremely important matter, sight must not be lost of the vast amount of work which has engaged the attention of the Council during the past year, as revealed by the annual report published last week, and the introductory remarks of the President at the meeting. But great and important as has been that work, it is obvious that the future has in store many more momentous questions which the whole gas industry will have to face in combination through the Council; and there must be no stinting of any necessary expenditure. Otherwise, we shall live to rue the short-sightedness. On March 31 last, there were 841 undertakings subscribing to the funds of the Council, representing 88 p.ct. of the total make of gas in the United Kingdom. Where are the undertakings comprised in the 12 p.ct.? Are they not enjoying the fruits of the work done voluntarily, and the expenses attaching to which are paid by the 841 undertakings? Surveying modern and prospective conditions, there is certainty that the fullest unity is essential. The very position and progress of the industry attract people—some to see what they can get out of it, others moved by envious motives, others again who seek to put before it new barriers and upon it new obligations. There is no question the National Gas Council will have to be maintained in existence and in the highest state of efficiency and power—always. To part with it (no one fortunately dreams of doing so) would be to cut out from the industry a vital part.

"Field's Analysis."

On a later page will be found a review of the 1924 edition of "Field's Analysis," which has just been published. Attention is drawn to some of the notable figures contained in the work; particularly interesting being the reference to the working of the Gas Light and Coke Company for the past year. The "Analysis," under the guiding hand of its compiler, Mr. H. E. Ibbs, Chief Accountant of the Gas Light and Coke Company, will be found to maintain fully the high standard of efficiency which is always associated with this publication.

Mains of Insufficient Capacity.

At length, a clause has been agreed between the railway companies and the National Gas Council to supersede the one which previously had existence with regard to relief to gas undertakings from the obligation to supply gas where mains are of insufficient capacity. In future, gas undertakings should be able to obtain the insertion of this clause in their Private Bills or Special Orders. The negotiations over the clause have given much trouble and absorbed much time; but the issue appears to give full protection to gas undertakings who may require it, while satisfying the railway companies, which has not been an easy matter. The clause appears *in extenso* in our "Parliamentary Intelligence" under the heading of "Mansfield Corporation Bill."

All-Electric Houses.

We should like the attention of the Rochdale Town Council called to the article which appeared in the "Journal" for May 13 (p. 444) under the heading "Municipal Prohibition of Gas." They will see in it that Parliament does not approve of municipal authorities removing from tenants of houses their right to use whichever forms of lighting, heating, and cooking they prefer. It appears that the Gas and Electricity Committee of the Rochdale Council have decided to adopt a new policy in Corporation houses. According to the "Rochdale Observer," they have hitherto provided a dual service of gas and electricity. Now in sixty-six new dwellings on what is known as the Kilworth Street site, they have decided that electric fittings only shall be installed. The houses will have coal-heated ovens; but the choice is to be between these and electric stoves. We hope the Council will have a greater consideration for domestic economy and the liberties of the tenants than the Committee have shown by their autocratic resolution. Also that they will consider the bearing of the Newport decision to which reference is made in the opening lines of this paragraph.

Domestic Coal Prices.

Through untoward circumstances, the price of gas has ascended; but fortunately this is the period of lightest consumption. The London coal merchants are now making strong efforts to secure the custom of householders. In Central London the "lowest summer coal prices" came into operation last Saturday. From the quotations we see that Derby brights show a reduction of 3s. 6d. per ton on 1924, and 1s. on 1923, whereas kitchen nuts are no less than 6s. cheaper than in 1924, and 5s. cheaper than in 1923. "Best coal" is now quoted at 50s., as against 56s.; best silkstone, 44s. 6d., against 48s.; Derby brights, 45s., against 48s. 6d.; and so on until we come to kitchen nuts at 30s., against 42s.; and stove coal 32s., against 38s. 6d.

How to Save Money.

At their conference at Brighton last week, the Royal Institute of Public Health had the question of the uneconomy of coal smoke brought before them in a paper by Dr. Charles S. Thomson, the Medical Officer of Health for Deptford. He asserts that of the 100 million tons of coal used in this country for industrial purposes, 43 millions are wasted—a record which he is certain must bring a smile to the faces of the very efficient Germans. If manufacturers would only take steps to provide heat without wasting so much by the crude use of coal, they would not need to tremble over their contributions under the new insurance scheme. That is the view of Dr. Thomson.

Electrical Humour.—During the recent heavy floods at Batley the following letter was received at the Gas Office from an electrical engineer: "Dear Sir,—Will you kindly let some one attend to the gas supply at the above address? It seems to be adopting an electrical tendency—being of an alternating nature, with a periodicity of about 1 per sec."

DIPLOMA WINNERS.

In the Institution Gas Engineering Examination.

We have received from the Organizing Secretary of the Education Scheme of the Institution of Gas Engineers (Mr. Walter Hole) a list of the successful candidates at the recent examination for the Institution Diploma in Gas Engineering. The certificates will be presented by the President (Mr. J. Ferguson Bell, M.Inst.C.E.) at the first session of the annual meeting.

First Class.

Name.	Address.	Subject of Thesis.
RATER, THOMAS HAROLD	London . .	Coal Gas Condensation.

Second Class.

MITH, SYDNEY	Birkenhead .	The Manufacture of Sulphate of Ammonia.
LAKE, THOMAS VINCENT	Cardiff . . .	The Volatile Products of Coal with Continuous Vertical Retorts.
IELVIN, DUNCAN DEWAR	Glasgow . .	The St. Mungo Washer-Scrubber.
YSON, THOMAS . . .	Longwood . .	The Construction and Working of the Dempster-Toogood System of Vertical Retorts.
ATEMAN, CHARLES . .	Cardiff . . .	The Neutralization of Sulphate of Ammonia.

There were no candidates for the Diploma in Gas Supply his year.

The results in the Ordinary and Higher Grades will be published in due course not only of the Engineering and Supply Examinations, but of those in the ancillary subjects.

PERSONAL.

Mr. A. H. Besche, who for many years was Sales Director of Messrs. Kerr Stewart & Co., Ltd., of London and Stoke-on-Trent, has been appointed General Sales Manager of Messrs. & F. Howard, Ltd., of Bedford.

Mr. S. Barker Johnson, the Engineer and Manager of the Colombo (Ceylon) Gas and Water Company, Ltd., has arrived in England on furlough. He travelled from Ceylon on the "Ormuz," and reached London on May 29. The London Offices of the Company are at No. 148, Gresham House, Old Broad Street, E.C.

The Colne (Lancs.) Town Council have adopted a recommendation of the Gas Committee that an honorarium of £100 be granted to Mr. H. Thorpe, the Gas Engineer, in respect of special professional services rendered by him in connection with the installation of new plant and the re-modelling of the gas-works. The Chairman of the Gas Committee (Alderman Keighley), replying to an amendment, said Mr. Thorpe had been doing a lot of special work during the last five years. He had got them out of a difficulty, and by adopting his advice the Council had saved between £30,000 and £40,000. Only six voted for the amendment.

OBITUARY.

We are sorry to learn of the death at Bristol, on the 21st ult., of Mr. Robert A. Browning. He underwent an operation early last month, which was satisfactory; but unhappily complications subsequently set in. Mr. Browning resigned in 1915 from the position of Engineer and Manager at the Neath Gas-Works, after having been in the service of the Corporation for 44 years, and was appointed Consulting Engineer for a period of three years. He will be greatly missed from the meetings of the Wales and Monmouthshire District Institution of Gas Engineers and Managers, whose second President he was. The Institution was formed in the autumn of 1905; and Mr. Browning followed the late Alderman Thomas Canning, of Newport, in the chair in 1906—the Institution holding a meeting at Neath during his year of office.

Industrial Gas Salesmen's Circle.

The next meeting of the Circle will be held at the Council House, Birmingham, on Friday, June 19. Members will assemble at ten o'clock. During the morning inspection will be made of the industrial gas demonstration rooms and research laboratories of the Birmingham Gas Department, and visits will be paid to the Windsor Street heat treatment shops, and to the works of the Moss Gear Company, Ltd. At one o'clock luncheon will be held in the Imperial Hotel. During the afternoon brief statements, accompanied by drawings or diagrams, on the following subjects will be presented for discussion: "Some Uses of Gas in Printing Works;" "The Application of Gas to Ship Repairing;" "Large Pipe Bending;" and "Gas and Other Fuels for Power Purposes."

ELECTRICITY SUPPLY MEMORANDA

We are not sure whether the "Electrical Review" intends to be humorous or whether it is a little off the path of truth, when noticing a new scheme for enlarging the finances of the Electrical Development Association. If what it says is true, then the inference is that a large part of the administrators of the electricity supply industry are very foolish and apathetic. It states that men in the various branches of the industry are so imbued with the "electrical idea" that they cannot conceive that the backwardness of the people is anything more than sheer apathy. In the same vein, it proceeds: "They think that, if electricity cannot sell itself on its merits alone, there is nothing more to be done. Accordingly, they go on advertising their individual products merely hoping to attract the attention of those who are already converted to electrical methods, while suppliers of electricity wait for the would-be consumer to call at the office for a list of charges." It is admitted that "there are many honourable exceptions, but they must be exceptions, or Great Britain would be using as much electricity per head as (say) the United States." Is it true that that is the unbusinesslike way electricity trading is carried on? We cannot believe that advertisers of electrical wares merely hope to attract the attention of those who are already converted to electrical methods; their idea in advertising is to attract those who are not already converted, and to keep prominently before purchasers the virtues of their own particular productions. Nor are we inclined to think that electricity suppliers sit in their office armchairs waiting for the would-be consumer to turn up, and ask for a list of the charges. If that is a correct representation of the position, then it is time that the laggard administrators were sent about their business, and enterprising business men appointed in their stead. It also suggests another thing, that the Electrical Development Association have not succeeded in rousing these inert maladministrators to see the errors of their sleepy ways, or have not by their work impressed upon a large proportion of managements the indispensability of the organization, and the effectiveness of its work. Instead of asking for money to educate the public, they should first request a goodly fund for the purpose of educating managements to better business methods, and then the future of the Association would be assured and fully provided for. Of course, it is a far cry for this country to realize a consumption of electricity per head equal to that of the United States. Conditions here and there are not wholly similar; and there are sufficient reasons for the difference which now exists.

Sleepy Administrators.

Then our dear friend the "Review" indulges in a little illogical musing. First of all it says that electricity will not sell itself any more than any other commodities which are not positively essential—and this despite those electrical men who rave about the super-merits of the electrical way of doing things, which is not endorsed by the major preference of the public being for gas, with its greater value for money expended. It asserts with truth that "it is futile to say that electricity is essential to the individual." But this is followed by the vain boasting which is inseparable from the electrical mind, and which has done some amount of good among the people by causing them to look with suspicion upon those who claim everything good for their commodity and acknowledge no defects, which have become as well known to the public as the meretricious prating regarding merit. Says the "Review," "that electricity will ultimately supersede every other form of energy, we are convinced; and we therefore conceive it to be the duty of all who desire the advancement of the race to hasten that consummation." That is wonderful. The mere statement of a personal conviction is not proof that the predicted will happen. The grounds of the conviction are more important, and knowledge of them would be more interesting than the mere unsupported conviction of the "Electrical Review." When the great gas industry is put to death—a prospect which we contemplate with marvellous equanimity—by the appropriation by electricity of the whole of its business, "electricity will," remarks our sagacious contemporary, "then be really essential, for its competitors will have fallen out of use." That is perfectly obvious. If there is only one means of providing light, heat, and power, then that means would be "essential." Perhaps our contemporary can give us some intimation as to the distance of time covered by the term "ultimately," because we see no present or prospective signs of gas falling out of use. As a matter of fact, its position is being strengthened daily. It is neither good logic nor is it practical to talk as the "Review" does in this connection. If gas as a competitor is to be superseded, then as a preliminary electricity has to realize treble or quadruple its present efficiency in the utilization of coal. In this relation, we should like our contemporary to tell us what is to happen to the carbonization of coal, which is "fundamental in the part it plays in modern

On Being Essential.

civilization" and in the work of the world; the products being highly essential to our industries. Being so, gas must be produced; and as gas is produced with a greater efficiency than electricity, more potential heat energy is, for a given sum, placed at the disposal of the individual through it than through electricity. If the latter is only to become "really essential" by the death of its competitors, then it will have to wait a very long time.

More Propaganda Revenue Wanted.

If what our contemporary says is the sort of thing that is considered to be necessary to construct a case for a larger revenue for the Electrical Development Association, we are afraid it will not assist much among intelligent men. However, we get to a more serious plea for support of the work of the Association. What is wanted, it is stated, is education of the public. "The public," it is said, "is not apathetic when it is shown where its best interests lie; and it is the work of the electricity industry to do this." What has the Development Association been doing during the years of existence if it has not been educating the public? If the organization has been performing its functions efficiently, it has been "educating" the public from the electrical point of view; but apparently the public are not convinced that their "best interests lie" in the adoption of electricity for cooking and room and water heating. We admire the sagacity of the public. Our contemporary, however, thinks that "within the rigid limits imposed by inadequate funds, the E.D.A. has accomplished a great deal; but none of its effective slogans is yet a household word." We are not astonished. Now the Association assert that the industry is not giving it enough money to make the work as effective as it should be. The result is spasmodic efforts instead of a sustained campaign. Therefore a brochure has been prepared which has been addressed to the members of committees, boards, and managers of all electricity supply undertakings in Great Britain. In this the activities of the Association are described; and care is taken to show how small a proportion of the revenue of electricity supply undertakings is devoted to the important work of educational propaganda. The request is made to the responsible persons addressed to arrange that 0·1 p.ct. of the revenue of their undertakings is contributed to the funds of the Association. It is stated that the manufacturers and other associations have agreed to increase their subscriptions if the suppliers will respond to the appeal. It is confidently anticipated that the proposals for future activities will result in assuring the Association a revenue sufficient for their growing internal work, and in addition for direct educational efforts, to the value of from £20,000 to £25,000 per annum.

The Enlarged Campaign.

The main objectives of the enlarged campaign which the Association hope to be able to carry out if entrusted with greater disbursement power are described as follows: To build up national and industrial goodwill; to remove unwarranted bias and criticism; to establish and maintain public confidence; to encourage local inquiries for electrical information and advice; to create demand; to obtain increased revenue from the fixed charges of electricity supply undertakings; to reduce the cost of supply to consumers; and to increase the revenue and profits of suppliers. Regarding this programme our contemporary remarks: "Nothing is said of the direct benefits to manufacturers and contractors; but these are, of course, sufficiently obvious. Such a programme should loosen the purse strings of the most sceptical or conservative committee or board."

A Queer Reply.

Viâ the Editors of the "Electrical Review" (whom we thank for their courtesy), we have had forwarded a letter from Mr. E. G. Ross, which purports to be a reply to our criticism (see "Memoranda" for May 20) of an article of his which appeared in our contemporary. Of all the disjointed, ineffective effusions that has ever reached us from any source, this one, we truly believe, easily takes precedence. There is not a point in it which in any way alters our criticism and expressions of opinion based on experience and testing (scientific and practical) which were published upon his laboured and fruitless work—fruitless because the analyzed heat losses on gas and electric hotplates (the data being derived in his case by methods which were confessedly crude, and therefore unreliable) are easily ascertained in the total by doing the same amount of water boiling, noting the input of thermal energy while the work is being done, and discontinuing when the water reaches boiling-point. There is for making comparison more definiteness and reliability in this procedure than in that of Mr. Ross. Several of the comments of our correspondent are really too absurd to deal with seriously. But reference may be made to three or four points. Mr. Ross makes a distinct departure from the truth when he says: "I am indebted for the suggestion that *it is essential* to keep on full heat for four hours to keep the pot contents boiling." Nowhere in our criticism did such a stupid idea as that appear; nowhere did we say that such a thing was "essential." As to the loss of heat when boiling, he says that a "minimum" of 30 p.ct. is not contradicted by us. We would ask Mr. Ross to read again what he said in his article: "From data variously collected, it would seem that when boiling for approximately four hours in a pot about 5½ in. diameter, anything from a minimum of 30 p.ct. to a maximum of 60 p.ct. of the available gas heat is lost, due to these essential conditions of burning." This is what we said: "The minimum of 30 p.ct. is nearer *normal* practice to-day than the maximum of 60 p.ct. As a matter of fact, the modern boiling-ring on the hotplate of a gas cooker is quite capable of developing 70 p.ct. efficiency." Cannot he see in this that we did not agree with his minimum *per se*, but accepted it as being about "normal." There is a wide difference between a minimum of 30 and a maximum of 60 p.ct. It is observed that Mr. Ross carefully abstains from replying to our inquiry as to whether he can suggest to us any electric boiling-plate which will at any part of its life and continuously give an efficiency of 70 p.ct.; and he ignores the question: Is it not the fact that most electric hotplates will only develop (when new) 40 to 45 p.ct. efficiency, and that a diminishing quantity with use?

Ribs and Costs.

As to the old-fashioned ribs which assist to dissipate heat by conduction from the hotplate of gas-cookers, we mentioned that the gas industry found this out long ago. Mr. Ross asks then why were the ribs not cleared out "long ago;" and further he wishes to know just what proportion of all the cookers installed in this country do the "modern cookers" made within the last few years represent. On Mr. Ross's notepaper, we see his description is "Electrical and Mechanical Engineer." As such we should have imagined he would know that it is no light task to take out a few million gas-cookers and reconstruct the hotplates. We have to be sensible in dealing with such matters. What is being done by many gas undertakings is, as cookers come in for renovation and repair, to remove the old hotplates and incorporate one of the high efficiency types. This, an engineer will agree, is a rational proceeding. Goodness knows how many "modern" cookers have been installed in this country the last few years; but the makers have been busy turning them out, and not for the mere fun of the thing. They have also been making the new types of efficiency hotplates for replacement purposes; and a good business it is. Mr. Ross gives his expenses for gas cooking (including boiler) over a period of eight months as £5 16s.; and electricity (light and iron), flat rate, as £3 8s.—together £9 4s. We do not know what the respective charges were, or the amount of work done. But in a corresponding electric-cooker period, the total costs on the two-part tariff (including 13s. 4d. hire charge, and 7s. 10d. for gas for boiler) was £7 7s. 11d. No information is given as to the fixed charge and the charge per unit, nor as to the work done. All that is said is "for the same conditions of living." As they stand, the figures do not prove anything." In connection with them, we will repeat the last five lines of our previous comment: "After all this, will Mr. Ross accept a challenge to do an equal amount of work with an electric cooker (oven and hotplate) as with a gas cooker, at a cost for 'fuel' of ¾d. per unit for electricity and 10d. per therm for gas, or 3420 B.Th.U. as against 7500 B.Th.U. for ¾d. in each case?" He has omitted to reply to this. We will guarantee adequate publicity for the results of the test.

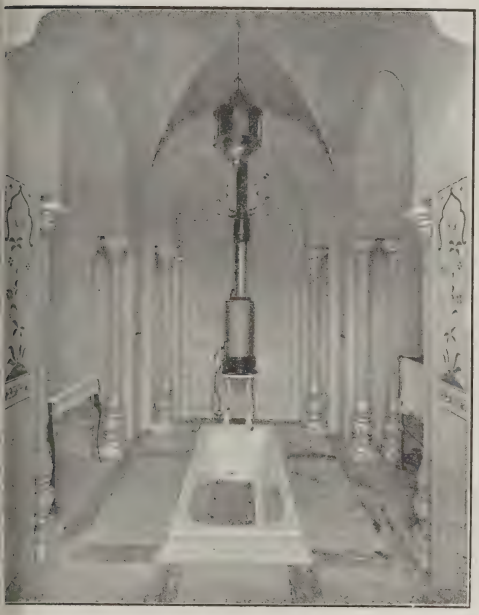
"Safety" of Electricity.

In the "Memoranda" last week, reference was made to a fire which occurred at the Royal Sussex County Hospital at Brighton, and which again illustrated the danger of installing electric wires in close proximity to gas-pipes. In that case the fusing of an electric wire melted the gas-pipe, and ignition followed. Since then, there has been a fire at Doncaster at a piano shop and warehouse in Hall Gate, which was also due to the fusing of two electric wires. The heat from the fused wires melted a gas-pipe, and precisely the same thing happened. The gas escaped, was ignited, and the floor boards caught fire. These illustrations should be a warning to those who wire houses in which gas pipes are already located. Recently James Hannon received a fatal shock while working at the Orgreave Colliery Coke Ovens, near Sheffield. It seems that the man leaned over a handrail in order to loosen some coke; and in doing this he caught, with a hooked iron bar he was handling, an overhead trolley wire at 275 volts. The ground he was standing on was very conductive, being composed of damp coke breeze. A verdict of "Accidental death" was returned. We also see that three men were severely burned at the Hull Corporation Electricity Station last Saturday week. Additions were being made to a 6000-volt switchboard gear, when there was a severe short circuit, which had the effect of temporarily disconnecting the main turbines. There was an explosion, and a tremendous flash of flame. In addition to injuring the men to such an extent that two of them had to be detained in hospital, the supply of electricity was temporarily cut-off from one district.

"The Conversion of Coals into Oils."—This book, by Dr. Franz Fischer, has been translated by Dr. R. Lessing, and is now published by Messrs. Ernest Benn, Ltd., at 36s. net.

THE GAS EXHIBIT.

SUPPLEMENTARY VIEWS.



The Bathroom, with Gas Water-Heater
Supplying both bath and hand basin with hot water, in the "Indian" Section of the Gas Exhibit.

Ice-Making and Refrigerating Plant in the "Indian" Section of the Gas Exhibit.
This is operated without machinery. Heating only over a gas-ring results in the production of small blocks of ice convenient for use in drinks as well as for cold storage purposes.

POTTERY-MAKING BY THE DISABLED EX-SERVICE MEN EMPLOYED BY THE ASHTEAD POTTERY
The pottery is baked in the gas-fired oven to be seen on the left.

BENZOLE RESEARCH.

Second Report of the Joint Benzole Research Committee.

The Second Report of the Benzole Research Committee of the National Benzole Association and the University of Leeds deals in detail with the corrosion test for benzole and other motor spirits, with laboratory experiments on various kinds of active carbon and silica gel, and with visits to working plants where benzole is being recovered by the new method of adsorption.

The account of the research work of Mr. W. H. Hoffert bears ample evidence to indicate that he is a worthy successor to Prof. E. C. Williams as Research Chemist to the Committee.

Sulphur in Benzole.—Certain benzole motor spirits, though free from sulphuretted hydrogen and containing not more than the 0·4 p.ct. of sulphur allowed by the National Benzole Association specification, having been proved to have a marked corrosive action on copper, were subjected to careful examination. Such benzoles cause trouble in motor engines by attacking copper and brass parts such as floats, gauzes, feed tubes, &c., forming black deposits which flake-off and lead to choking of gauzes and jets and to vexatious renewals of corroded parts. The corrosive deposit was found to consist of cuprous and cupric sulphides. It was discovered that certain benzoles of a corrosive nature contained appreciable quantities of free sulphur; and this led to an investigation of the action on copper of solutions of sulphur in benzole of known source and purity. It is interesting to note that—as was established by these investigations—the presence of certain impurities in the benzole tends to inhibit or prevent corrosion of the copper, and that the concentration of free sulphur required to cause corrosion depends on the nature and amount of such impurities. In carrying out these tests, preliminary treatment of the copper surface was found to have a marked influence on the corrosive effect; the most sensitive surface being obtained by mechanical polishing, rather than by chemical cleaning.

After an examination of the published methods of determining free sulphur in benzole, a modification of the method of Ormandy and Craven was adopted. Briefly, the modified test consists in removing the sulphur from the benzole as mercuric sulphide by shaking with mercury, then treating the sulphide with concentrated hydrochloric acid and absorbing the sulphuretted hydrogen thus evolved in an ammoniacal solution of cadmium acetate. Excess of iodine is added, and the back titre obtained with thiosulphate.

Consideration is given in the report to the "doctor" test commonly used in America for the detection of objectionable sulphur compounds in petroleum fractions. This consists in shaking the sample with sodium plumbite solution and free sulphur. If the sample is discoloured, or if the yellow colour of the sulphur film is noticeably masked, the test is reported as positive, and the sample is condemned. After giving results of experiments on the action on copper of organic sulphur compounds in benzole, and data of other investigations, including explanations of the formation of free sulphur, this section of the report concludes without definitely recommending a specification test for determining the corrosive action of a sample of benzole, seeing that the work is still proceeding.

Active Carbon v. Silica Gel.

The second section of the report deals with tests comparing active carbon and silica gel as adsorbents. The samples of active carbon examined were:

1. German active carbon (Bayer T Kohle).
2. American coconut charcoal of high retentivity.
3. Urbain active carbon or coal ("charbon actif").

The respective quantities of benzole taken up by these carbons and by silica gel when saturated at 20° C. with a benzole-air mixture containing 0·86 p.ct. by volume of benzole vapour (the amount ordinarily present in coal gas) were as follows, expressed as percentage weights of adsorbent: Urbain carbon, 36; coconut charcoal, 32; Bayer T carbon, 28; and silica gel, 18. In spite of these differences, the efficiencies of adsorption were practically the same in each case—about 98 p.ct.; twice as much gel, by weight, being required to extract the same amount of benzole as with Urbain carbon.

The influence of temperature on the adsorptive capacities, at saturation, of the T carbon and silica gel was the next subject for investigation. The decrease in adsorptive capacity occurring with a given rise in temperature was found to be much less than is the case with wash oils.

Experiments carried out on the influence of aqueous vapour on the adsorption of benzole proved that silica gel adsorbs the water vapour and removes it quantitatively from the air mixture, but nevertheless shows a fairly high adsorptive capacity for benzole under recovery conditions. It may seem surprising that the gel takes up benzole at all, since the vapour is present at considerably lower partial pressure than the aqueous vapour. That the gel at first takes up more benzole than water arises from the fact that, though the volume of water vapour present in the gas mixture is two to three times that of the benzole vapour, a given volume of benzole vapour yields 4·33 times as much liquid by weight as an equal volume of water vapour. The benzole thus fills up the pore space before sufficient water reaches the gel.

Active carbon, on the other hand, preferentially adsorbs the benzole, and the presence of water vapour does not affect the efficiency up to the break-point. The adsorptive capacity at the break-point and at saturation is, however, slightly reduced; the respective percentage weights for a sample of active carbon being 20·3 and 22·5, instead of 26·0 and 28·0 in the absence of water vapour.

In comparing Bayer T carbon, which has low retentivity, with coconut charcoal, which has high retentivity, no appreciable difference in efficiency of adsorption was observed. The difficulty experienced in removing the adsorbed benzole from the latter is regarded as significant from the point of view of steam consumption on the commercial scale, and possible "poisoning" of the carbon by high-boiling substances.

It was concluded from the results obtained by Hoffert, and those already given in the first report, that for a gas containing 0·86 p.ct. by volume of benzole vapour (2½ gallons per 12,000 c.ft.) and saturated with water vapour at 18° C.—that is, under conditions corresponding approximately with those of large-scale practice—the maximum quantities of benzole taken up at saturation by active carbon and silica gel would be as follows:

	Grammes Benzole Adsorbed per 100 Grammes Adsorbent.	Grammes Benzole Adsorbed per 100 c.c. of Adsorbent Space (material, 5—8 mesh).
Active carbon	15 to 30	5·8 to 11·6
Silica gel.	8 to 14	5·7 to 10·0

Thus, though the active carbon shows a considerably higher adsorptive capacity for benzole than does silica gel under benzole-recovery conditions as calculated on the *weight* of the adsorbent, the quantities taken up by these adsorbents as calculated for a given *volume* are very nearly the same, owing to the greater density of the gel.

As Urbain had stated that his experiments on silica gel did not agree with those of Williams (First Report, 1924), and Chaney found silica gel to be valueless in presence of moisture the investigations in question were repeated by Hoffert, who confirmed the results of Williams. In Hoffert's test, with an air mixture containing 0·88 p.ct. of benzole and 2·05 p.ct. of water by volume, silica gel took up 11·6 p.ct. by weight of benzole and 6·2 p.ct. by weight of water at the break-point. On continuing the test beyond the break-point, the benzole left in the gel after 2000 minutes dropped to 0·4 p.ct. by weight.

The effects of variation of temperature on the recovery of benzole from a benzole dry-air mixture by active carbon, silica gel, and creosote are compared in an interesting way; the result being as follows:

Percentage Reduction in Quantity of Benzole taken up at 15° C. caused by Increase in Temperature.

Active Carbon.	Silica Gel.	Creosote.
1·2*t* ..	1·38*t* ..	2·74 (Bunte and Frei) 3·7 (Rhead)

where *t* = number of degrees above 15° C.

Thus, by increasing the temperature from 15° to 35° C the adsorptive capacity of active carbon is reduced 24 p.ct silica gel 28 p.ct., and creosote over 55 p.ct.

When water vapour was present, the factor for silica gel was found to be 1·5 *t*—not very different from the foregoing.

It was found that in the case of active carbon, provided that the temperature of adsorption is 10° to 15° C. higher than the temperature at which the air is saturated with water vapour the presence of the latter has practically no influence on adsorption.

Active Carbon Plants.

The remainder of the book of 246 pages is devoted mainly to reports on active carbon plants, and on the quality of the benzole made by these.

The Bayer plant at Leverküsen, near Cologne, was working on purified town gas, and was dealing with up to 70,000 c.ft. of gas per 24 hours, obtained from Ruhr coal of poor quality. Two filters, each containing 5½ cwt. of T carbon to a depth of about 40 in., worked in series, and were preceded by a prefilter which held 2 cwt. of cheap B carbon for removing naphthaler. The contents of the prefilter required renewal every eight weeks, and the naphthalene was driven-off, and the carbon reactivated by carbonization at 600° to 900° C.

The gas, after leaving the prefilter, passed through the two filters in series, and travelled downwards through the active carbon layer, as it was found that the "pulsing" which occurred when the gas flowed upwards caused powdering of the material. When the first filter became saturated, it was cut out of the system, and closed steam at about 70 lbs. pressure was turned on, passing through concentric coils in the filter. As soon as the whole filter reached 100° C., open steam of a similar pressure to the above was allowed to expand directly into the top of the filter, and was turned off when no more benzole flowed from the condenser.

After steaming, the filter was put into operation again at once; the debenzolized gas from the filter still in operation being used to cool and dry the steamed carbon—the cooling of the latter being rapid, owing to loss of heat by evaporation of the water remaining in the carbon. In this way each filter was

ccessively saturated, steamed-out, and put on in series after e other, which had meanwhile been working alone. The eam consumption was said to be about 3 lbs. per lb. of benzole covered; but a trial run gave a higher figure.

When the plant was inspected, the active carbon in the filters d been in use for six months, during which time 3 to 4 tons benzole had been obtained. There was no evidence that the sorptive power of the carbon had decreased appreciably during at time. The benzole recovered was light yellow in colour, ntained 0·5 to 0·9 p.ct. of sulphur (chiefly as carbon bisul- ide), and distilled 95 p.ct. to 140° C. There was apparently specification in Germany for benzole used as motor spirit, d the benzole was used as recovered in motor cars, and on a H.P. "Mercedes" test bench motor, in which no trouble had far been experienced.

A plant on similar lines to the above had been erected at ils, near Recklinghausen, for the extraction of benzole from purified coke-oven gas, but had not been put into operation, ring to political and economic difficulties in the Ruhr. rangements had been made for the gas from a battery of 60 to coke ovens to be sent either to the scrubbers for the re- oval of benzole by oil-washing, or to the newly-erected plant recovery of both sulphur and benzole by means of active bon. The scheme is as follows: The gas, 3½ million c.ft. day, first passes through the filters for sulphur recovery, d then through the benzole filters. In the former sufficient ygen (1 p.ct.) is added to the gas to promote the reaction $H_2S + O_2 = 2\,H_2O + 2\,S + 111$ calories, which takes place the presence of active carbon. A little ammonia is added to as catalyst. A special form of active carbon (F carbon) is ade from lignite by the Bayer Company for this process, and reaction proceeds at the ordinary temperature. Three phur filters are installed. At any time one filter can be used the removal of sulphuretted hydrogen, a second filter can be racted with a solvent to remove the sulphur from the active bon, and the third can be steamed-out, and dried by the gas ning from the first filter. The solvent preferred is am- nium sulphide, and each filter in turn is filled with a solution this chemical, as it is found that mere percolation through carbon does not dissolve the sulphur. If removal of the phur is found to be incomplete, arrangements are made for a al wash with monochlorbenzene. The ammonium polysul- ide obtained is decomposed by steam, with precipitation of phur, which is filtered and centrifuged; and the ammonium phide is used over and over again. The benzole filters are bstantially of the same design as those at Leverküsen.

A benzole plant working with active charcoal on purified gas Bernau Gas-Works, Germany, is also described. This had n in operation for three months at the time of the visit. A phthalene prefilter was not used; and superheated steam at 0° C. was employed for stripping the benzole. The latter was y faintly coloured, contained 0·5 p.ct. of sulphur, and dis- ed 90 to 95 p.ct. up to 120° C. It was claimed that it worked fectly as a motor fuel, and caused no formation of carbon or n in the engine. About 3·4 lbs. of steam per lb. of benzole re necessary for stripping the benzolized carbon; but to this ire must be added an allowance for superheating. No loss efficiency of the carbon had so far been observed.

The Bayer Company are credited with making the following erent kinds of active carbon:

. H, ordinary. Made from wood. Sp. gr. 0·25.
. T. Made from peat. Sp. gr. 0·4. Improved form for benzole, &c.
. B. Cheap form for naphthalene and "tar-fog." Sp. gr. 0·6 to 0·7.
. F. Made from lignite. Sp. gr. 0·3. For removal of sulphuretted hydrogen.
. E. Decolorizing carbon. Screenings from the other types.

The Grenoble plant, in which Urbain active carbon was being d, was inspected, and is described in the report. Dr. Urbain med to have produced a carbon superior to the Bayer pro- t; and at the plant installed at the Grenoble Gas-Works e filters were in operation at the time of the visit—two filled h Bayer T carbon (880 lbs. in each), and one with Urbain bon (770 lbs.). The filters worked in parallel, and there was prefilter for naphthalene removal. The gas treated was ified in the usual way with oxide; and a volume of about ,000 c.ft. per day was being debenzolized. In normal opera- two filters were adsorbing in parallel while the third was ng steamed. Each filter operated on a 12-hour cycle; the orption period being 8 hours. They had been in com- sion for 2½ months (about a year ago).

The method of removing the adsorbed benzole was by first ting the carbon to 100° C. by means of an internal steam for 30 to 40 minutes with steam at 70 lbs., and then passing erheated steam at 7 lbs. and 250° C. directly into the top of filter for half-an-hour. After driving-off the benzole, the r was dried by heating the carbon by means of the internal im coil while gas was passing through. The average steam sumption was 2½ to 3 lbs. per lb. of benzole; but a ratio of 1 was claimed under optimum conditions. At the maxi- m gas speed for which the filters were designed (175 c.ft. per ute per filter) the loss in gas pressure was 1½ to 1¾ in. of er; and in this respect at any rate the Urbain filter was inctly better than those filled with Bayer carbon. The re- cords of the plant appeared to substantiate the claims that the Urbain carbon was also slightly superior to the Bayer product in rate of adsorption and in capacity, as well as in resistance to disintegration.

The quality of the benzole obtained was very good. It was practically water-white, and the evidence would seem to indicate that benzole of better appearance is obtained when superheated steam is used instead of saturated steam for stripping the carbon. The sulphur content was 0·57 p.ct. by weight; more than half of this being in the form of carbon bisulphide. Distillation of the benzole yielded 94 p.ct. at 125° C.; and a copper dish test gave only a small quantity (0·017 gramme per 100 c.c.) of brown resin.

As regards the possible use as motor spirit in this country of unrefined benzole recovered direct from coal gas by means of active carbon, some doubt is expressed as to whether such motor spirit would be acceptable, or would pass the present specification tests. So far, on the Continent, only limited supplies of carbon-recovered motor benzoles have been available, and these have been used as soon as recovered, before any appreciable polymerization of the gum or resin forming constituents could be expected to take place.

The book concludes with a very full bibliography (21 pages), for 1923 and 1924, of literature relevant to the production and purification of benzole.

As we know that active carbons and silica gels (see "Petroleum Times," April 18, 1925, p. 728) are being improved rapidly, there must be plenty of work before the Benzole Research Committee; and we look forward with great interest to the publication of further valuable investigations.

EVENING STAR LODGE, No. 1719.

On Wednesday evening last the regular meeting of the Evening Star Lodge, which is always held on the fourth Wednesday of the month of May, took place. W. Bro. Hermann L. Sheppard was in the W.M. chair; that of the S.W. being occupied by Bro. A. H. Henry, and that of the J.W. by Bro. Frederick G. Cockey.

First, W. Bro. E. G. Smithard, of King's Lynn, P.M., P.P.G. Treas., Norfolk, was installed as Treasurer of the Lodge for the year 1925-26, he having been prevented from attending the last meeting, when the appointment and installation of the other officers was carried out.

Three candidates for initiation were then ballotted for; and the W.M. declared each of them unanimously elected. They were: Mr. Wilfred Baker Claridge, Manager, Engineer, and Secretary of the Marlborough Gas Company, Wilts; Mr. James Waldron Swan, Assistant Manager and Secretary of the Hitchin Gas Company, Herts; and Mr. Leslie Walter Dunn, Engineer-in-Charge at the Linacre Works of the Liverpool Gas Company, Bootle, on new constructional work.

The initiation of Mr. Claridge was then carried through by the W.M., W. Bro. Valon, P.M., L.R., assisting; the office of J.D. being discharged by W. Bro. James Foreman, and that of S.D. by W. Bro. A. L. Croager.

Reference was made to the Emergency Meeting of the Lodge, which is to take place in the Grand Temple of Freemasons' Hall on Monday, June 8, when about two hundred masonic members of the Institution of Gas Engineers are expected as guests, on the eve of the opening of the Institution's Annual Meeting.

The Lodge having been closed, the members and visiting brethren dined together in the Connaught Rooms—W. Bro. Sheppard presiding as W.M. After the Loyal Toasts, the health of the W.M. was pledged at the call of W. Bro. Rae P. Normand, I.P.M., and W. Bro. Sheppard, after expressing his acknowledgments, proposed "The Immediate Past Master," who responded. To the toast of "The Initiate," submitted by the W.M., Bro. Claridge suitably replied; and W. Bro. Jacques Abady, P.M., L.R., gave that of "The Visitors," which was responded to by Bro. William Claridge, of the Harpenden Lodge No. 4314 (father of the initiate), Bro. B. L. Thomas, of the Centre Lodge, No. 3701, and Bro. H. F. Mainwaring, of the Sir Francis Drake Lodge, No. 4375. "The Past Masters and Officers of the Lodge," given from the chair, was acknowledged by W. Bro. E. G. Smithard, P.M., on behalf of the former, and by W. Bro. A. L. Croager, on behalf of the latter.

An excellent musical programme was provided.

Visitors at the Institution Meeting.

At the annual meeting of the Institution of Gas Engineers, which opens at the Institution of Civil Engineers on Tuesday, June 9, a number of distinguished visitors and members from overseas are expected. They will be welcomed at the commencement of the proceedings by the President, Mr. J. Ferguson Bell, M.Inst.C.E., of Derby. The Rt. Hon. J. H. Thomas, M.P., the Rt. Hon. Sir Alfred Mond, M.P., and Mr. Woolley (Chairman of the Derby Gaslight and Coke Company) will respond on behalf of the former, and the Hon. George Swinburne, of Melbourne, will speak for the latter.

FORTHCOMING ENGAGEMENTS.

[*Secretaries of Gas and Kindred Organizations are asked to assist in making this diary of events as complete and useful as possible by sending the earliest intimation of all meetings.*]

June 5.—Southern Association of Gas Engineers.—Visit to the works of the Bournemouth Gas and Water Company.

June 6.—Scottish Junior Gas Association (Eastern District).—Annual outing at Anstruther.

June 6.—Yorkshire Junior Gas Association.—Visit to the works of the Wakefield Gaslight Company.

June 6.—Society of Engineers.—Visit to Welwyn Garden City. A short descriptive lecture on the aims of the Garden City will be given by Sir Theodore Chambers, K.B.E.

June 8.—Institution of Gas Engineers.—Council meeting at No. 28, Grosvenor Gardens, at 2.15.

June 8.—Evening Star Lodge.—Regular meeting, at 5 p.m., in the Grand Temple of the Freemason's Hall, Great Queen Street, London.

June 9-11.—Institution of Gas Engineers.—Annual general meeting in the Great Hall of the Institution of Civil Engineers, Great George Street, Westminster. At the termination of Thursday's meeting, a Council meeting will be held at the Institution of Civil Engineers.

June 10.—Association of Statutory Inspectors of Gas Meters.—Annual general meeting at the new County Hall, Westminster. The afternoon will be devoted to a visit to the Finsbury gas meter testing office.

June 11.—Coke Oven Managers' Association (Midland Section).—Visit to the Barugh plant of Low-Temperature Carbonisation, Ltd.

June 12.—Institution of Gas Engineers.—Visit to Derby. Members should note that the luncheon will be in the Drill Hall, Derby—*not* the Assembly Rooms, as indicated in the programme.

June 19.—Industrial Gas Salesmen's Circle.—Meeting at the Council House, Birmingham. Inspection will be made of the industrial gas demonstration rooms and research laboratories of the Birmingham Gas Department, and visits will be paid to the Windsor Street heat treatment shops, and to the works of the Moss Gear Company, Ltd.

June 20.—London and Southern District Junior Gas Association.—Visit to the Cambridge Gas-Works.

June 30.—Last Day for Coke Competition Papers.

July 9.—Coke Oven Managers' Association (Midland Section).—Visit to the works of Messrs. Stainby and Lyon, of Knottingley.

July 20-25.—Royal Sanitary Institute.—Congress at Edinburgh. H.R.H. the Duke of York has accepted the Hon. Presidentship of this Congress, at which Sir John Gilmour, Bart., Secretary for Scotland, will preside, and deliver the Inaugural Address. A health exhibition is to be held in connection with the Congress.

SCOTTISH JUNIOR GAS ASSOCIATION.
(EASTERN DISTRICT.)

Visit to Leslie and Markinch.

The Association paid a visit to the gas-works at Leslie and Markinch on Saturday, May 16. There was a good attendance of members; the party including Mr. David Vass (Perth), and Mr. J. J. Scott (Cowdenbeath), honorary members.

Mr. Henry Gourlay, Manager of the Markinch Gas-Works, met the visitors at Markinch Railway Station, and the party proceeded to the Leslie Gas-Works. On arrival, they were received by Mr. John Letham, Manager of the Leslie Gas Company, Ltd.; and Mr. Anderson extended a hearty welcome on behalf of the Directors. A tour of inspection was made. A feature of the plant was a new setting of horizontals erected by Messrs. R. & G. Hislop, of Paisley.

The visitors then proceeded to the Markinch Gas-Works, where they were welcomed by Mr. Allan, Secretary of the Markinch Gas Company, Ltd. He expressed the hope that their present visit would be as enjoyable as the last, in 1921. Mr. Gourlay conducted the party over the works, and explained the various improvements and extensions which are to be carried out. An inspection of the gas engines at the power house of the adjacent water works completed a very interesting afternoon.

Following the inspection, the visitors were conveyed to the Town Hall, and hospitably entertained at tea by the Leslie and Markinch Gas Companies.

Mr. Alan Clark (Perth), Vice-President, in the absence of Mr. Laing (Brechin), the President, expressed the thanks of the members for the enjoyable and interesting afternoon they had spent.

Mr. Anderson replied on behalf of the two Companies. I remarked on the benefits which accrued from membership the Scottish Junior and kindred Gas Associations, both to mer bers themselves and to the undertakings they served. T intercourse between members engaged at different works, a the present-day facilities afforded for inspecting other wor and plant, were of valuable assistance. In his opinion, a wid application of the same principle to other industries wou greatly improve industrial conditions generally.

Mr. David Vass (Perth) added a few words in appreciati of the visit and the courtesy with which they had been w comed.

The concluding item on the syllabus of the Association this session is the annual outing, which will be held at A struther on Saturday, June 6. An inspection of the Anstruth Gas-Works, and also an oilskin factory, will take place in t forenoon. After luncheon, at the kind invitation of t Anstruther and Cellardyke Gas Company, Ltd., golfing a bowling competitions will be held; the visit concluding with i in the Gas Company's showrooms. On this occasion, la friends of members are cordially included in the invitation.

FORMS OF PYRITES IN COAL.

At a recent meeting of the Manchester Geological and Mini Society, Mr. J. Lomax read a paper, entitled "Further I searches on the Various Types of Pyrites in Coal, Especially Relation to Spontaneous Combustion," based upon work d in the laboratories of the Lancashire and Cheshire Coal I search Association. From this the following extracts have b made.

Crystalline Pyrites is often found in strong coals, but seldom noticed, on account of being enclosed in a pocket-l lenticel. Some lenticels are quite small; others comparativ large. When broken, they are found to contain well-formed beautiful crystals. Under normal conditions these are usu non-oxidizable, and therefore harmless from the point of v of spontaneous combustion.

Massive Pyrites consists of irregular blocks, which frequen occur as lenticels, usually embedded in a matrix of soft c The coal matrix is very friable, and on exposure quickly comes detached, leaving the pyrites free. Originally th blocks were pieces of wood of varying sizes; the vegetative structure could still be detected. This type is often found coal seams, especially in the Lower Coal Measures. The c clusion with regard to the massive banded pyrites is though on the surface they are apparently harmless, they rap oxidize under favourable conditions, and must therefore classed among the dangerous types.

Nodular Pyrites occurs as round, oval-shaped nodules in grades of coal, but is most frequent in the soft inferior co the vitrain or clarain varieties. Often such coal is trave by vertical joints, some filled with pyrites. Between the rain and the pyrites there is a thin layer of fusain. Such la cause splitting of the coal in the immediate area. A l block of moderately hard coal, in which a layer of this soft occurred, was cut-out to separate it from the surrounding m After five days' exposure in a dry room the coal surrounding pyrites was broken-up by a large number of radial cracks, the more fragile material in contact with the pyrites fell dust and slack. When this type of pyrites occurs in quanti under favouring conditions, it is undoubtedly a source of s taneous combustion.

Stringy Pyrites occurs in most coal seams; the string veins running parallel with the bedding planes of the coal specimen obtained from the Deep Mine of the Wimble Colliery Company at Hednesford was of an unusual chara the strings or veins occurred at right angles to the bed planes of the coal. The structure of the coal substance similar to that of many other coal seams. It was compos bands of soft coal easily fractured. The constituents chiefly the remains of vitrainized wood, broken-down laminæ, thin layers of microspores, occasional megasp resinous bodies, and small lenticels of fusain. It was a cult matter to estimate whether this type was a source of da as the strings were usually found in a fully pyritized condi but it was very seldom that oxidation took place. It may, t fore, be regarded as harmless under normal conditions.

Globulites.—In many coal seams there frequently occur l and lenticels composed of myriads of small shot-like b To this form of pyrites the term "globulites" was ap Usually a brown substance forms the inner portion, and p forms the outer shell or crust. Occasionally, they are posed of pyrites only. These bodies have undoubtedly bee rived from vegetative tissues. Globulites occur in all cl of coal as isolated bodies or aggregations forming ban varying thickness. They are not regular, although they extend over considerable areas. If partially pyritized, v is usually the condition in which they are found in the classes of coal, oxidation as a rule is very rapid, and the is quickly reduced to fine slack.

"FIELD'S ANALYSIS" FOR 1924.*

HE new edition of "Field's Analysis" dealing with the gures for the year 1924 has just come to hand, and, as usual, found to provide many interesting facts for the consideration all and sundry connected with the gas industry.

There is nothing special to remark upon in the make-up of is year's publication, which is issued in the form to which e are now becoming accustomed, and which still retains (as e think it should) working results based upon per 1000 c.ft. gas sold as well as per therm. There may be some, but irely very few, in the industry who would be prepared to say iat the per 1000 c.ft. basis could, in this work, be done away ith altogether, even in the event of the whole of the under-kings coming under the Gas Regulation Act.

In reviewing the figures presented to us in the past, it has een our custom to confine attention to groups rather than to dividual undertakings; but on this occasion it is proposed to apart from this practice, as there is an exceptional fact to cord. We make no apology for so doing, as it has reference the largest, and therefore the most important undertaking the country—viz., the Gas Light and Coke Company. On rning to p. 6 of the "Analysis," we find under "Net Coal and 'orking Expenses" a column which represents the total cost working without taking into consideration capital charges any kind; and this shows that the Gas Light and Coke Com-iny accomplished the feat for the first time within memory of eating not only their immediate neighbours but also all the uburban Companies included in the Analysis. Comparisons, course, are odious; but the Gas Light and Coke Company ave so often stood the brunt of adverse criticism in the past—erited or otherwise—that no one will object if the limelight is ow turned in other directions in order that this Company may eceive whatever praise is due to them. For this purpose there in be no better comparison than that provided by the South letropolitan Company, who have always been regarded as a odel Company. In their case the total cost is 7·686d. per nerm, as against 7·509d. for the Gas Light and Coke Com-iny. The main items comprising these figures are as follows:

	Gas Light. Per Therm. Pence.		S. Met. Per Therm. Pence.
Net coal	1·658	..	1·636
Manufacture—			
Salaries and wages	0·562	..	0·756
Purification	0·057	..	0·166
Wear and tear	1·740	..	1·542
Distribution	2·081	..	2·266
Rates and taxes	0·678	..	0·340
Management	0·366	..	0·515
Co-partnership	0·094	..	0·178
Other charges	0·273	..	0·287
	7·509	..	7 686

From this statement it will be seen that the disadvantage of aving a larger rateable value (in consequence presumably of ie greater gross profit that has to be made by the Gas Light nd Coke Company), bringing in its train an excessive charge or rates, is overcome by less expenditure in other directions. Vear and tear of works plant is higher; and it is interesting refer to the expenditure under this head during the last our years—*i.e.*, since the introduction of the Gas Regulation ct. The figures extracted are as follows:

	Gas Light. Per Therm. Pence.		S. Met. Per Therm. Pence.
1921	2·707	..	1·774
1922	2·573	..	1·723
1923	2·271	..	1·618
1924	1·740	..	1·542

he question immediately arises as to the effect of this greater xpenditure upon the price of gas. Here, however, we find iat the policy has not had a detrimental effect, as, notwith-anding this larger expenditure, the price of gas charged by ie Gas Light and Coke Company, as shown by the "Net Gas ental," is only increased by 50 p.ct. over pre-war days—viz., om 5·37d. per therm in 1913 to 8·11d. in 1924—a moderate ercentage when compared with most other commodities. One f the reasons for this is, of course, the fact that the post-war apital charge is very little greater than that experienced in re-war days—a fact which is all to the advantage of the con-umers.

This matter, in its bearing upon the charge which the con-umers might reasonably be called upon to pay, can be viewed n another way—viz., by taking the position of the Gas Light nd Coke Company in pre-war days relatively with the South letropolitan Company. The "Net Gas Rental" charges in 913 for these Companies were as follows.

Gas Light	5·369d.
South Metropolitan	4·415d.

f the percentage of difference that existed then is applied to the South Metropolitan prices from 1921, we obtain the following figures:

	Net Gas Rental—Per Therm. Pence.
1921	12·623
1922	12·374
1923	9·907
1924	9·187

Whereas the actual figures for the Gas Light and Coke Company were:

	Per Therm. Pence.
1921	13·117
1922	11·205
1923	8·861
1924	8·110

On this basis there is a total reduction over the period of no less than 2·798d., which would have been further enlarged to 5·432d. had it not been for the increased expenditure of 2·634d. on "Wear and Tear, Manufactory."

Translating the charge of 5·432d. per therm into its cash equivalent, we arrive at a sum of over £3,000,000, of which it may be said the consumers have received one-half, the balance having been spent on further improvements in the works of the Company, in order that the benefit of still cheaper gas may be in store for them—a fact which would appear to be already indicated by the success achieved during 1924.

That inferences such as these can be arrived at by reference to present and past editions of the "Analysis" illustrates in a marked degree the value of the material furnished by the work; and it would almost appear to make it imperative that the familiar red covers should lie within easy reach of every gas manager or official concerned in administrative work in the industry.

With regard to the other figures to be found in the "Analysis," attention should be drawn to the continuance of the splendid progress that has been such a marked feature throughout the industry generally during the last few years. The year under review was, in fact, a culminating one, since only one undertaking out of the 35 dealt with experienced a decrease—viz., Widnes—who were unfortunately down, but only to the very small extent of ¼ p.ct. The average increase for the whole of the undertakings included in the Analysis was no less than 6½ p.ct.—a result which was contributed to by a satisfactory increase in the number of consumers of 3·3 p.ct., and a still more satisfactory increase in the number of stoves let out on hire of no less than 7·42 p.ct. The Richmond Company disappear from the Analysis, as they have been absorbed by Brentford; but the vacancy is taken by the North Middlesex Company, whose advent into the charmed circle is heralded by a winning figure in the vitally important matter of output—an increase of no less than 14½ p.ct. having to be recorded. In the London area—presumably on the same day—every Company but one reached its maximum output, some very fine figures being recorded. Among the Provincial Companies it is noticed that in two cases—viz., Newcastle and Sheffield—the figures are increased as against the corresponding figures of a year ago by reason of amalgamations with other smaller concerns.

As was to be expected, many deficits are shown in the case of the undertakings which ended their year on Dec. 31 last, in consequence, of course, of the slump that began to show itself in the market for secondary products towards the latter part of last year. In the case of the Corporations, where the year ends at an earlier stage, there is only one deficit—viz., that of Edinburgh.

The effect of the decline in the secondary products market can be gauged from the following figures, which show in the first place the cost of coal per therm for the two years 1923 and 1924, and, secondly, the cost of "Net Coal" over the same period:

Cost of Coal per Therm Sold.

	Gas Light. d.	Comml. d.	S. Met. d.	Met. Cos. d.	Subn. Cos. d.	Provl. Cos. d.	Dublin Co. d.	Provl. Corpns. d.	Scottish Corpns. d.
1923	4·919	5·685	4·999	4·995	5·991	4·842	6·245	4·926	4·410
1924	4·875	5·906	4·986	4·975	5·832	4·978	6·659	4·583	4·724

"Net Coal" per Therm Sold.

1923	1·465	1·366	1·292	1·405	2·647	1·767	1·663	1·971	1·393
1924	1·658	1·848	1·636	1·663	2·859	1·994	1·378	1·243	1·182

It will be seen that, while the cost of coal has remained more or less stationary, the charge for "Net Coal" has progressed upwards in all cases with the exception of the Dublin Company and the Corporations; the reason for this latter exception being found in the fact mentioned above—that the year for the Corporations is completed at an earlier stage.

It is impossible to give an adequate review of a work of this kind, in which every figure, every line, and every column tells a tale. There is almost inexhaustible interest in the work, and upon it we heartily congratulate the Editor, Mr. H. E. Ibbs, and all who have assisted him in any way in securing and preparing the data, which, in large part, record the continued and material advance of the gas industry in the service of the community.

* "Field's Analysis of the Accounts of the Principal Gas Undertakings in England, Scotland, and Ireland," for 1924. London: Eden Fisher & Co., Ltd. Price £2 2s. Orders may also be sent to the "JOURNAL" Office.

NATIONAL GAS COUNCIL OF GREAT BRITAIN AND IRELAND.

SEVENTH ANNUAL GENERAL MEETING.

THERE was a very large attendance of members at the seventh annual general meeting of the National Gas Council, which was held on Tuesday afternoon of last week, at the Hotel Great Central, Marylebone Road, London, N.W.; and an innovation was the presence of members of the General Press. Mr. D. MILNE WATSON, D.L., occupied the chair at the meeting, and also at a luncheon which followed.

At the opening of the proceedings the minutes of the sixth annual general meeting, having been circulated, were taken as read, confirmed, and signed.

MEMBERS OF THE CENTRAL EXECUTIVE BOARD REPRESENTING DISTRICT EXECUTIVE BOARDS AND ASSOCIATED BODIES.

The SECRETARY (Mr. W. J. Smith) reported the following list of members of the Central Executive Board appointed and nominated respectively by the District Executive Boards and Associated Bodies:

Eastern District.—Messrs. T. Glover, C.B.E., M.Inst.C.E., Norwich; W. H. Mainwaring, Lincoln; R. G. Shadbolt, Grantham; and W. W. Townsend, Colchester.

Irish District.—Messrs. R. Bruce Anderson, A.M.Inst.C.E., Waterford, &c.; W. J. Grey, A.C.A., Dublin; Joseph McNicholl, Cork; and J. D. Smith, J.P., M.Inst.C.E., Belfast.

London District.—Messrs. F. J. Bradfield, F.C.I.S., Commercial; Archibald Caddick, Croydon; Thomas Hardie, M.Inst.C.E., Gas Light and Coke; and Frank H. Jones, M.Inst.C.E., Wandsworth, &c.

Manchester District.—Messrs. G. S. Frith, Runcorn; Fred. A. Pye, Chester; W. J. Smith, B.Sc., Bolton; and S. Tagg, M.Inst.C.E., J.P., Preston.

Midland District.—Messrs. Leslie E. Clift, Redditch; Harold Davies, Chesterfield; P. N. Langford, Coventry; and A. W. Smith, Birmingham.

Northern District.—Messrs. Norman S. Cox, Sunderland; Herbert Lees, A.M.Inst.C.E., Hexham; Thos. P. Ridley, F.C.I.S., Newcastle-on-Tyne; and F. P. Tarratt, Newcastle-on-Tyne.

Scottish District.—Messrs. Lawrence Hislop, Cowdenbeath; J. W. Napier, Alloa; Bailie R. G. Slorach, B.L., Hamilton; and Councillor James Stewart, Edinburgh.

Southern District.—Messrs. C. F. Botley, M.Inst.C.E., Hastings; Wm. Cash, F.C.A., Bournemouth; H. C. Head, M.Inst.C.E., M.I.Mech.E., Winchester; and A. Valon, M.Inst.C.E., Westgate and Birchington.

South Wales District.—Messrs W. Clark Jackson, A.M.I.Mech.E., Neath; W. H. Johns, M.I.Mech.E., Swansea; and J. E. Kenshole, Merthyr Tydfil.

South-Western District.—Messrs. J. H. Ellis, Plymouth; S. E. Halliwell, Bristol; S. J. Ingram, Truro; and W. N. Westlake, Exeter.

Yorkshire (W.R.) District.—Messrs. Harold E. Bloor, B.Sc., B.Eng., York; E. H. Hudson, Normanton; Arnold E. Mottram, Ossett; and C. Wood, O.B.E., F.C.S., Bradford.

Institution of Gas Engineers.—Messrs. J. Ferguson Bell, M.Inst.C.E., Derby; C. F. Botley, M.Inst.C.E., Hastings; Samuel Tagg, M.Inst.C.E., J.P., Preston; and John Wilkinson, O.B.E., Nottingham.

British Commercial Gas Association.—Messrs. R. Halkett, Sheffield; Ald. J. H. Lloyd, M.A., J.P., Birmingham; Ald. F. S. Phillips, J.P., Salford; and D. Milne Watson, D.L., Gas Light and Coke Company.

Gas Companies' Protection Association.—Messrs. R. W. Edwards, Aldershot; D. H. Helps, M.Inst.C.E., Reading; and A. A. Johnston, Brentford.

THE REPORT.

The annual report, which was then submitted, will be found in last week's "JOURNAL," p. 586.

MR. MILNE WATSON'S ADDRESS.

The PRESIDENT, who was received with applause, said: It is now my duty to move: "That the annual report and audited statement of accounts for the twelve months ended March 31, 1925, as circulated, be approved and adopted." Before, however, proceeding to put that motion to the meeting, I have one or two things I should like to say to you with regard to past happenings and the present position of the gas industry.

Even a casual glance through the report will show that, as in previous years, the matters dealt with by the Council have been both numerous and varied. We have every reason to congratulate ourselves upon the results achieved and upon the progress made in assisting the gas industry to perform the important—I may say, indispensable—services which it renders to the community.

I do not propose to-day, however, to traverse the ground covered during the past twelve months, important though much of the work has been, but will confine my remarks to one or two subjects which are of outstanding interest and importance not only to the industry, but to the nation at large.

At the outset I would like to refer to an innovation which has been introduced this year. In past years it has been our custom on the occasion of our annual meetings to refrain from drawing public attention to the invaluable services which we, as an industry, are performing. To-day we have set aside our customary modesty, and have invited to join us members of the Press—to whom I feel sure you would like me to extend the most cordial welcome on your behalf—in order that they, at any rate, may be apprised of the national importance of our industry. Their presence here to-day is peculiarly opportune, as it will, I believe, ensure that we in the gas industry get fair play and a square deal in connection with any proposals put forward for artificially stimulating electricity supply.

SCIENTIFIC PROGRESS OF THE INDUSTRY.

The scientific progress made by the gas industry in recent years has been remarkable, and, as one would expect, this progress has been accompanied by a great expansion in the demand for gas. In 1902, the sales of gas in Great Britain amounted to no less than 160 thousand million feet. That figure had risen to 181 in 1907, to 205 in 1912, to 232 in 1917, to 265 in 1922, and this enormous output was yet larger in 1923, when it reached 274 thousand million feet. The figures for 1924 will doubtless show a still greater sale of gas, but even taking the sales for 1923, the increase over those of 1902 is more than 70 p.ct.—a record of which we are all very proud.

This remarkable achievement, which has been due in no small measure to the work undertaken by the British Commercial Gas Association in familiarizing the public with the innumerable ways in which gas can be made to meet the needs of both the industrial and domestic consumer, may to the layman seem phenomenal; but to those of us who are of necessity familiar with the fuel problems of the world, the outstanding position which the gas industry in this country occupies is not, perhaps, so surprising.

Let us examine this subject a little more closely. Nations succeed and localities prosper according as they are blessed with natural resources, and to the extent to which they can successfully adapt such resources, on economic principles, to the best needs of mankind. Natural wealth and natural resources predetermine the particular industry and trade upon which a nation or locality must rely for its prosperity, be it dairy-farming in Denmark, the timber trade in Scandinavia, or cotton-spinning in Lancashire. Conversely, a nation which endeavours to force—as it were in a hot-house—the growth of exotic trades and industries in its midst must ultimately fail in its object.

THE FUEL PROBLEM.

If this subject be investigated yet further, it will be found that the foregoing generalizations are equally applicable and true to-day in connection with the fuel problem existing in this and other countries.

I do not, of course, for one moment suggest that electricity does not fulfil most useful functions in its own special sphere in this country. Thanks to the skill and energy of those engaged in that industry, these functions are most admirably performed. Moreover, electrical apparatus made in this country is known for its excellence throughout the world, and I believe that those engaged in its manufacture, equally with those concerned in the supply of electricity, are second to none in scientific knowledge, resourcefulness, and initiative. I wish to make it clear that we in the gas industry in no way belittle the services of electricity—gas undertakings themselves employ electricity in their works—but I do most strongly emphasize the elementary axiom that this country's greatness has been due in the past, as it is due to-day, to its natural fuel resources. It was the discovery of coal-fields adjacent to iron deposits, and to the sea-board, which made these small islands the "factory of the world." This country has been blessed with fuel resources—other countries with natural water power. The absence of water power in these islands has proved no handicap, as water power is merely an alternative to coal, with which this country has been richly endowed. The broad result has been, as one would naturally expect, that, while in other countries where water power is available the development of electricity supply has been most marked, in this country, where coal is the prime asset, it is the gas industry which has been more successful in meeting the needs of the community.

The gas industry has, after an existence of over one hundred years, become the principal conservator of our invaluable coal supplies, converting them—as it does—into a purified fuel which is easy of transport, capable of storage, and readily adaptable to a thousand uses.

It is due to the fact that the gas industry has concentrated upon the natural resources available and upon their most

economic utilization that its position in this country has become unexcelled—if, indeed, it is equalled—in any other part of the world.

Any comparison between the gas and electricity industries in this and other countries whose natural resources are entirely different must, of necessity, be misleading. Great Britain, with its ample coal resources, must inevitably rely upon the development of the use of gas for fuel purposes, just as the absence of coal resources may compel Continental countries to employ electricity even for heating.

In this country, for both industrial and domestic heating, the use of gas is, by universal consent, admitted to be in all cases the most economical, and in many cases the only practicable, method. I am leaving out of consideration the question of lighting, whether it be by gas or by electricity, as no one can suggest that this is a material factor in the question we are now discussing. The one field in which it can be alleged to-day that electricity leads is power, and admittedly cheap power is very important for this country.

This brings us to this question: Is the cost of power supply in this country excessive? As the result of many inquiries, I find that this is far from being the case. On the North-East Coast electricity for power purposes is as cheap as in Chicago, and twice as cheap as in Switzerland, and in any case it only represents something like 1½ p.ct. of the total manufacturing costs.

In a representative engineering works, I have ascertained that power represents only 0·8 p.ct. of the total manufacturing costs. It is clearly not high power costs in this country which are the cause of trade depression. In fact, even if power were supplied for nothing, it is impossible to suggest that this could result in any appreciable improvement in the trade of the country.

The fact, however, that electricity is employed in this country on a smaller scale than in other countries more favourably placed for its development has suggested to Members of Parliament that this may be one of the major causes of the present industrial depression in this country. Is this so? It is true that Switzerland consumes 700 units of electricity per head of population as against 139 units per head in this country; but this in itself proves nothing. Can current be purchased there at much lower rates than here? Decidedly not.

The essential fact is, as the Parliamentary Secretary to the Ministry of Transport stated in the House of Commons last week, that Switzerland "pays twice as much for its current as we in the North-East of England do." How can it be said then that Switzerland has the advantage?

If electrical enthusiasts were right in their premises, one would expect to find on the North-East Coast infinitely less unemployment than obtains in Switzerland. Is this the case? Most decidedly not! In fact, I do not think I am exaggerating when I say that trade depression and the number of unemployed on the North-East Coast are as great if not greater than obtain on the Continent. Cheap electricity does not spell good employment. Power costs in industry are but a small (and in many cases an almost negligible) factor. This point cannot be over-emphasized; and if it had not been overlooked, I do not believe that Parliament would be following this will-o'-the-wisp to-day. But let us pursue our comparison with the Continent still further. If small consumption of electricity per head of population were a cause of unemployment, it would necessarily follow that other countries with a consumption comparable with our own would be similarly burdened with the problem of the unemployed. Do facts support this theory? Far from it. Both France and Germany consume very little more electricity per head than we do in Great Britain, and yet, as we are all well aware, unemployment in those two countries is practically non-existent. If study is given to the question, it is clear that the consumption of electricity in this country has but little, if any, relation to the volume of unemployment. Sir Robert Horne himself frankly admitted last week that he had been one of those who had talked in "very round enthusiastic language" on the subject, and stated: "My study of this matter has convinced me that we have talked a little bit wildly of what can be immediately achieved by the development of electrical schemes." This view was confirmed by Colonel Moore Brabazon, the Parliamentary Secretary to the Ministry of Transport, who issued a timely warning against exaggeration in connection with "what electricity could do for the people." I am glad to think that at last, owing to our efforts, some idea of the truth is beginning to dawn upon them.

Happily we have a sane Government in office; and—as one would expect—during the debate on this question last Thursday, both the Minister of Transport and his Parliamentary Secretary refused to be hustled into giving a hasty verdict on so vital a question before they had time to study the whole subject.

The Electricity Proposals.

To gain a clear perspective, I must once again refresh your memories by referring to the only definite proposals which have hitherto been put forward—viz., those propounded by Mr. Snowden, the late Chancellor of the Exchequer, last year. He, you will recollect, proposed to grant subsidies out of the National Exchequer for the development of electricity in this country, first, in order to establish a uniform frequency, in which connection he mentioned a figure of ten million sterling; secondly, for the purpose of the laying of main transmission lines in cases where the undertakers had no intention in the near future of laying such lines with their own resources—in other words, where the laying of such lines would be an uneconomic proposition; thirdly, for the development of electricity in rural areas, including the electric lighting of cottages and the so-called general improvement of the amenities of country life.

It is interesting to note that Mr. Snowden admitted last week that his ultimate aim and object was to achieve the nationalization of the electricity supply industry. He stated:

> "My confidence is such that I would not hesitate even to spend public money in improving the undertakings which are still in the hands of private companies, knowing full well that the time will very quickly come when we shall buy out those private companies, and then what assistance they have received from the State will be taken into consideration in estimating the price."

I can hardly believe that a Conservative Government will take any steps which will pave the way for that ultimate nationalization which Mr. Snowden is so eagerly anticipating.

Reverting to the actual proposals which have been put forward, I must confess that I was surprised to find that visionaries are still to be found who regard the extension of electricity supply to rural districts as an economic and paying proposition, a proposition that will help the electricity industry to sell its commodity cheaply. So fantastic and fallacious are many of the statements in this connection, that it is difficult to know where to commence in refuting them. I do not think, however, I can do better than quote from the speech made by the Chairman at this year's general meeting of the Yorkshire Electric Power Company:

"Much has been said lately as to the use of electricity for agricultural purposes. It is, to my thinking, a beautiful dream of enthusiasts who have given very little thought to the revenue the farmer is willing to pay, as he now gets the power he requires from a small oil engine run for a very few hours a day.

"The principal obstacle in the way is the cost of distribution. To make a connection to a high-pressure electric main involves an expenditure of at least £200, although the amount of power required may be very small. Practically, it is found inadvisable to provide such a connection for less than, say, 50 H.P. The average farmer requires from 10 to 15 H.P.

"We are supplying between twenty and thirty farmers, and our results show that our average expenditure is £300 for each supply, and that the annual use is very small.

"In other countries special attention has been given to the possibility of supplying farmers with electricity, but it is found—as we find in this country—that the small amount of supply which the farmer requires stands in the way of a general extension of use.

"In Sweden, for example, it is found that the use made by farmers does not exceed 20 units per acre per annum, and the difficulty of providing the supply at a price which would be attractive to the farmer is the same as in this country.

"In Denmark supply is offered to farmers at a central transforming or sub-station. From these centres the farmers jointly bear the cost of the distributing mains, but their method of construction of overhead lines is such as would not be permitted in this country, and the drop in pressure in the long lines makes the lighting of little value when the main power supply is required.

"In France they are finding the same difficulty of a small use by the farmers. So much has been said about the use of electricity for agriculture that I thought these very few short facts would be rather interesting to the shareholders of the Company."

These are the words of the Chairman of an important electric power company, and most useful, in my judgment, for the whole country. I venture to commend them to the notice of Mr. Lloyd George, who has recently referred to what France and Denmark are doing with regard to electricity supply in rural areas. He even went so far as to give the views of an electrical expert, whom he quoted as saying that, in agriculture, electricity "would really double the produce." A careful search has failed to discover this statement, but in any event I do hope that Mr. Lloyd George and other Members of Parliament will not be carried away by these dreams and visions. It is extremely improbable that the farming community will avail themselves of electric current even when carried through rural areas, as they will find it is cheaper and more convenient to use an inexpensive and mobile internal combustion engine. To-day, those who farm on only a modest scale have their own motor tractors, and can—and do—utilize these on the farm for power purposes, such as grinding corn, chaff and root cutting.

So much for the blessings of electricity for those engaged in agriculture.

I now return to the other proposals—viz., the co-ordination of the type of supply, the interconnection of stations, and the laying of main transmission lines. These questions naturally hang together. It would be out of place at this meeting to discuss the technical aspects of the case, but I would like to refer to a statement recently made by the President of the Institution of Electrical Engineers, who pointed out that "the

carriage of coal from (say) South Wales to London, for the purpose of generating electricity at stations in London, is more economical than the establishment of generating stations in the coal-field and the transmission of electricity from the coal-field to the Metropolis."

Does it not therefore follow that the laying of great lengths of electric cable will increase, and not reduce, the cost of supplying electricity, and that money spent thereon will be money absolutely wasted, unless those cables are the means of providing a greatly increased demand, without which cheaper electricity is impossible?

You will have seen from the extract which I read to you that the electric power companies expect no assistance in this respect from the rural areas. I am therefore compelled to ask the all-important question—viz., Who is to find the money required to carry out this costly experiment?

If it is both sound and remunerative to adopt these proposals, why does not the electricity supply industry itself undertake the work? What ails electricity? Is the industry "depressed?" Far from it. Their financial resources are great. They have every facility for raising capital on highly favourable terms. If they have not the necessary legislative powers for joint working or amalgamation, Parliament can grant them; but the gas industry is entitled to—and does most emphatically—protest against any suggestion that State aid should be afforded to the electricity supply industry for "putting its own house in order." Any financial assistance from the Government, whether it takes the form of a guarantee or cheap money, or a direct grant, must of necessity react most seriously upon the gas industry, which to-day, in free and fair competition, can well hold its own against its rival.

In truth, the motive which underlies all these proposals is the desire to attain a high load factor in the *only* way in which it can ever be attained—and herein, to my mind, lies our greatest danger—by taking from us by means of State aid those domestic consumers we already serve. Electricity covets most of all the domestic load carried to-day by the gas industry. The Parliamentary Secretary to the Ministry of Transport himself, dealing last week with electricity, regretfully referred to the fact that "only 15 per cent. of the power generated in this country was used for domestic consumption." Be it always remembered that the domestic load is a fuel load—a load which in this country (as I have already indicated) is peculiarly and properly the province of the gas industry.

Again, what benefit would accrue to either the nation or the consumer if some State-aided scheme of electrical development were to enable electricity to be used in place of gas for fuel purposes? Benefit there would be none. On the contrary, the country would suffer irreparable loss. The employment of electricity for fuel purposes must always entail serious and unnecessary waste, and for this reason—that whereas 85 p.ct. of the total heat value of the coal is conserved when carbonized at the gas-works, the most efficient generating station utilizes only 20 p.ct., and wastes 80 p.ct. of the heat in the coal.

Such a policy would inevitably necessitate not only an enormous increase in the quantity of coal consumed, but—more serious still—the complete destruction of the numerous bye-products obtained from gas manufacture, indispensable alike in peace and war.

In conclusion, I contend that "robbing Peter to pay Paul" is not only inequitable, but is bad business, and I feel sure that no such policy would ever have been advocated in this country were it not for the fact that we are now passing through a period of unexampled trade depression. Statesmen are at their wits' end to devise schemes for remedying unemployment. Industrialists in many cases are disheartened and despondent. The community clutches at straws. At such a time it is more than ever essential that we should, every one of us, steady our nerves, maintain a true perspective, and, above all things, discourage panic legislation. I have no fear but that our industrial community will, if left to itself, achieve its own salvation in this respect. But I do most greatly dread and distrust any efforts of the Legislature to solve an industrial problem by Act of Parliament. [Applause.]

The Accounts.

Mr. William Cash, F.C.A. (a Vice-Chairman of the Central Executive Board) said he rose to second the resolution which had been moved by the President At the same time, and in the first instance, he would like to bear testimony to the very valuable, interesting, and instructive address by the President to which they had just listened. ["Hear, hear."] He thought that such an address as that, delivered on such an occasion as the present one, must afford the greatest encouragement to them all, and prove of the utmost help to them individually in dealing with the situation as it existed to-day. Turning to the report itself, they would find in it a record of very good work done during the past year; and as far as the attached accounts were concerned, they were set-out in such a form that the members could see for themselves what the receipts and expenditure for the year had been. He would merely draw their attention to two items. First, on the receipts side, they would see, under revenue, that the net receipts for the year were £16,436; whereas for the year to March, 1924, the amount was £13,930. Thus they had every reason to feel encouraged on this head. As regarded the expenditure side, there was one new item—£1000 granted to the Institution of Gas Engineers. Under "British Empire Exhibition" this year was included the cost on account of erecting a Tar Exhibit. The result of the year's working was a surplus of £27.

The Municipal Point of View.

Councillor James Stewart (Edinburgh) said that as a representative of a municipal undertaking, he had very great pleasure in associating himself with the remarks of the President and Mr. Cash. The gas industry, as they all knew, was one of the most important in the country, and was making progress against all competition. This was very largely due to the efforts of the National Gas Council, which since its inception had done a great deal to advance and popularize the use of gas. Without a Council such as that, each undertaking would have been "ploughing its own lonely furrow," without any great success. The report was very satisfactory, and showed good results, in which all the undertakings of the country equally shared. There was a good future for gas, and they knew that the efforts of the Council would greatly assist in its development. They fully recognized the benefits that were being derived from the efforts made by the Council to combat the proposals in regard to electricity.

The resolution was then put to the meeting and carried unanimously.

The President.

Sir Arthur Duckham, K.C.B., said it was his pleasure to propose the re-election of Mr. Milne Watson as President of the National Gas Council. Mr. Milne Watson had remarked earlier that they were not politicians in that room; but he (the speaker) would beg to say that they had a statesman as their leader. The whole of the gas industry looked to Mr. Milne Watson as its leader—a very worthy leader, a man who had done colossal work on behalf of them all, and to whom they looked for further work, and even more important work, as the times became more difficult.

Mr. Milne Watson had referred to this as being the first meeting of the National Gas Council held with the general Press present. He agreed with him, that they in the gas industry had really not "gassed" publicly enough about themselves. In the war he (Sir Arthur) had nothing whatever to do with the gas industry; but incidentally he controlled the electrical industry of this country. Think what the gas industry did for the nation during the war (it had been put on record very finely by the late Lord Moulton); the basis of explosives came from the gas industry; extraordinary efforts were made by the industry to supply the needs of manufacturers in regard to heat and power—and yet at the end of the war not one suitable reward was given to anyone in the industry, and no acknowledgment was made by the Government in any way of the services that had been rendered by the industry.

Gas as a Domestic Servant.

Further, he did not think people altogether realized that gas was the greatest servant of the public to-day. Its services exceeded those of any other public utility business. The whole of the domestic life of this country had been changed by gas; the lot of the housewife had been made in all ways easier. The gas industry was for the prevention of the smoke nuisance; and the improvement that had resulted to the air of the towns since gas had become a domestic servant was noticeable by everybody. Now one could see right across London on a Sunday morning; whereas, had it not been for gas, the domestic coal range would have been cooking the Sunday dinner—and the atmosphere would have been heavy. Then there was the call for solid smokeless fuel; and in the future the gas industry must be the medium for meeting that. The bye-products from gas-works were also of vital national importance. He did not think that all this was fully realized by the public, who did not seem to appreciate that the gas industry was a magnificent and a growing one—enormously strong, very active, and keeping its house in order by research. Further, the public did not realize that the gas industry—outside municipal ownership—could not increase dividends unless the price of gas was reduced, and that probably it was the only public service that had its dividends dependent upon the price charged for its commodity.

The Electrical Position.

Mr. Milne Watson had dealt very fully and very ably with the electrical position; and he felt certain that his remarks would make a great impression on all who read them. It was to be hoped that they would find their way into the hands of members of Parliament and Cabinet Ministers who would have to deal with a subject which might land this country in a very great and possibly ill-considered expenditure. The gas industry wished to see a prosperous country, which would mean a prosperous gas industry; and as cheap electricity made for prosperity they could assure the electrical industry that it would have their support, and not criticism, in any scheme put forward to develop properly the electrical industry for the benefit of the country. But here was a scheme which, at this time of heavy taxation and national expenditure, envisaged a further large drain on the resources of the country to carry out something

which had not been proved. All that the gas industry asked was that due consideration should be given to any scheme, not only by the electrical enthusiasts—by those who had their bread and butter to earn by being connected with electricity—but by everyone who was concerned with the supply of energy. All the gas industry had to fear was hasty legislation—hasty action on the part of the Government. If the scheme was properly brought forward, and time given for constructive criticism, he was certain it could not go through in the form which, from various statements, one might surmise was now proposed. Look at the speeches that were delivered in the House of Commons—such as Mr. Lloyd George stating the other day that it was very much cheaper to transmit energy in the form of electricity over long transmission lines than to transport the coal, when it was an absolute and positive fact that it was not cheaper, except for short distances. Take another statement made by the Minister of Mines, that the only hope for the coal industry was low-temperature carbonization. When men who had spent their lives in the fuel industry saw statements like these, it naturally made them nervous, and anxious that prompt measures should be adopted to prevent hasty action being taken on such vital subjects.

CENTRAL CONTROL.

There was a final point in regard to this electricity scheme to which he would like to refer—namely, that, as far as one could see, it was entirely based on central control in London. He thought this would be the greatest piece of revolutionary socialistic legislation ever seriously proposed. Many of those present were in charge of works which produced energy; and he thought they would all shudder at the idea of their activities being controlled by a central board. This he considered would be the one thing that would damn the scheme as propounded for electricity generation in this country. It was a thing which would be unworkable, and which must lead to nationalization. He would keep them no longer. The meeting had started well; for he was certain they had all been tremendously impressed by the President's address. They would all return to their various parts of the country ready to fight for their industry, and for the good of the country as a whole. [Applause.]

THE BLIND LEADING THE BLIND.

Alderman F. S. PHILLIPS, J.P., of Salford (a Vice-Chairman of the Central Executive Board), said he esteemed it a very great pleasure to be allowed to second the proposal that Mr. Milne Watson be again elected President for the ensuing year. As a member of the National Gas Council, of the Federation of Gas Employers, and of the National Joint Industrial Council for the Gas Industry, he could not conceive that they could possibly have found a gentleman better fitted for the work. Mr. Milne Watson's patience, courtesy, time, and influence had been given to them unstintingly, and had secured what he regarded as the phenomenal success of the National Gas Council and the other organizations. It was gratifying to think he would serve them yet for another year, and it was to be hoped for further years to follow. Might he (the speaker), as an old municipal representative of some forty years' standing, refer to the question of electricity in a few words? He did not understand why the politicians had got hold of this question of electricity, and why they were pushing it for all they were worth, as though it were going to be a panacea for all the ills from which the country was suffering. It was an absolute mistake. It showed him, as he got older, that he must put less and less trust in politicians. [Laughter.] They did not seem to understand the things they were talking about; and this pushing of electricity at the present moment was simply a case of "the blind leading the blind."

CIVIC PRIDE.

A few days ago, Mr. Lloyd George, in a debate, referred to municipal authorities. Now, a long experience of municipal authorities enabled him (Alderman Phillips) to say there was such a thing as civic pride in the work they were doing; and he ventured to assert that the work of civic authorities did not stand second to the work of the House of Commons ["Hear, hear."], either now or in days gone by. The work of municipal authorities had been good, and it was still good; and it claimed the best thought of the best men in the district. But what did Mr. Lloyd George say of it? Mr. Lloyd George referred in this way to the vested interests of municipal authorities. Remember, these vested interests had been created by Parliament:

> "You can put a price upon every other vested interest—it is sometimes very heavy—but the price of human vanity is prohibitive; and if you have got a chairman and an engineer and a clerk, all engaged in the working of one sort of little business upon which they make reports every year, the reports appear in the Press, and it is their own particular child. Then when a Chancellor of the Exchequer and Minister of Transport propose to take their baby away from them, it is without price so far as they are concerned, and therefore they object very much."

What could Mr. Lloyd George be dreaming about? Municipal authorities and their powers were the creation of Parliament, of which Mr. Lloyd George was a member. He had taken his part in creating these powers. If they were earnestly administered, was it right to turn round and say that it was vanity? Of course, they objected to their "baby" being taken away from them. Did anybody mean to tell him (the speaker) that the men who were elected by the ratepayers of a particular district or town, and were administering affairs on behalf of the citizens, could not do it better than a central board which was unacquainted with these affairs? Was there any sense whatever in the suggestion? Vanity was one thing; proper civic pride was another, and a desirable, thing.

MILLIONS AT STAKE.

As he had said, he was surprised at the politicians pushing this electricity matter. He himself was a member of the Electricity Committee, by request of his Corporation, as well as Chairman of the Gas Committee. Electricity must have its functions. He did not object to this; but he did object if it was going to be subsidized to the detriment of gas. There was no reason in the proposal; it would turn out to be a delusion, and was going to cause a great waste of public money. The whole business led one to hope that politicians would keep to their own particular business—whatever that might be—and leave industry alone. What was going to be the upshot of it all? If they did by this means destroy the gas industry, created by Parliament, with its powers granted by Parliament, what would be the position? So far as municipalities were concerned—and he was speaking for the moment particularly of municipalities working on money borrowed under the powers granted them by Act of Parliament—with a capital of some £58,000,000 needing to be repaid, where would the towns be, if the gas industry were destroyed? He resented very strongly that statements such as one heard and read now about electricity should be made without sufficient information, and without adequate knowledge, and which would tend to create a worse state of things than now existed. It was not by such means that they were going to get away from bad trade and out of difficulty; it was by steady application, on business lines, to the problem, and not on these lines of fancy, which had no truth and no solidity behind them. He did not think the final form of generation of electricity had yet been reached; there were too many processes between the burning of the coal and the transmission of the current. Improved methods would come some day.

The resolution having been heartily carried,

The PRESIDENT said: Thank you very much. I really do think it is high time you had a change ["No, no."]; but if you are anxious to back the old horse, the old horse will do the best he can for another year.

OTHER OFFICERS.

Mr. J. FERGUSON BELL proposed the re-election of Alderman Sir William Kay, J.P., as Hon. Treasurer, and of Alderman H. Wade Deacon, C.B.E., J.P., and Alderman J. H. Lloyd, M.A., J.P., as Trustees. He said the Council were fortunate in having such gentlemen to guide their destinies. He was sure the members would like to send a message to Sir William Kay expressing their deep regret that for some little time past he should have been in ill-health, and the wish that he might have a speedy recovery. He had been a member of the Finance Committee, and had taken an active part in the work of the Council. Alderman Wade Deacon and Alderman Lloyd were very well known in the industry, and were strong supporters of the Council.

Mr. CHARLES WOOD (Bradford) seconded the motion, which was passed.

On the proposition of Mr. C. F. BOTLEY (Hastings), seconded by Alderman J. H. WADDINGTON (Mayor of Halifax), the re-election of the Joint Hon. Secretaries (Messrs. F. W. Goodenough and W. E. Price, Assoc.M.Inst.C.E.) and the Auditor (Mr. Alfred Morland, F.C.A.), was approved.

VOTES OF THANKS.

The PRESIDENT moved a hearty vote of thanks to the Chairmen and Secretaries of the District Executive Boards for their services during the past year. These Boards, he said, were essential to the efficient working of the Council. It was through them that it was possible to keep in touch with what was transpiring in the Provinces. It was very important that they should have the opinions of the districts. The positions of Chairman and Secretary involved a great deal of work; and a vote of thanks was a very small token of appreciation of their important functions.

Mr. FRANK H. JONES, seconding, said he realized that they had very efficient headquarters, and this efficiency must be very much enhanced by the work of the District Boards.

Mr. G. HARDY-HARRIS (Exeter) and Mr. SILLITOE (Manchester) acknowledged the vote—the former on behalf of the Chairmen, and the latter for the Secretaries.

The PRESIDENT next proposed a vote of thanks to the Finance Committee for their unremitting labours.

Mr. THOMAS GOULDEN seconded this, and it was acknowledged by Mr. CASH, who referred to the excellent work of the staff.

The PRESIDENT, proposing a vote of thanks to the staff (which

was cordially agreed to), said he thought none of the many organizations with which he was connected had a better staff than the National Gas Council. Mr. Fottrell, Mr. Ogilvie, Mr. Smith, and those who worked under them, were all first class, and were devoted to the Council's interests. They were blessed with discrimination and great intelligence; and all who came in contact with them would agree that they deserved this vote.

Alderman Sir Albert Ball, J.P., moved a vote of thanks to the President for his able address, and for the way in which he had conducted the proceedings at that meeting. They realized, he said, that in Mr. Milne Watson they had the first man in the industry to-day—one who was exceptionally tactful, full of determination, and always ready to do everything humanly possible for the gas industry. It was the sincere wish of every member of that Council that the President might be spared for many years to lead them, to give them the benefit of his advice and help; and with such service as this, he was satisfied that the gas industry would prosper for generations to come.

Mr. Ferguson Bell seconded, with the remark that it required no words from him to commend this resolution to the hearty approval of the members. They were all aware of the great services of Mr. Milne Watson in respect of the Council. They were pleased to have him at their head; and they hoped to have him so for many years to come.

The President thanked the members, and added that it was a pleasure to preside over such an enthusiastic and determined gathering as they had had that day.

INSTITUTION OF GAS ENGINEERS.

Annual Report of the Council.

The following are the main portions of the report of the Council of the Institution of Gas Engineers for the year 1924-25, which will be submitted at the annual general meeting of the Institution, to be held in the Great Hall of the Institution of Civil Engineers, Great George Street, Westminster, S.W., on Tuesday, Wednesday, and Thursday, June 9, 10, and 11, under the Presidency of Mr. J. Ferguson Bell, M.Inst.C.E., Chief Engineer and General Manager to the Derby Gas Light and Coke Company.

Details of the programme for the meeting will be found on p 59 of the "Journal" dated April 1.

Membership.

Owing to the increasing number of applications for admission to the Institution, it was necessary to issue two balloting lists for the election of new members during the year.

The figures show that the net increase in membership was 55. The total number of members on the register at the end of that period was 1057. With the fifty candidates for election at the annual meeting, the total number on the register will be brought up to over 1100.

Class of Membership.	At Dec. 31, 1923.	Elected and Transferred in 1924.	Deceased, Resigned, and Transferred in 1924.	At Dec. 31, 1924.	Increase or Decrease.
Hon. members	24	..	3	21	− 3
Members	799	49	21	827	28
Associate members	126	43	9	160	34
Associates	11	1	1	11	..
Students	42	14	18	38	− 4
Total	1002	107	52	1057	55

The Council refer with gratification to the gracious consent of the Prince of Wales which enabled them to elect His Royal Highness an honorary life member of the Institution.

Since the last report was issued, the following have been transferred from the class of Associate Member to Member; and have been admitted as Students.

Transferred to the Class of Member.

Walter A. Barnett	Barnet.
Harry Curtis	Macclesfield.
Herbert C. Higgs	Basingstoke.
A. Graham Lane	Aylesbury.
David Muir	Pontypridd.
George W. Richmond	Beckton.
George Walmsley	Londonderry.

Admitted as Students.

Edward Morgan Edwards	Neath.
Alexander S. Grime	Brentford.
Ralph Halkett, jun.	Sheffield.
Terence H. Madden	Cardiff.
Alan H. Nicholson	Stockton-on-Tees.
Wilfrid Richard Quiller	Plymouth.
John Roberts	Bingley.
Albert E. Simpson	Nottingham.
Alexander G. Skinner	Redhill.
Reginald F. Thomson	Nottingham.
Benjamin Thorpe	Longwood.
John H. Wainwright	Tipton.
John E. Wakeford	Stockton-on-Tees.

Deceases.

The Council have to record, with regret, the deaths of the following members:

Sir George Beilby, F.R.S.	London.
Augustus F. Browne	London.
Charles C. Cawthra	Halifax.
Thomas Crossley	Guernsey.
P. B. Ellacott	Waterford.
Charles Franks	London.
Harry E. Jones	London.
John Lewis	Newcastle-on-Tyne.
Walter A. Sapey	Tamworth.
Stephen Temblett	Andover.
Thomas Watson	Rushden.
James Whimster	Armagh.

Of these, Sir George Beilby was an honorary member, and Mr. H. E. Jones a Past-President. Both of them rendered exceptional service in promoting the interests of the gas industry during a long life, particularly during the period of the war.

National Gas Council.

The representatives of the Institution on the Central Executive Board of the National Gas Council during the year 1924-25 have been Messrs. J. Ferguson Bell, Charles F. Botley, Samuel Tagg, J.P., and Thomas Goulden.

Affiliated District Associations.

The seven affiliated District Associations have been represented on the Council of the Institution during the same period as follows:

Eastern Counties Association	Mr. Edward F. Keable.
Manchester District Institution	Mr. Harold Davies.
Midland Association	Mr. William E. Caton.
North British Association	Mr. James Campbell.
North of England Association	Mr. Samuel Shadbolt.
Southern Association	Mr. Leonard J. Langford
Wales and Monmouthshire Institution	Mr. W. Clark Jackson.

Annual General Meeting.

The sixty-first annual General Meeting was held in the house of the Institution of Electrical Engineers, Victoria Embankment, on Tuesday, Wednesday, and Thursday, June 24, 25, and 26, 1924, under the Presidency of Mr. Samuel Tagg, Engineer and Manager of the Preston Gas Company. Particulars are included in the report.

British Engineering Standards Association.

The representatives of the Institution on various Committees of the British Engineering Standards Association consist of Messrs. J. G. Clark, Thomas Hardie, Alex. A. Johnston, and Albert Stokes.

With reference to the Sub-Committee on the Standardization of Gas-Valve Flanges, on which Mr. Hardie represents the Institution, agreement has been reached by the Sub-Committee of the Association and the Joint Committee of the Institution and the Society of British Gas Industries. The following table gives the dimensions which have been approved by the Sub-Committee.

For Working Pressures up to 30 Lbs. per sq. in. for Gas and 50 Lbs. per sq. in. for Water.

Bore.	Diameter of Flange.	Diameter of Bolt Circle.	Bolts.		Thickness.
			No.	Diameter. In.	
In.	In.	In.			In.
2	6	4½	4	⅝	⅝
2½	6½	5	4	⅝	11/16
3	7½	5¾	4	⅝	11/16
3½	8	6½	4	⅝	¾
4	8½	7	4	⅝	¾
5	10	8½	4	⅝	¾
6	11	9¾	4	⅝	13/16
7	12	10¾	8	⅝	13/16
8	13½	11¾	8	⅝	⅞
9	14½	12¾	8	⅝	⅞
10	16	14	8	¾	15/16
12	18	16	8	¾	15/16
14	20½	18½	8	⅞	1
15	21½	19½	8	⅞	1
16	22½	20½	12	⅞	1 1/16
18	25½	23	12	⅞	1 1/16
20	27½	25½	12	⅞	1⅛
21	29	26½	12	⅞	1⅛

The work of the respective Sub-Committees on Portable Photometers, Illumination Materials, and Fittings is being proceeded with, and will be reported upon when ready.

With reference to Sub-Committee 39/3, Standardization of the Methods of Testing and Specifying the Characteristics of Illumination Glassware and Translucent Materials of Sectional Illumination Committee 39/-, Mr. Stokes reports that satisfactory progress had been made by this Committee. A provisional draft of specification has been drawn up by the Sub-Committee dealing with the matters of quality, finish, dimensions, diffusing power, brightness, and efficiency of translucent glassware. Alternative methods of measurement—viz., the "flux" method and the "point-to-point" method—are recommended for adoption.

The following summary of the work carried out during the past year by the three Committees of the British Engineering Standards Association on which Mr. A. A. Johnston, of Brentford, represents the Institution, has been supplied by him:

(*a*) Sectional Committee on Machine Parts, their gauging and nomenclature.
(*b*) Sectional Committee on Pipe Threads.
(*c*) Sub-Committee on Steel Tubes.

With regard to Sectional Committee 10/- on Machine Parts, although no meetings were held during the past year a number of reports of its Sub-Committees were submitted to it by correspondence—namely: No. 164-1924, Limits and Fits for Engineering; No. 190-1924, Dimensions for B.S.W. Bright Hexagon Bolts, Set Screws and Nuts, Split Pins, Washers, and Studs; No. 191-1924, Dimensions for B.S.F. Bright Hexagon Bolts, Set-Screws and Nuts, Split Pins, Washers and Studs; No. 192-1924, Dimensions of Spanners.

No. 164 represents a satisfactory termination of a work which was full of difficulty, and should be of value in every department of mechanical engineering where interchangeability is required.

Nos. 190 and 191 should also prove a benefit to industry, as they represent the result of an agreement with the bright bolt manufacturers, by which the latter have undertaken to keep in stock the sizes shown in these reports.

Furthermore, the revision of the Tables on Black Bolts and Nuts is being undertaken, and a report on the lines of that for Bright Bolts and Nuts will, most probably, be submitted to the Sectional Committee in the near future; and the preparation of standards for cup-headed and countersunk black bolts for use in wagon construction, which has been asked for by the Railway Clearing House, will also be submitted.

No meetings were held by the Sectional Committee on Pipe Threads during the past year. Similarly in the case of the Sub-Committee on Steel Tubes, no progress has been made, owing to difficulties which have arisen in regard to the thicknesses and pressures coming under the designation gas, water, and steam.

International Commission on Illumination.

The sixth session of the International Commission on Illumination was held at Geneva from July 21 to 25, 1924. Mr. Robert Watson, of Doncaster, and Mr. Walter T. Dunn, Secretary of the Institution (owing to the unavoidable absence of Mr. W. J. A. Butterfield), attended as delegates; and their report will be presented at the annual meeting.

National Illumination Committee of Great Britain.

The Institution is represented on this Committee by Mr. W. J. A. Butterfield, Mr. J. G. Clark, Dr. H. G. Colman, Mr. F. W. Goodenough, and Mr. Robert Watson. The report of the Chairman (Col. Kenelm-Edgcumbe) for the year 1924 shows that important work is being carried out under the auspices of the Committee.

Wrought-Iron Tubing Committee.

This Committee consists of Mr. Albert Stokes as Chairman, Messrs. J. Ferguson Bell, J. E. Blundell, Fred Davies, Stephen Lacey, W. E. Price, Samuel Tagg, Frank P. Tarratt, and R. Hy. Ruthven as Hon. Secretary. Several meetings have been held, and the assistance of Mr. F. W. Harbord, F.I.C., Assoc.R.S.M., Consulting Metallurgist, has been obtained. The report of the Committee, together with draft of proposed specification which they recommend for adoption, will be communicated to the Institution at the annual meeting.

Institution of Civil Engineers Heat Engine and Boiler Trials Tabulation Committee.

This Committee has continued its work during the year. Several meetings of representatives of the co-operating bodies have been held. These bodies consist of the Institutions of Mechanical and Electrical Engineers, Naval Architects, Marine Engineers, North-East Coast Institution of Engineers and Shipbuilders, Institution of Engineers and Shipbuilders in Scotland, Institute of Chemistry, Institution of Gas Engineers, British Electrical and Allied Manufacturers' Association, British Engineers' Association, the Admiralty, the War Office, and the Air Ministry. The Institution's representatives on the Committee are Mr. W. Newton Booth, B.Sc., Mr. Walter Chaney, Mr. Harold Hollings, M.Sc. (taking the place of Mr. Stephen Lacey, B.Sc., who resigned), and Mr. E. W. L. Nicol.

Birmingham Medal.

The Council report with much gratification that the members of the Institution have unanimously endorsed their recommendation that the Birmingham Medal should be awarded in 1925 to Dr. Charles Carpenter, C.B.E., M.Inst.C.E. Arrangements have accordingly been made for its presentation at the annual meeting.

Shipping Engineering and Machinery Exhibition.

The Council have accepted an invitation for the Institution to be represented on the Committee of the Shipping Engineering and Machinery Exhibition which is to be held at Olympia from Nov. 23 to Dec. 5, 1925. Mr. Charles F. Botley, M.Inst.C.E., has been appointed to act in that capacity.

Public Works, Roads, and Transport Congress and Exhibition.

The Institution continues to be represented on the Permanent Organizing Committee of this Congress by its President and Secretary. The next congress is to be held at the Agricultural Hall, London, in November, 1925. One session is to be devoted to gas engineering, under the auspices of the Institution. A paper will then be read by Mr. C. S. Shapley, of Leeds, on "Public Lighting by Gas with Special Reference to Automatic Systems;" and another on "The Rating of Gas Undertakings," by Mr. George Evetts, of Westminster. Discussions will follow.

Royal Sanitary Institute.

Mr. R. E. Gibson and Mr. H. E. Stone represented the Institution at the congress of the Royal Sanitary Institute which was held at Liverpool from July 14 to 19, 1924.

Smoke Abatement League of Great Britain.

Recognizing the valuable work which is being accomplished by the Smoke Abatement League of Great Britain, the Council have made arrangements for the Institution to become an affiliated member of the League.

Education Scheme.

The report of the Advisory Committee on Education will be presented at the annual meeting. It indicates that satisfactory progress is being made in this important department of the Institution's work.

Refractories.

During the year the Joint Committee of the Institution and the Society of British Gas Industries has had the Standard Specification under revision. Amendments and additions are being completed for insertion in it. The Committee's report for presentation at the annual meeting of the Institution is now in course of preparation.

Mr. A. E. Broadberry having resigned from the Committee, of which he was the Chairman, Mr. J. P. Leather has been appointed in his place. The Council wish to record their sense of high appreciation of the valuable services rendered by Mr. Broadberry in assisting the work of the Committee during the period of his connection with it.

Gas Investigation Committee.

The work of this Committee and of its Research Sub-Committee has been continued partly in a laboratory provided by the Leeds Gas Department at the Meadow Lane Gas-Works, and partly on the new Corbet Woodall Experimental Gas Plant now attached to the Coal Gas and Fuel Industries Department at the University, Leeds.

The principal work in one branch, to which Mr. J. W. Wood has given his time, has been the continuation and development of those studies in the aeration of burners by injection which have already formed the subject matter of the Ninth and Eleventh Reports. The special subject of the year has been the investigation of lighting burners. In addition, careful work has been carried out in order to place the experimental determination of the specific gravity of gas on a better footing. The results obtained are embodied in the Thirteenth Report of the Committee.

Dr. Parker has been occupied in getting the Corbet Woodall Experimental Gas Plant into a proper condition for the carry-out of reliable work by its use and in the making of preliminary tests. It has been thought advisable to embody in the Fourteenth Report a complete description of the plant and its use, the constructions adopted, and difficulties encountered.

The Committee would like to acknowledge its indebtedness again to Mr. J. W. Wood and Dr. A. Parker, the Research Chemists in charge of the two branches of its work now reported upon, for the continuing zeal, ability, and initiative which they have brought to bear upon the work committed to them, with the valuable aid rendered by Mr. Howarth as assistant to Mr. Wood and by Mr. Kerr and Dr. Monkhouse as assistants to Dr. Parker. The opportunity is also taken of thanking Mr. C. S. Shapley and the Leeds Corporation Gas Department for the greatly appreciated facilities which they have continued to provide at the Meadow Lane Gas-Works.

Advisory Committee on the Livesey Professorship.

An arrangement was made this year by which this Committee and the Gas Investigation Committee were summoned for the same day, May 21, 1925, to meetings at Leeds, in order that members of the two Committees should meet one another

and have opportunities for inspecting the work of the Department both in research and teaching.

Prof. Cobb reported that research work had been active during the year, and that one addition had been made to the staff in the person of Mr. Geoffrey Claxton, M.Sc., who has been appointed to assist Mr. J. H. Hoffert, Chief Research Chemist of the Joint Benzole Research Committee of the University and the National Benzole Association. Research publications of the Department during the year include the reports of the Gas Investigation Committee (see above), of the Benzole Research Committee on the use of active carbon and silica gel for benzole recovery, and publications on the subjects of refractory materials and metallurgy.

As regards teaching, the normal day courses have been given, while the special evening lectures were given by Mr. Stephen Lacey, on the "Principles of Gas Distribution," Mr. C. F. Finn, on "Coke Oven Practice," and others. Students have assisted during test periods on the Corbet Woodall Experimental Plant.

Institution Gas Research Fellowship.

This appointment was resigned by Dr. Pexton on his appointment to the research staff of the Gas Light and Coke Company, and he has been succeeded by Mr. C. B. Marson (B.Sc., 1st Class Honours, Fuel and Metallurgy). During the past year Mr. Marson has been engaged upon the study of the influence exerted by the incombustible mineral matter of coal on the processes of carbonization and gasification with special reference to nitrogen and sulphur. The results obtained will be reported to the Institution at the annual meeting in the form of a joint paper by Mr. Marson and Prof. Cobb.

Corbet Woodall Scholarship.

Mr. A. G. Grant continues to hold this scholarship, and will be going up for his final pass Degree Examination for the B.Sc. in Gas Engineering in June. When the Pass Course is completed, Mr. Grant proposes to stay for a fourth year at the University, in order to undertake some research under supervision and present a thesis upon it for the Honours Degree.

Appointments Register.

The Council have instituted a register for the benefit of those members of the Institution who may be out of employment. The District Associations have been informed of the arrangement, and the ready manner in which they have promised to co-operate in the matter is much appreciated. Any members in a position to advise the Secretary of vacancies which are likely to arise are asked to send particulars to the office as soon as possible.

Library.

The donations to the library which have been received during the year are enumerated in an appendix. The Council gladly avail themselves of this opportunity of acknowledging the indebtedness of the Institution to those who have kindly presented them. The preparation of a new edition of the library catalogue is now in hand.

Accounts.

There is also appended a copy of the accounts for the year ended Dec. 31, 1924, duly certified by the Auditors (Mr. Sydney Y. Shoubridge and Messrs. Wood, Drew, & Co.).

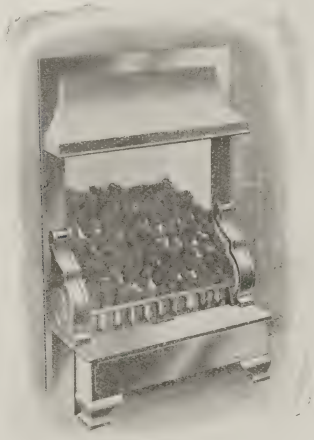
J. Ferguson Bell, *President*
Walter T. Dunn, *Secretary*.

May 22, 1925.

"SENTRY" GAS FIRES.

Readers of the "Journal" will be interested to learn that the manufacturers and patentees of the "Sentry" hot water boilers (Messrs. Wood, Russell & Co., of Nos. 34 and 36, Oxford Street, London, W. 1) have turned their attention to the production of a gas fire which has many attractive features, and of which three types—inset, self-contained, and dog grate—have been placed on the market.

The "Sentry" inset fire should make a ready appeal to those who now have coal grates fitted in their houses, and are potential users of a gas fire embodying in a large degree the charm of the traditional coal grate, and who are at last realizing the enormous amount of labour, dirt, and dust created by burning coal. Great care has been taken to give the fire true architectural expression; and every consideration has been given to designing an efficient, hygienic, and silent burning fire which appears to be a component part of the existing grate.



"Sentry" Inset Fire.

The same fire unit in all its sizes is used for the "self-contained" type; the frame and canopy being designed in the decorative style of the William and Mary period, which lends a graceful and dignified effect. The frame projects only 1¼ in. from the face of the surround. Thus the self-contained fire has the appearance of a built-in model, and is easily fixed by a fitter, without the assistance of other skilled tradesmen. The canopy contains an ample hood for the removal of the products of combustion, and at the same time affords efficient ventilation of the apartment.

The dog grate is made in the 18-in. size, and is fitted with an iron fireback of the "Sussex" type. It is designed expressly to fit into existing tile and brick recesses where the other types of fire would not be suitable.

"Sentry" Self-Contained Fire.

An important feature of the whole series of "Sentry" fires is that the measurement representing the size of fire is the actual width across the radiants. Thus, a 14-in. fire fits the ordinary 14-in. coal grate and is actually 14 in. across the radiants; there being no unnecessary thickness of the firebrick cheeks to give apparent increased width.

A unique feature of the "Sentry" is the introduction of a radiant combining the advantages of the vertical radiant with the charm of the loose black fuel. While an inclined pattern of fire can obviously be made more nearly to resemble a coal fire, this has hitherto been effected at the expense of direct radiant heat. In the "Sentry" fire, however, the lower and vertical portion of the radiant is unobstructed, and direct radiation is assisted by a highly-polished trivet and fuel bar.

Messrs. Wood, Russell & Co. have recently opened extensive showrooms at the address given above, where the new series of "Sentry" fires are displayed in attractive mantel settings. The decoration and reconstruction of the showrooms has been designed by Major F. Cornelius Wheeler, who was Manager of the Nautilus Fire Company before going into partnership with Messrs. Wood, Russell & Co. All interested in the recent developments in coke and gas apparatus should make a point of visiting the showrooms.

NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.

Auxiliary Section Meeting.

The Twelfth Half-Yearly Auxiliary Meeting of the Association was held on Saturday, May 23, in the chemistry laboratory of the Armstrong College, Newcastle. Dr. GEOFFREY WEYMAN, Chief Chemist to the Newcastle and Gateshead Gas Company, presided over a good attendance.

The Chairman, in opening the proceedings, thanked the members for the honour they had done him in electing him Chairman for the current year.

ADDRESS.

By Dr. GEOFFREY WEYMAN.

While the saying that "it is a poor workman who blames his tools" often contains a good deal of truth, yet it is wise periodically to examine our tools to see if they are really capable of doing their proper part. The tools of the gas technician consist of plants of very varied types, and have to deal with a large variety of materials, including solids, liquids, and gases. In making a hurried review of these tools, I am taking up the attitude of the lazy workman who is finding all the faults he has heard of in the particular implement he is supposed to be wielding, not so much as regards the strength or endurance of his tool as in the efficiency with which he can use it.

Far too much of the plant seen in operation is a more or less confused tangle of pipework, tanks, and units of various types. Many of the chief means of control are in almost inaccessible places. The operators are unnecessarily large in number, and have to exert themselves physically to an unjustifiable extent. Those in charge realize only too well what it means to work a badly-designed and ill-arranged plant; and it behoves us to consider seriously how this defect can be avoided. Most plants are now largely designed and erected by firms who make the different units. These plant makers are naturally anxious to standardize their products as far as possible, and are chary of accommodating their designs to suit local conditions. But, to give the best results, plants must be adapted to local conditions; for it is a fact that identical plants may give varying results in different situations, not only so far as general economy goes, but even in regard to efficiency. Plant makers must necessarily obtain their experience of large-scale working at the user's expense; and, when once a plant has been evolved and placed on the market, they too often lose touch with the small details which contribute so much to successful results. The only party really in a position to appreciate the problem and formulate an economical plant is the user himself. The guarantees so often insisted upon are after all only a paper safeguard. A penalty may be enforced for some loss of efficiency, but no plant maker can or will give any assurance against uneconomical working. It is, of course, the economy which counts—the relation of costs to value of output—and as often as not it pays to sacrifice efficiency in some direction for the sake of economy. The plant user has, in fact, to face the responsibility in any case, and must decide for himself which type of plant will work best under his particular local conditions.

In recent years the education and training of technical staffs both in the gas and other industries has so greatly improved, that there is no adequate reason why the design and arrangement of all plant should not be systematically considered, and the plant makers given the necessary plans and specifications enable them to put forward a product suitable in design and convenient in arrangement for each particular set of conditions.

To plan successfully requires imagination. The faculty of greatest importance is that of visualization; the power of forming mental pictures, not only to "see through a brick wall," or more commonly an iron plate, and to picture the other side, but also to form moving pictures in which the various parts of the plant or apparatus are actually functioning as in practice. Many plants would certainly not be in existence to-day if the designers had only visualized them in operation, had realized the effect on the plant when it was overloaded or underloaded, and had seen the operators working under adverse conditions. The final drawings of any proposed plant should most certainly emphasize the position of the controls and the sphere of each workman to be engaged.

An important point to be considered is the amount of capital justified. The expenditure of either too much or too little capital places a severe handicap on the plant. This expenditure will depend on the capacity of the plant, on the system of operation, and on local circumstances. A portion will be devoted to labour-saving arrangements, and another portion to plant for saving materials, including steam and water. The expenditure in each of these directions must be considered if the real economical limit is to be fixed. It is necessary that the capacity of the plant shall have a close relation to that normally required. With a given plant the labour costs, repair and maintenance, and capital charges tend to remain the same whatever the output may be. Even the material charges are sometimes heavier for an under-worked plant. In gas-works most of the plant is subject to a variable load, and this is a great handicap. In many cases variations can be overcome by storage accommodation, and if plant of the continuous type—for example, sulphate plant—is worked only at intervals. The trouble of course is that labour is difficult to absorb in the "off" periods, and the capital and a portion of the repair and maintenance charges are running-on while the plant is standing idle. An alternative is to use smaller plant units, in which case the capital cost per unit of production will be higher and the labour costs also increased. Apart from other considerations, some units of plant—for example, heat interchangers—cannot be worked efficiently at much higher or lower than a definite capacity. Other types do not suffer to any great extent, and a compromise is often advisable, in which certain units are installed of high capacity and worked intermittently, while the rest are worked continuously on a smaller but definite load.

Another consideration is the effect of working losses of materials; and for this reason it may be best to keep the capacity on the high side and use the units less frequently. An example of this is the acid washer of a benzole-refining plant. A further consideration lies in the possibility of future increase in production. Unless the future increase is very definite, it is not advisable to risk incurring increased costs and capital outlay in designing a plant of such a capacity as to absorb this increase. A better plan is to compromise in the installation of large units in those instances where the efficiency is not interfered with, and to allow for duplication of units in other cases.

The system of operation may be either continuous or intermittent. The continuous system has the advantages of lower capital charges per unit of production per day, and lower depreciation charges. There is also less loss of material, and the wear and tear of the plant is smaller by reason of the elimination of the strain of starting and stopping. On the other hand, labour costs are at a higher level owing to the extra cost of shift work, and there is some loss of efficiency owing to poorer control on the night shift. Some operations do not lend themselves to continuous working—for example, rectification for pure products by distillation. In a general sense the continuous system is preferable for the production of crude products, especially if the concentration is low, and intermittent working for the last stages of refinement.

In regard to labour, one point might be emphasized; and that is, that, as replacement of men by mechanical appliances proceeds, the remainder have to be more skilled and more highly paid. The replacement becomes much less profitable as it proceeds; in other words, the capital needed to replace a workman increases very rapidly. The first step might cost about £1500; the second well over £2000.

As an example of local conditions affecting the design of plant, there might be instanced the need of some means of heating purifiers in exposed places on the North-East Coast, as compared with the absence of such necessity in sheltered positions in other parts of the country. A more important instance is the design of retorts situated on this coalfield as against that of plants placed in the Yorkshire coalfield. Distinction must also be drawn between units which are affected by exposure to the atmosphere and others which it is imperative to house.

The materials form a most important item in costs, often amounting to three-quarters of the whole; and considerable expenditure is justified to effect a reduction either by way of lowering the first cost of material or of increasing the efficiency with which materials are handled and used.

In considering plant for process work, it is useful to classify it according to the prime object in each case. There are three main classes—the preparation plant, reaction plant, and separation plant. A subsidiary class can be called "interconnection plant." In the preparation plant the materials are brought into the best physical condition—into a sufficiently concentrated form and under suitable degrees of temperature and pressure. The materials are then in a fit state for chemical reaction.

The reaction plant, which must necessarily be carefully controlled to give really economical working, can be made fairly simple if proper attention is given to the preparation plant. The products of reaction are then dealt with in the separation plant, which separates the various products, and refines or brings them to suitable physical state and concentration for the market. In many cases the separation plant follows on similar lines to the preparation plant, but is usually of a smaller capacity and more delicate in operation. It should certainly be at least as efficient, as it deals with the raw materials on which money has been spent and the value of which is approaching that of the final product. In a sense it is more important than the separation plant, because of the enormous difference in value which occurs in the last stages of refining.

The development of plant for process work largely consists in the extension of the preparation and separation plant, in order that the work of the reaction plant may be simplified and this part of the plant brought under better control. The first form of plant evolved is often a large and clumsy unit, in which materials are more or less mixed up to give contact, and the products roughly separated at the same time. As the process develops, additional units are specially designed and added to prepare the materials or separate the products while the reaction plant is reduced in size. As each unit now has a particular object, it can obviously be made more efficient.

Let us follow this line of thought for a moment, and see what it suggests in regard to gas-works plant.

Carbonizing Plant.—It is unfortunately the fact that the only preparation plant for coal in use on gas-works consists of a coal breaker to reduce the size of large pieces. So far as this is concerned, the important point is that no additional dust should be made, and it is preferable therefore to screen the small coal out, and only send the large to the breaker. So much depends on the treatment of coal prior to carbonization that it seems a pity that the screening, picking, and washing plants are all situated out of control of the gas-works. A point to which insufficient attention has been directed is towards securing uniformity of the chief raw material. There is no doubt that a considerable proportion of capital ought to be devoted to this object, as real economy cannot be secured in the retort house if the coal used is varying from retort to retort and from hour to hour. Again, in view of recent investigations, the inclusion of blending plant for properly mixing-in coke breeze or non-caking materials must be considered.

Reaction Plant.—The retort proper forms the reaction plant, and needs to be designed for the particular coals to be dealt with, and for the type of product resulting from it. We have no control over the coal once it is charged, except to a limited extent in continuous vertical retorts, so that practically everything hinges on the state of the coal prior to charging. It seems to me probable that the various differences in opinion which exist as regards the best size and shape of retorts to employ have arisen owing to the variation in coal used by the respective experts.

Separation Plant.—This consists of condensers, scrubbers, and purifiers. The condenser separates the tar and liquor from the gas, and incidentally withdraws heat from the gas. The question at once arises, How can this heat be utilized? In the days of intrinsic illuminating power the water-cooled condenser was not suitable, because the sudden chilling robbed the gas of a considerable proportion of its candle-power. To-day this condition is somewhat altered, as the reduction in calorific value by this means is not nearly so great. With the atmospheric cooler the heat cannot be recovered, but with the water-cooled condenser it can. The latter then becomes a heat-interchanger, and must be designed for that purpose. Usually the heat interchange is effected between the gas and boiler feed water, but it is a moot point whether the heat could not be more usefully employed at the purifiers—being transferred, either by a double interchange or by using the cold gas as the cooling medium in the condensers, before the purifiers.

Scrubbing Plant.—The scrubbing plant can be considered as a plant in itself—the scrubber or washer being the reaction unit; the condensers and tar extractors, the preparation plant, and the storage wells the separation plant. The object here is to produce a liquor of maximum strength and to recover all the ammonia. The essentials are low temperature, sufficient time contact, and a true counter-current system. Unless adequate condenser and tar extracting units are available, the scrubbers and washers will have to be greatly extended in size, because you cannot get proper contact when tar is present. In fact, as the scrubbing plant is reduced from sets of large tower scrubbers to the equally efficient but smaller and more delicate centrifugal washers, so the necessity arises for the more extended and efficient preparation plant, which takes shape in two directions—the purifying of the gas from tar, and of the water from substances which would be precipitated in the reaction vessel. It is, in fact, fatal to use water which has a high temporary hardness in a centrifugal washer if the gas also contains tar. So far as the separation plant is concerned, it is usually conspicuous by its absence, and in some cases cold liquor and hot tar are dumped in the same storage well under conditions which must obviously lead to loss of ammonia and bad separation.

Oxide Purification Plant.—This should be shown the same consideration. In order to reduce the size of the reaction plant—the purifiers—and also the amount of oxide used as a catalyst, it is necessary to use preparation plant for raising the temperature of the gas to that required for rapid reaction, and to bring the oxide used as a catalyst to a suitable physical and chemical state. In both these instances the ordinary gas-works plant can hardly be considered complete; and there would appear to be possibilities, which have not been sufficiently explored, of reducing the size of purifiers to at least one-hundredth of their present size. It is true that in many cases steam-heated coils are used in the boxes, but a little reflection will show the utter incapacity of such coils of reasonable size to influence the temperature of the huge volume of pas passed or the 100 tons or so of oxide enclosed in the metal box. Again, we are faced by the fact that no separation plant is used to concentrate or improve the quality of the spent oxide; and in view of the fact that materials such as pan-ashes of very low value can be economically concentrated, it should not be impossible to separate the mixture of oxide of iron and sulphur in an economic manner.

This short review will indicate the utility and suggestiveness of classifying plant, and how it is possible to arrive at an economic balance between the different portions of a plant.

Finally, there is one very important adjunct of plant which is still much neglected, and that is the means of control and the facilities for control. As development of plant takes place, so the operation becomes more intricate, and so the necessity arises for delicate means of control. If plant is to work with maximum economy, it is essential that we should know both when it reaches this desirable level and also the conditions under which this state of affairs is maintained. To obtain this knowledge, we must have means of measurement of both quality and quantity, besides the means of ascertaining such conditions as temperature and pressure. Really good facilities of control can only be given at the time when plant is designed and erected; and yet how often it is an after-thought! Moreover, the cost of such means, while usually insignificant, ought to be considered in relation to other costs, and reckoned and allowed for in the capital and running costs of the plant. It has always been a wonder to me that makers of plant should allow units which they are anxious should be an economic success to be installed

ARMSTRONG COLLEGE OF SCIENCE.

Art Department on left; Chemical Department on right; tower of new Union in the background.

HYDRAULIC LABORATORY—ENGINEERING DEPARTMENT.

ithout any means whatever of ensuring, by proper control, that ey are so.

There was no discussion.

Mr. L. M. Weldon (West Hartlepool) moved a vote of thanks Dr. Weyman for his address, which, he said, had been pre- ared on broad yet definite lines.

Mr. H. Greig (Sunderland) seconded, and remarked that the aper had given them something to think about. His subject as appropriate in view of the opposition which the gas indus- y had to meet from electricity concerns.

Inspection of Armstrong College.

At the conclusion of the meeting held in the main chemical cture theatre, the visitors proceeded to inspect the labora- ries of the Departments of Chemistry, Engineering, Metal- rgy, and Physics. Mr. Robinson guided the party round the hemical Department, showing first the research laboratory voted to work on the sugars—a particular study of Prof. aworth's. The chemical library is well situated between the boratory and the room in which apparatus mechanically erated is installed. A vacuum dessicator, Langmuir's mer- ry-pump, and a laboratory centrifuge were noted. Here the rty were greeted by the Principal of the College, Sir Theodore orrison. Accompanied by Prof. Haworth the party passed rough the laboratory devoted to organic chemistry and to the hnstone laboratory, a particularly fine and spacious room. A ll-equipped balance room and lecturers' laboratory were ited. It was explained that the laboratories for physical emistry were at present situated in temporary buildings outside the main building. The visitors were interested in a darkened laboratory where work on silver salts is proceeding under the direction of Dr. Briscoe. A particularly sensitive chemical balance was exhibited. A well-fitted glass-blowing room was seen in which all special glass apparatus is made as required. Prof. Haworth said how pleased he had been to welcome the party and to receive fresh proof of the interest in chemistry shown by the many branches of industry.

The party next passed on to the large engineering drawing office, and under the guidance of Mr. Martin were shown the various machines and testing appliances. It was explained that, owing to the installation of a new boiler house, it had become necessary to re-arrange most of the machines, grouping those using steam in a new building next to the boiler house, and replacing most of the other units. Among the numerous machines were noted a Diesel engine, a 100-ton Buckton testing machine, and a Martin-Avery testing machine. The large hydraulic laboratory equipped with different examples of turbines was much admired. The visitors passed on to the new boiler house, where three mechanically stoked Lancashire boilers supply the steam for heating the College buildings. These boilers, like all other plant, are suitably fitted so that the students may make all necessary tests and trials. There were also water-tube boilers in course of erection. In the steam engine section a variable multiple expansion engine and a recently-acquired experimental type of Parsons steam turbine were noted.

Passing on to the Metallurgical Department, the party were received by Dr. Smythe, who had arranged a demonstration

THE JOHNSTONE LABORATORY—CHEMICAL DEPARTMENT.

showing the preparation and etching of metal specimens for microscopic examination. The visitors—and particularly those concerned with the distribution side—were keenly interested in the specimens shown under the microscope illustrating the difference in structure between wrought iron and steel. Several members registered a resolution to develop the metallurgical examination of materials in their works. Owing to the time spent in this direction it was necessary to pass quickly over the other sections of the laboratories where coke-fired muffles and furnaces, for the reduction of ores and preparation of alloys, were grouped. The extension of the Department outside the main building could not be visited. The party were welcomed at the physical lecture theatre by Mr. Lunnon. Consideration for the visitors had led Prof. Stroud and his colleagues to believe that a demonstration of one or two experiments dealing with physical phenomena which have received application in the gas industry would be welcomed more than a cursory inspection of the Herschel laboratory and the range of research laboratories. Mr. Lunnon had therefore arranged in an excellent manner a few experiments which were viewed with marked interest by the members. One of these showed the great difference in the power of diffusion of coal gas and air. Another illustrated the marked difference in the viscosity of hydrogen and oxygen. In a third, coils of platinum wire were heated to the same degree by a similar current of electricity, and were immersed respectively in streams of coal gas and air, when the effects of the different conducting properties of the gases were clearly visible. The visitors were able to see the extreme sensitiveness of an instrument in which changes in the composition of gas causes a movement in the interference colours.

The party concluded the proceedings with tea served in the new Union building recently erected through the generosity of an anonymous donor.

The Chairman proposed a vote of thanks to the Principal of the College, to the Heads of the Departments visited, and to the guides who had shown them round. He said that some fifteen years ago, when he passed through the College, it was certainly the hardest working College in the country. From what they had seen he could believe that it was still so; but he was glad to find that two needs felt very much in his day—playing fields and adequate Union accommodation—had since been filled through the generosity of private individuals. The College had expanded in all directions; but it was tragic to find its work hindered by lack of finances. He felt it ought to be more supported by local industry; and since the gas industry was dependent on coal, he wondered if development might not take place in the direction of some department concerned primarily with the study of the constitution and peculiar properties of coal, for which all the sciences were needed. Their visit that afternoon had been of great use to them; and he felt justified in asking the members not only to support the vote of thanks, but to register a resolve to make the utmost use of the College.

Mr. Copland (Newcastle) seconded, and referred to the development and complexity of modern plant and machinery.

Dr. Smythe, on behalf of the College, thanked the members. The complexity of modern industrial plant had been referred to by Mr. Copland; and he could not see how it was possible for those taking part in industrial life to do without such a training as provided at the Armstrong College.

Petrol for Starting Gas-Engines.—According to the "Engineer," a recent issue of "Vulcan" contains a warning about the use of petrol in starting gas-engines. In the case under review the engine would not start with gas, so some petrol was poured into the air inlet silencer. The engine then started readily and began to race. Shutting the gas inlet valve was of no avail; and an accident was only averted by tearing the ignition wire from the plug. It was found that nearly 2 gallons of petrol had been poured into the silencer; and this provided a large supply of fuel uncontrolled by the governor. When petrol is used, it should only be sprayed into the cylinder in definite small quantities.

Gas to Melt Snow and Ice on Railroads.—An interesting, and perhaps novel, use of gas is recorded by the "Inter-colonial Gas Journal of Canada," which states that some of the steam railroads are using gas to take the place of snow shovellers in freight yards, to keep frogs and switches cleared of snow and ice after heavy storms. The Pennsylvania and Erie Railroads have adopted the gas method for some of their important New Jersey yards. A convenient gas main is tapped, and a line of hose conducts the gas to the switches, where specially designed burners are placed. The burners are clamped between the ties to both rails, and when lighted heat the rails to such a degree that the snow and ice in the area is melted. Each set of burners does as much work as four men could do in the old way. In the Waverley yards of the Pennsylvania Railroad at Newark there are 172 gas burners, which consume 4300 c.ft. of gas per hour. These are connected to the street main at New Jersey Railroad Avenue, Newark, by a pipeline 2000 ft. long. Similar burners are also used in the Trenton yard of the Pennsylvania Railway and in the Rutherford yard of the Erie Railway.

WALES & MONMOUTHSHIRE DISTRICT INSTITUTION OF GAS ENGINEERS AND MANAGERS.

General Meeting at Porthcawl.

So enjoyable proved the meeting held by the Institution at Porthcawl barely two years ago, that it was again decided upon as the place of meeting for the gathering last week; and an attendance of some fifty members proved the wisdom of the choice. Mr. W. H. Johns, of Swansea (the President) was in the chair. In the morning a paper by Mr. H. D. Madden, of Cardiff, was read and fully discussed; and after lunch, a pleasant afternoon was spent in bright sunshine and the invigorating air of the popular South Wales watering place.

The meeting was held in the Council Chamber, and was opened by Mr. Davies (the Vice-Chairman of the Porthcawl Urban District Council), who heartily welcomed the members to the town. He expressed regret at the absence of the Chairman, who was in London.

Minutes of the Last Meeting.

The Hon. Secretary (Mr. Octavius Thomas, of Pentre) read the minutes of the last meeting, and they were confirmed.

The Institution Roll.

On the proposition of Mr. A. E. Davey (Aberdare), seconded by Mr. B. Grainger (Caerphilly), the following additions were made to the roll of the Institution:

Members.

Mr. James Allen Cunniffe, Superintendent, Morriston Gas Works, Swansea.

Mr. Thomas Watson Little, Manager, Gas-Works, Mitcheldean, Glos.

Students.

Mr. John Martin Randell, Swansea.

Mr. Colin Ronald Monroe, Cardiff.

An Honorary Member.

Mr. J. H. Canning (Newport) proposed the election of Mr. R. G. Clarry, M.P., as an honorary member of the Institution. He had a great many friends in the gas industry; and though he was now in Parliament, his interest in the industry was as great as ever.

Mr. H. D. Madden (Cardiff), in seconding, said Mr. Clarry had done much for their Institution, but he was doing even greater work for the whole industry in Parliament, by the Bill he was promoting to give powers to gas companies to provide electricity.

The President remarked that, as Mr. Clarry's successor at Swansea, he would like to support the proposal; and the meeting heartily endorsed it.

Annual Report.

The Hon. Secretary then read the twentieth annual report of the Council, which stated that during the year three members and two students had joined the Institution, and six members and one student had resigned, leaving the number at the end of the year at 72 members, 8 students, and 1 honorary member. The receipts for the year amounted to £79 15s. 6d., and the payments to £75 9s. 8d., leaving, with the balance brought forward from last year, the sum of £43 2s. 2d. in the Treasurer's hands, together with £100 of 2½ p.ct. Consols.

Arrangements are being made to start classes in Gas Engineering and Gas Supply at Cardiff and Swansea during the coming winter, which the Council hope will be taken advantage of.

Mr. E. Ablett (Swansea) proposed the adoption of the report and accounts, remarking that both were very satisfactory.

Mr. H. D. Hazell (Newport) seconded the motion, which was carried.

New Office Bearers.

The following were elected office-bearers for the ensuing year:

President.—Mr. H. D. Madden, of Cardiff.

Junior Vice-President.—Mr. A. T. Kyle, of Abergavenny.

New Members of Council.—Messrs. T. B. Pearson (Pontypool), A. E. Williams (Cardiff), and E. Petty (Hirwain).

Hon. Treasurer.—Mr. J. H. Canning, of Newport.

Hon. Secretary.—Mr. Octavius Thomas, of Pentre.

Hon. Auditors.—Messrs. J. H. Jones (Dowlais), and A. E. Davey (Aberdare).

The President, proposing the election to the chair of Mr. H. D. Madden, of Cardiff, remarked that it was not necessary for him to say much about that gentleman, because they all knew him well and realized that he had always put forward every effort in the best interests of the Institution, and in everything that he undertook on behalf of the industry. He had been their President on a former occasion, and they would be greatly honoured by his becoming so again. It was extremely gratifying to them and to all his many friends to find that he had also been nominated Junior Vice-President of the Institution of Gas Engineers.

Mr. Canning seconded; remarking that they esteemed Mr. Madden, not only for his pre-eminence in everything that per-

ined to his profession, but also for those personal qualities which had endeared him to all of them. Since he had been in hat district, he had done everything possible to help his colleagues, and had made friends everywhere.

Mr. MADDEN thanked the members very much for honouring him by asking him to accept the Presidency for a second ime during the comparatively few years that he had spent mong them.

Mr. H. BARKER (Llanelly) proposed Mr. A. T. Kyle's election s Vice-President; and Mr. W. CLARK JACKSON (Neath) econded—pointing out that Mr. Kyle had been with them a ong time, and had taken an active part in Council matters.

The PRESIDENT proposed Mr. Octavius Thomas's re-election s Hon. Secretary, saying he did not know what they would o if he found it impossible to continue in this and the other ffices he was so ably filling for the industry in that part of the ountry.

Mr. A. T. KYLE (Abergavenny) seconded the motion.

LETTER FROM THE PRESIDENT OF THE INSTITUTION OF GAS ENGINEERS.

The HON. SECRETARY then read the following letter, which ad been received from Mr. J. Ferguson Bell, the President of ie Institution of Gas Engineers:

I regret nearness of the annual meeting of the Institution of Gas Engineers prevents my accepting your very kind invitation to be present at a meeting of your Institution to be held at Porthcawl.

I am very pleased to observe that you propose to elect Mr. R. G. Clarry, M.P., an honorary member, in recognition of his valuable services rendered to your Institution. May I add that Mr. Clarry has given very valuable assistance in many ways to the gas industry?

In addition, I should like to take this opportunity to thank the Wales and Monmouthshire Institution for their support of the Institution of Gas Engineers' Benevolent Fund.

I look forward to the pleasure of seeing a good many of your members at the annual meeting of the Institution of Gas Engineers.

BENEVOLENT FUND OF THE INSTITUTION.

The HON. SECRETARY proposed that a contribution of five aineas should be made to the Benevolent Fund of the Institu- on of Gas Engineers; and he also appealed to those members ho did not do so to subscribe individually. There had been a ry sad case of one of their own members who died sud- nly; and fortunately he (Mr. Thomas) was able to get a sub- antial grant for the widow. More money was wanted; and hoped that members would see what they could do. Even ms of a few shillings would be gratefully received by the In- tution of Gas Engineers.

Mr. J. ROBB (Chepstow) seconded the proposal, and it was reed to.

RULE 2 AMENDED.

Mr. MADDEN moved that Rule 2 of the Institution be altered read:

"That the Institution shall consist of members, honorary members, and students. Members and honorary members shall consist of engineers, managers, assistant engineers or managers, and technical assistants, whose qualifications shall not be less than those involved by the possession of the Higher Certificate of the Institution of Gas Engineers in Gas Engineering or Gas Supply, and who are in the service of gas companies or local authorities. Students to be pupils under the training of Engineers of gas-works in the service of gas companies or local authorities."

pointed out that this meant the opening of the doors of the stitution to those men who could secure the Higher Certificate the Institution of Gas Engineers in either Gas Engineering Gas Supply. He thought the Council had made a right ve in this matter. As one who knew a little of the inside rking of the Education Scheme, he could say that for a hnical assistant to obtain the Higher Certificate was no easy ng. His qualifications must be good before he was allowed sit. The amended rule would be an encouragement to the nger members of the profession to do their best.

The HON. SECRETARY seconded, and pointed out that the pro- al would only apply to future members.

A MEMBER'S RETURN.

The PRESIDENT said they had with them one of their mem- s, Mr. William Collin, who had spent some time in Chili— Coquimbo and Talcahuano. They were all very pleased to e him with them once again.

GENERAL SALES PROPAGANDA.

Mr. MADDEN then read a paper on "General Sales Propa- nda," which, with a report of the discussion, will be pub- ied next week.

Before the meeting closed, a vote of thanks to the Chairman d members of the Porthcawl Urban District Council, for ir kindness in granting the Institution the use of the Coun- Chamber, was passed on the proposition of Mr. JACKSON, nded by Mr. BARKER.

cknowledgment was made by Mr. F. JAMES (the Chairman he Gas Committee).

he members then had lunch together in the Pier Hotel, r which Mr. Madden submitted the toast of "The Porthcawl Urban District Council," coupling with it the name of Mr. James, who responded. Councillor GRIFFIN proposed "The Wales and Monmouthshire District Institution of Gas Engineers and Managers," remarking upon the indebtedness of the Porthcawl gas undertaking to both the Institution and Mr. Thomas. The President, in his reply, emphasized the many advantages possessed by combined gas and electricity undertakings.

CHEMICAL ENGINEERING GROUP.

Annual General Meeting.

The Annual General Meeting of the Chemical Engineering Group of the Society of Chemical Industry was held at the Chemical Industry Club, Whitehall Court, London, on Friday, May 29, and was preceded by an informal dinner, at which Mr. W. J. U. Woolcock, C.B.E. (President of the Society of Chemical Industry), was entertained. Mr. C. S. Garland (Chairman of the Group) presided.

The report of the Committee of the Group, which was unanimously adopted, recorded that the year's work had been carried on with noteworthy success, and that even better results are anticipated in 1925. Membership has increased from 315 in 1922 to 408 in 1924.

It has been the policy of the Group to co-operate with the various sections of the Society of Chemical Industry, and with other scientific institutions, in the holding of joint meetings, in addition to its own meetings; and this policy is to be adhered to in the future. There were a number of joint meetings held in 1924 in London and the Provinces, all of which were well attended, and provoked interesting discussions. The relations between the Group and the parent Society continue to be most cordial, and the Group is working in close co-operation with the Institution of Chemical Engineers in matters affecting their joint interests. At the Conference of the Smoke Abatement League at Manchester, in November, 1924, the Group was officially represented.

Attention was given in the report to the World Power Conference, held at Wembley from June 30 to July 12 last year, the Chemistry and Physics Section of which was organized by the Group at the request of the Society of Chemical Industry, and under the *ægis* of the British Electrical and Allied Manufacturers' Association. It was stated also that the Gas and Fuel Section of the Conference, which was organized by the National Gas Council, developed from the initial work of the Group Committee.

Reporting Accidents with Gas.

The Pacific Coast Gas Association have been taking pains to investigate accidents occurring with gas. During the eight months beginning with last August, an account was kept of reports appearing in the Daily Press of accidents to the public with gas in all Pacific Coast States; and the Secretary, realizing that the haste with which newspapers prepare their copy often leads to inaccuracy, attempted to verify the statements appearing in the Press. A letter was written to the gas company upon whose district an accident had been recorded, requesting the results of any investigation that might have been made, in order that this could be compared with the newspaper statement. Out of 31 replies containing sufficient detail to permit of a definite conclusion being reached, the significant facts emerge that in only six of the cases was the accident reported with reasonable accuracy by the Press; and that in ten instances the report was entirely incorrect, and gas either had nothing whatever to do with the accident, or was merely an "accessory after the fact."

Refining of Crude Tar Oils.

Abstracting an article from the "Technische Blaetter," on the subject of the refining of crude tar oils, the "Bulletin of the Cleveland Scientific and Technical Institution" says that these oils, especially the high boiling-point fractions, have a tendency to darken in storage, which unfits them for many purposes. Purification with sulphuric acid, as is common practice in the petroleum industry, will not do in this case, neither will liquid sulphur dioxide, although aqueous sulphuric acid is employable. It has now been found that these oils—and particularly such of their fractions as boil at over 200° C.—can be purified or refined by treating with alkalies or alkaline media. For this purpose they are mixed with small quantities of solid alkalies; heated with return-condensation; and then distilled-off from the residue. This process loses very little oil, and uses only a small quantity of purifier—the greater part of which can be regenerated. The advantages as against the aqueous sulphuric acid method are that the process can be carried out in any kind of iron vessel, and that it is speedy. It is suitable for purifying neutral as well as acid oils, and also unseparated mixtures of same such as occur in tar distillation. The process is covered by a German patent.

ABERDEEN GAS-WORKS.

Official Inspection.

On Monday, May 25, an official inspection of the works of the Aberdeen Corporation Gas Department was made. To mark the occasion, an illustrated brochure, descriptive of the undertaking, was prepared, from which we take the following few extracts.

Historical.

The Aberdeen Gas Light Company came into being in the year 1824. During the first four years of the Company's life only oil gas was manufactured, and the price charged was from 50s. to 40s. per 1000 c.ft. In 1828, the Company dropped the use of oil, and commenced the manufacture of coal gas, when the price of gas immediately fell to 15s. per 1000 c.ft. The success of the original Company led, in the year 1844, to the formation of a competitor, the Aberdeen New Gas Light Company, who erected their works at Sandilands, on land which now forms part of the present gas-works. Gas at this time was charged at 9s. per 1000 c.ft. It was soon discovered that it would be expedient to amalgamate the two Companies; and this amalgamation took place in 1846, when the manufacturing operations were concentrated at the Sandilands site. In 1871 the Gas Company's undertaking was transferred by Act of Parliament to the Town Council of Aberdeen. Gas at this time was 5s. 5d. per 1000 c.ft.

The remarkable progress of the undertaking since the date of transfer may be seen from the following table:

Table Showing Progress of the Undertaking During the Last Fifty Years.

	Gas Made. C.Ft.	Gas Rental.	Residual Products.	Price per 1000 C.Ft.	
			£	s.	d.
1874	172,171,000	36,074	2,911	5	0
1884	286,770,000	47,590	7,986	3	10
1894	430,569,000	65,440	11,011	3	5
1904	649,049,000	93,974	21,090	3	0
1914	989,598,000	107,235	39,493	2	3
1924	1,440,715,000	166,131	87,026	2	6

The Sandilands site occupies an area of 9¼ acres, while the gas storage site, situated about half-a-mile distant, extends to 4½ acres.

The gas-works are about three-quarters of a mile from the Railway Station, but are connected by a railway with the various yards and the harbour—Corporation locomotives being employed to handle the traffic.

Carbonizing Plant.

The carbonizing plant now consists of 432 horizontal retorts arranged in beds of eight, and comprising four benches, operated by mechanical stokers, and two installations of Woodall-Duckham vertical retorts—the latter having a total carbonizing capacity of 292 tons of coal per 24 hours.

In 1899 and 1901, inclined retorts were erected by way of experiment. These retorts, 36 in number, were put out of action in 1923, to make way for the second installation of verticals. In 1908 a carburetted water gas plant was installed, comprising two sets of Merrifield-Westcott-Pearson type; each set being capable of producing 750,000 c.ft. of C.W.G. per diem.

In 1913 a contract was placed with the Woodall-Duckham Vertical Retort and Oven Construction Company (1920), Ltd., for a carbonizing plant of 100 tons capacity per day, consisting of twenty Woodall-Duckham vertical retorts built in settings of four. This plant has now been in operation for eleven years. It continued for eight years without being re-set, and then only partial re-setting was necessary. As the result of the success of this first plant, the Gas Committee and their Engineer and Manager, Mr. S. Milne, decided to scrap the inclined retorts, and to replace them with verticals. A contract was therefore placed, in June, 1923, for a further installation of Woodall-Duckham verticals having a capacity of 192 tons per 24 hours; and this plant was put to work at the end of November, 1924.

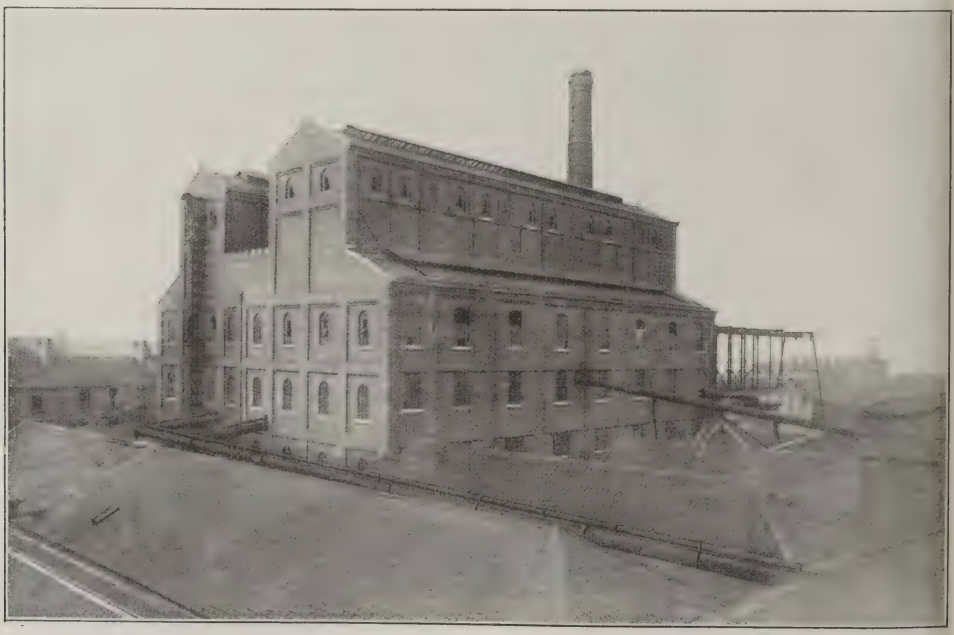
The new plant consists of twenty-four retorts built in settings of four. In comparison with the first installation, it is interesting to note that, per ton carbonized per day, there is a saving of ground space amounting to at least 25 p.ct.

A waste-heat boiler of the Woodall-Duckham fire-tube type has been provided; and when all the retorts are working at full capacity, the boiler is capable of generating 4200 lbs. of steam per hour at 100 lbs. per sq. in., from feed water at 60° Fahr. To ensure that steam used for steaming the retorts is absolutely dry, a superheater is provided in the inlet flue to the boiler, capable of raising the temperature of the steam to about 500° Fahr. In order to provide sufficient pull on the settings, an induced draught fan is provided at the outlet of the boiler, driven by a high-speed vertical steam engine. The feed water is heated by means of the exhaust steam from this engine.

Outstanding Features.

The outstanding features in connection with the new plant at Aberdeen which show the trend of improvements in vertical retort design may be summarized as follows:

1. Large units, working independently of each other, which can be regulated individually and shut down for scurfing or repairs without causing any interference with the remaining working retorts. The labour required to work the plant is the same per unit as that necessary for



WOODALL-DUCKHAM VERTICAL RETORT HOUSE.
Showing 1913 settings on left, and 1924 settings on right.

Producer Stage.

Conveying Plant.

smaller units, and thus considerably reduces the working costs.

2. The regulation of the temperatures in the combustion chambers is particularly easy, due to the ample area of all flues and the reserve capacity of the producers, and it is found possible to work the plant over long periods without making any adjustment whatever to the controlling dampers which are provided for the independent chambers of each retort.
3. The plant is worked under a very low draught; and thus infiltration of air into the waste gas flue is reduced to a negligible quantity, with the consequent saving of power for the induced draught fan of the waste-heat boiler.
4. The producers are of large capacity, and their particular feature lies in the fact that they will carry a reserve of fuel to last for 24 hours without unsealing their curtain arches.
5. The extractor gear is so silent that the Engineer has installed an indicator at the top of the setting level, so as to inform the top man should any stoppage occur to the extractor driving engine, or its stand-by motor.
6. The combustion chambers can be inspected at the top and the bottom in comfort; the sighting holes being readily accessible. Thus a complete set of temperatures can be quickly obtained.
7. The plant is particularly cool, both on the charging stage and on the damper control platform, due to the special attention that has been paid to the insulation of the outside walls on the top setting brickwork.

BRITISH COMMERCIAL GAS ASSOCIATION.

DISTRICT CONFERENCE AT HARROGATE.

A DISTRICT Conference under the auspices of the British Commercial Gas Association was held at Harrogate, on May 21; the meeting taking place at the Harlow Manor Hydro. The proceedings opened by a luncheon, at which about eighty were present. The subsequent conference was held in the delightful Winter Garden of the Hydro—fitting surroundings for discussion of the advantages of gas as a means of restoring to the public the benefits of sunlight, natural beauty, health, and cleanliness.

Mr. Francis Barber, Chairman of the Harrogate Gas Company, presided over all the proceedings of the day. At luncheon he was supported at the top table by the Mayor of Harrogate (Councillor C. E. Carter, J.P.), the Mayor of Halifax (Alderman J. H. Waddington, J.P.), the Town Clerk of Harrogate (Mr. Turner Taylor), Mr. J. H. Ellis (President of the "B.C.G.A."), Mr. A. Proctor (Chairman of the York Gas Company), Dr. R. Veitch Clark, M.A., M.B. (Medical Officer of Health for Manchester), Dr. James Mair, M.B., D.P.H. (Medical Officer of Health for Harrogate), Mr. F. H. Robinson, Assoc.M.Inst.C.E. (Engineer and General Manager of the Harrogate Gas Company, and President of the Manchester District Institution of Gas Engineers), and Mr. W. M. Mason (Manager of the "B.C.G.A.").

The first toast, following that of "The King," was to "The Prosperity of Harrogate," which was proposed by Alderman WADDINGTON in a characteristic speech, and replied to by Mr. CARTER.

PROBLEMS OF THE GAS INDUSTRY.

Mr. ALFRED PROCTOR, proposing a toast to the "B.C.G.A.," said he believed it was generally recognized to-day in the gas industry that, without the wonderful help of the Association, the industry would be much worse off. He was present at the inaugural meeting thirteen years ago, when Sir Corbet Woodall was the first President. He believed that Sir Corbet's prophecy that the "B.C.G.A." had heralded-in a new world for the gas industry had been amply fulfilled. For a long time now the trend of opinion had been in the direction of common action in the industry. The efforts of local undertakings could have little general success without the central organization of the "B.C.G.A." The question of the residuals market was very much in mind at the moment. They all knew the seriously adverse conditions of that market—conditions which had been reflected in almost every undertaking's balance-sheet for 1924. Nothing could be accomplished in this matter by local effort; but a strong central committee were considering the question, and they all hoped their work would tend in some degree to relieve the industry from the present adverse conditions. Another important subject demanding attention was the strenuous competition of the electricity industry. He believed gas was to be met by more intensive competition than ever before. The production and distribution of electricity was to be backed by the resources of the State. If the State considered it necessary to subsidize electricity, then he claimed that the gas industry should have the same treatment. The growth in consumption of gas, which was the universal experience of undertakings in 1924, was due in no small measure to the work of the "B.C.G.A." Results had shown that gas as a commodity for domestic and trade uses was growing strongly in popular favour. The industry had completed a century of gas supply. If one looked back on its history, one must be impressed by the extraordinary buoyancy and elasticity to changing conditions. The industry came to birth in a cloud of ridicule, and there had since been many crises. The competition of electricity had not extinguished the gas industry. On the contrary, it had been a great stimulus. One feature in the aims and ideals of the "B.C.G.A." which he would emphasize, and one which was consistently enlarged upon by Mr. F. W. Goodenough in his energetic work for the movement, was the ideal of public service. They must all recognize—whether municipal administrators or company controllers—that they were ministering very greatly to the daily needs and comforts of the people among whom they lived.

Mr. J. H. ELLIS, responding to the toast, said that the greatest object of the "B.C.G.A." was to publish the truth. The Association stood for clean and comfortable homes, for clean and comfortable towns, for cheapness and efficiency in industry; and he did not care what rival they had to face, provided the competition was fair. He had in his time been interested in both the electricity and the gas industries. What he said was: Let each be used where it is most economical and efficient. What they objected to was unfair competition; and they looked like getting it in the grossly unfair proposition to bolster up one industry with money wrung from the taxpayers, and at the expense of another industry. The gas industry had its exhibit at Wembley, and was appealing for support to gas undertakings, because it knew that bread cast upon the waters at Wembley would be returned a hundredfold.

PROGRESS AND PROSPERITY.

Mr. W. M. MASON, proposing a toast to the Chairman and Directors of the Harrogate Gas Company, read a telegram of greeting from Mr. F. W. Goodenough, Chairman of the Executive of the "B.C.G.A.," who wired: "To-day's 'Times,' 'Telegraph,' 'Morning Post,' and others show activity of Headquarters. Association's influence was very helpful in securing results. All good wishes." He (Mr. Mason) was sure all wished the Chairman and Directors of the Harrogate Gas Company success and prosperity. Prosperity was not merely a thing to drink to. It carried other aspects. The biggest

thing in prosperity was progress. The Harrogate Gas Company were making efficient progress. He was afraid the great public service rendered by the gas industry was often forgotten by the public who benefited from it. It would be remembered quickly enough if the service which had been enjoyed for generations, and which he was confident would be enjoyed for generations to come, was suddenly stopped. The greatest national festival in England was not the "Derby" or the football Cup Final. It was the Sunday dinner in every home in the country; at which period the gas industry was putting out more gas than at any time in the whole of the week. This showed how the public benefited by the gas industry.

AN ENTERPRISING UNDERTAKING.

Mr. FRANCIS BARBER, replying, gave an outline of the history of the Harrogate undertaking. He suggested that the record of service rendered by the public utility undertakings of this country, and particularly the gas undertakings, would always be worthy of the highest commendation. The Harrogate Gas Company not only supplied gas, but saw to it that the consumer got the best service from it. The undertaking had now 90 miles of mains, and they had an Order for taking-over the small undertaking at Pateley Bridge, twelve miles away, and including the area of that works in the Harrogate area of supply. They had at present 10,900 consumers, using over 20,000 gas appliances; and recent sales of apparatus had averaged about 2000 a year. They had a co-partnership scheme by which the workers enjoyed a share of the profits of the undertaking; and they were hoping shortly to arrange a superannuation scheme for the benefit of the aged or incapacitated.

THE CONFERENCE.

CHAIRMAN'S OUTLOOK.

At the opening of the afternoon conference, Mr. MASON read a letter from Mr. F. W. Goodenough, Chairman of the Executive, regretting his unexpected inability to be present.

The MAYOR OF HARROGATE gave a brief but hearty welcome to the conference, and mentioned that the gathering was one of a series of conferences which it was expected to hold at Harrogate during the present summer.

Mr. FRANCIS BARBER, in his opening remarks as Chairman of the meeting, said he was proud to give what support he could to the "B.C.G.A." It was his privilege to be present at the inaugural meeting of the Association, held in Manchester in October, 1912, under the presidency of Sir Corbet Woodall, whose name and work must always have a place in its history. The meeting left on his mind an impression of the erection of a massive structure in unity to be sustained by pillars which would not only maintain it against all attacks, but be strengthened by every attempt to shake it. He was glad to know his expectations had been fully realized. They must not forget, however, that the life and soul of the Association would always depend on the inspiration and the activities of those at its head. He wished to take the opportunity of bearing his personal testimony to those to whom they owed so much; and he hoped he was not out of place in singling out Mr. F. W. Goodenough as the very heart and inspiration of the movement, and Mr. W. M. Mason as its clever administrative head. It was a real personal disappointment to have been deprived at the eleventh hour of Mr. Goodenough's presence that day.

He believed the advantages the industry had gained by the work of the "B.C.G.A." had repaid with abundant interest the financial contributions the Association had received from the supporting undertakings; and he appealed to every concern outside the Association to make their proper contribution to the cost of the work from which they, like all others, were receiving so great a benefit. If they were called upon to fight so unjust a preference as that proposed to be given to electricity undertakings, it was necessary that the Association should be able to speak for every gas undertaking in the country, great or small.

THE ELECTRICITY SUBSIDY.

Turning to the electric subsidy question, he must express his astonishment that a Government elected on an anti-Socialistic policy should, through the responsible Minister, have declared their adherence to so deliberate a step towards the socialization of an industry as to propose to indemnify it against loss on its development in unremunerative areas. He was surprised that Mr. Philip Snowden, the outstanding apostle of Socialism, should have found so many ready disciples in the Cabinet of the present Government. If any industry was entitled to the generous support of the Government, it was the gas industry, which in the hour of the country's peril rendered service of incalculable value. ["Hear, hear."] They could never forget the mean and contemptible acknowledgment of those services which was embodied in the Statutory Undertakings (Temporary Increase of Charges) Act, 1918, which left the proprietors with so small a return on their invested capital. No industry which did so much in support of its country's cause suffered more. If any preference were given to the electricity industry and were not also conceded to the gas industry, it would not be "cricket;" and he thought it would outrage that spirit of fair play upon which they as Englishmen prided themselves. Mr. Barber said he had for some time been a shareholder of several electricity undertakings, but he was not aware that they had sought the assistance which the Government proposed to give them. He believed they were developing on sound lines, and would be able, by their own resources, to finance all developments likely to be remunerative in ten, fifteen, or twenty years. He did not agree that electricity could bring to the rural districts advantages at all on a par with those to be obtained from gas. The gas industry had, indeed, a much stronger case for State assistance than could ever be put forward by its competitors. He emphasized the necessity for stern opposition to the proposal to subsidize electricity at the cost of the gas industry.

A COMPANIES' SECTION OF THE "B.C.G.A."

As Chairman of a Company undertaking, Mr. Barber said he would like the Association to consider the desirability of forming a Companies' Section. He thought this might be of great service. They had realized the benefits of close co-operation in matters generally affecting the industry, but there were many domestic matters concerning a company undertaking which did not affect municipal undertakings, on which conferences and common action by companies might be of great benefit. He would instance such matters as the raising of capital, standard dividends, rates of dividends, basic and maximum prices, assessments to local rates and taxes, precedents of Parliament in dealing with company legislation, and combined action to meet persistent demands of road boards and railway companies, for the insertion of special clauses in a Company's Act, and other matters in which they were concerned and in which the municipal undertakings were not.

LIGHT AND HEALTH.

Dr. R. Veitch Clark, M.A., M.B., Medical Officer of Health for Manchester, gave an extempore address, with the aid of charts, entitled "Light and Health," in the course of which he dwelt on the importance of sunlight to human health and prosperity, and the enormous influence of the smoke-pall, caused by burning raw coal, in creating disease and depriving people of the benefits of sunlight. Everybody who lived and worked in an industrial community, he said, was well aware of the intense gloom that settled over towns even in the summer months. He had noticed it himself in Manchester only the previous day. He was not at that conference as one having any interest in the gas industry, but as one who hated the coal chimney. To think that a black fog could settle on the town in May, in this age of science and civilization, was an absolute disgrace. Anything that would help to sweep away the intensely depressing conditions of industrial life was a thing to be encouraged by everybody in authority; and this was why he supported the gas industry. The speaker described the nature of the filth and products breathed by people in a smoky atmosphere, and the effect on the lungs and on health. These things of themselves undoubtedly hastened death, but even more important, probably was the fact that the smoke shut out the beneficent sunlight and the invaluable ultra-violet rays, the nature of which he proceeded to describe. Ages ago people worshipped the sun because they realized that it was the source of all life and health; and yet in these days of civilization we shut out the sun by our own folly. We went away from town to holiday places to get the sun which we could get at home if we did not burn raw coal. The speaker described sunshine treatment for tuberculosis and other disease in Switzerland, and at a sunshine sanatorium under his own charge in North Wales, and spoke of remarkable cures without the aid of medicine or surgery. He said he would urge the application of any kind of power or authority that would compel the minimization of smoke.

GAS AS A PUBLIC SERVICE.

By FRANK H. ROBINSON, Assoc.M.Inst.C.E.

Few people realize the extent to which gas enters into public life; most think only of its domestic uses for lighting, heating, and cooking, without realizing the extent to which gas and its bye-products enter into the manufacturing and business life of the country.

To dwell for a moment on the domestic aspect of the use of gas, it is interesting to know that to-day there are over 8½ million consumers in Great Britain and Ireland, and that more than half this number are supplied with gas through the prepayment meter. It is no exaggeration, therefore, to say that gas is giving service in some form or other, for cooking, heating, lighting, or hot water supply, in practically every home in the land. Another interesting point in this connection is that the greatest demand for gas throughout the country at any given time occurs between the hours of 11 and 1 o'clock on Sundays, when the millions of gas cookers are in use for preparing the Sunday dinner. This is a national festival that overshadows in importance the Derby or the Boat Race.

To turn to the use of gas in the industrial sphere, if I were to attempt to describe the variety of purposes for which gas is employed in the manufacture of practically every known want of man, I would need to write a treatise, as there are over 3000 known processes in which gas plays an important part. I propose, therefore, to deal only with the use of gas in a resort like Harrogate; but, before proceeding to this particular subject, there are one or two points with which I would like to deal briefly.

The scientific carbonization of coal on the gas-works is a

potent factor in the all-important question of the conservation of that national asset coal; and it is well that the public should realize that, in extracting the heat units from the coal and supplying them for the needs of the community in the form of gaseous fuel, all the valuable bye-products are recovered. They are wasted when coal is burned in its raw state.

Another point on which I should like to comment is the enormous magnitude of the gas industry. We see in some of the newspapers to-day fantastic claims and ideas with regard to the use of electricity being the "panacea for all ills." While we all recognize that electricity has its proper place in service to the community, we must view it in proper proportion, and not be misled by statements which are, to say the least, fantastic. The Governor of the largest gas company in the world, in a recent speech, made the statement that the total heat units supplied by that one Company alone to its consumers was greater than the energy supplied to this country by the whole electrical industry. When I tell you that that Gas Company's output represents between 12 and 13 p.ct. of the total output of the whole industry, you get some conception of the relative magnitude of the service which the gas and electrical industries are providing for the community generally. After well over a century of service to the public, the gas industry continues to progress, and is a much more lively and virile body than some of its competitors would have the public believe.

The hygienic aspect of the use of gas in the home is a subject of considerable interest and importance, and it is gratifying alike to the industry and, I suggest, to the general public that the claims made by the gas supply industry as to the many advantages of gas from a health point of view are supported and confirmed by the great bulk of the medical profession, who are big users of gas in their own homes and consulting rooms. It is a fact that, of the London residential districts, the Harley Street area, which houses the leading men in the medical profession, shows the largest consumption per acre. Similarly gas is very extensively used in a large number of hospitals, both in London and throughout the country.

Besides being noted as a spa, Harrogate has a wide reputation for a very pure atmosphere. The use of gas and coke has contributed very largely to the beautiful clear air of the town. Imagine for a moment what conditions would be like in Harrogate if the 11,000 gas consumers were to use only coal for their cooking and heating—every kitchen chimney belching forth smoke; every hotel, hydro, and boarding establishment doing the same; a procession of coal carts to these places; and the resultant procession of dust carts removing ashes every morning; black dust mixed with brown dust, soot and grime in the bedrooms, and over the town a pall of smoke. This would not attract people to Harrogate to take the "cure" or spend their holidays. It would also mean more traffic in the streets, more labour in handling refuse, and consequently higher rates, and larger staffs in the hotels and hydros. Altogether, apart from the effect upon the health of the inhabitants, the picture would not be good to look upon. I do not propose to touch on this side of the question, as it has been already dealt with in a most capable manner by Dr. Veitch Clark, the Medical Officer of my native city.

In Harrogate, there is scarcely a boarding-establishment, apartment-house, hotel, or hydro without gas for cooking purposes. This is a sufficient testimonial to the convenience, economy, and cleanliness of gas for this work. The gas cooker is always ready for use; there is no waiting for the fire to burn up; and no necessity to get up an hour earlier to provide breakfast for the visitor who wishes to catch an early train. Breakfast can be prepared at a few minutes' notice, and the cooker turned out when the meal is ready, and left out of use till it is time to prepare for lunch; and thus the kitchen does not become insufferably hot, as it would if a coal fire were used.

In the bathroom a gas geyser is most useful to the visitor in an apartment-house who desires to have a hot bath at any time, without having to give special notice to the landlady to have the water hot. In the larger boarding establishments the gas circulator or the coke-fired boiler is more suitable, providing, as it does, hot water at all times, and also a means of consuming, along with the coke, the combustible refuse which accumulates in such establishments.

There are many of the larger hotels and hydros in Harrogate with very complete equipments for heating and cooking by gas and coke, notably the Cairn Hydro, the George Hotel, the Harrogate Hydro, the Queen Hotel, and the Adelphi Hotel; but there are still proprietors who have not yet realized to the full the great advantages of gas for all purposes in the kitchen, still-room, or elsewhere.

The Cairn Hydro kitchen is fitted with a large gas roasting oven, three double gas ovens with hotplates, two large hotplates and boiling tables, one with ten and the other with six gas rings, a stand for two stockpots, also two vegetable steamers and a hot closet heated by steam derived from a boiler fired by coke. The still-room contains a gas-heated toaster, a hotplate, and two steam kettles. In the kitchen no solid fuel is used. This establishment caters for 300 guests. The general heating is done by radiators supplied from a coke-fired boiler. The gas undertaking therefore supplies all the heat for the feeding and warming of the 300 guests and the staff in this large establishment. It is therefore very much a public servant, and is always on duty.

The George Hotel, close to the Cairn Hydro, also has a very complete gas equipment. In the kitchen there are: A gas cooker with four ovens and hotplate; a gas cooking range, fitted into a recess formerly occupied by coal-fired ovens, comprising two pastry ovens and a large hotplate, mostly constructed by the Gas Company; a gas roasting oven; stock-pot stand made by the Company; a steam-heated bain-marie; a steam vegetable oven; a gas griller mounted on a gas oven. In the serving room there is a long steam-heated hot-closet and a Jackson boiler; while the still-room contains two gas-heated coffee urns, a six-burner boiling-table, and a large toaster. This hotel caters for about 130 to 150 guests. All the steam required is raised in a coke-fired boiler.

The Adelphi Hotel is another which has all-gas equipment. In the kitchen there are: A hotplate 6 ft. long, a toaster, a large double roasting oven, a single oven, and a stockpot stand. In the still-room and serving room there are: A Jackson boiler, two toasters, a hotplate, a 5-gallon boiler, and a large hot closet. All the above are gas-heated appliances. General heating is done by radiators from a coke-fired boiler.

The examples given above are only three among many, and are detailed to show how much the public are served by gas and coke in a health resort.

There is one advantage attached to the use of gas appliances in large kitchens which is sometimes overlooked—viz., the ease with which the place can be kept clean, particularly about the floor. Smoke and soot are absent, and the appliances can be placed upon stands, leaving a clear space beneath to permit of the floor being swept and washed. Also a re-arrangement of the appliances is easily obtained, if desired, without structural alterations, and additional appliances can be installed with nothing more than a pipe and perhaps a short length of flue. This cannot be done with coal-fired apparatus.

To give some idea of the extent to which gas can be applied

FIG. 1.—KITCHEN OF THE CAIRN HYDRO, HARROGATE.

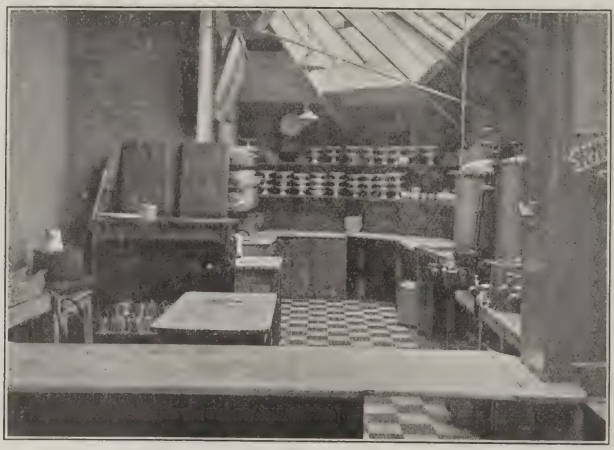


FIG. 2.—STILL-ROOM OF THE CAIRN HYDRO.

in catering for the needs of the public in seaside and health resorts, I have prepared the following list, which should not, however, be taken as exhaustive.

Cooking.—Gas roasting ovens, pastry ovens, hotplates, stockpot stands, vegetable steamers, grillers, pudding boilers, &c., bain-maries, fish fryers, &c.

Still-Room.—Gas boilers for hot water, coffee boilers, toasters, hot closet for keeping plates and dishes warm, &c.

Bathrooms.—Gas geysers, heated towel rails, circulators.

Corridors.—Gas radiators, or hot water radiators supplied from coke-fired boilers.

Bedrooms.—Gas fires with shilling prepayment meters.

Lounges, Drawing Rooms, &c.—Gas fires and radiators.

Garages.—Safety gas radiators.

For many years the bedroom fire has been a source of trouble and expense to both visitor and management. In the early spring or late autumn a fire in the bedroom is a boon. People coming to Harrogate for treatment at such times, and more so in the winter, find a bedroom fire not only a necessity but a comfort. They are often deterred from having one by the charges made for a coal fire and the nuisance of members of the staff having to attend to it, while the management of the hotel dislike having to light a fire with the consequent handling of coal, ashes, &c., and the extra labour involved. The result is that people avoid going away at these times, and the hotels lose business.

The gas fire with a prepayment meter attached overcomes these difficulties and provides the visitor with comforts such as he or she is accustomed to at home. The fire can be lighted when desired, to take away the chill of the room during (say) dressing for dinner or retiring for the night. In case the visitor is suffering from any complaint requiring warmth, the gas fire is available continuously or intermittently. To make a visitor comfortable is to attract custom, for each satisfied visitor is a missionary.

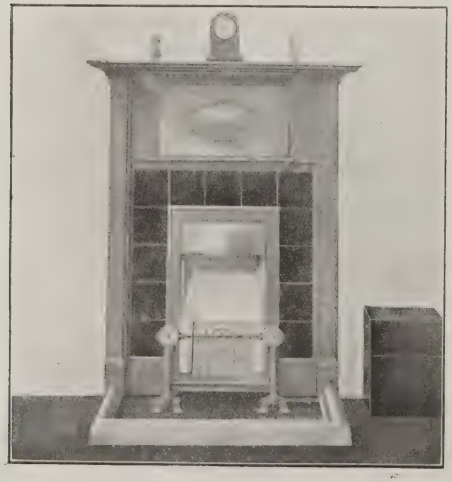

Fig. 3.—Typical Hotel Bedroom Gas Fire.

It must not be thought that the visitor gets all the benefit. It is a paying proposition to the management, apart from the attraction which it proves. The whole gas supply to the hotel or hydro passes through the main meter, and the establishment is charged at the usual price, subject to special discounts for large consumptions. The slot meters attached to the fires are set to give such a quantity of gas for a shilling as will cover the rent of the meter, if any, and leave a margin to pay interest on the capital cost of fire and piping. Take the following case with the costs given :

Gas (460 B.Th.U.) at 9d. a therm (gross) less 10 p.ct. discount			8·1d. net.
Gas fire, with piping, average cost	£5	15	0
Hire of extra meter, 1s. a quarter = 4s. a year	0	4	0
Slot meter set at 216 c.ft. a shilling = 4s. 7½d. per 1000 c.ft. net, or 1s. a therm net.			

If we assume the fire to be used only two hours a day for 150 days in the year, some 10,500 c.ft., or 48 therms, would be used in the average bedroom, costing the visitors about 2d. an hour. In other words, the visitor would have the benefit of a fire for dressing, morning and night, for a whole week for two shillings, which is much less than the cost of coal fires for that period.

The cash put into the meter in the year would be £2 8s. This amount could be collected by the gas inspectors, and credited to the gas account of the hotel, or by the hotel management, as may be arranged. The costs would then work out as follows :

	£	s.	d.
48 therms at 8·1d. net	1	12	5
One year's rent of slot meter	0	4	0
	£1	16	5
Received from slot meter	2	8	0
Annual profit to hotel proprietor, per fire = 10 p.ct. on capital expenditure.	0	11	7

These figures are based on the actual costs and prices in the case of a private hotel in Harrogate with seven such gas fires, and show the benefit to be obtained even where there is no winter season. The proposal is even more attractive to both visitor and hotel proprietor in places such as Bournemouth, Torquay, Hastings, Eastbourne, &c., where there is a winter season. The service given by gas to the public in such resorts is not limited to the hotels and hydros, &c. The bread and confectionery supplied to the tables is baked in gas and coke heated ovens at the local bakehouses. When the visitors take a stroll in the town or the gardens, and have afternoon tea, gas is again their servant in providing tea, toast, &c. Again, when they go to the theatre or concert hall, and the night is chilly, heat from the radiators is available to make them comfortable; the source of that heat being coke, a product of the gas-works.

In the boarding schools and colleges, of which there are many in Harrogate, the equipment in the kitchens is very similar to that of the hotels. The Ladies' College, Queen Ethelburga's School, Pannal Ash College, Ashville College, and New College have a considerable amount of gas apparatus in the kitchens. In all such places the use of gas makes for cleanliness, economy, convenience, and reduction of labour, combined with absolute reliability, which cannot be obtained by the use of coal. The regulation of the heats for the various cooking and heating operations is more easily obtained; and consequently there is less waste. If no such benefit had been

obtained, the use of gas for these purposes would not have extended at the rate it has done.

Before the commencement of the holiday season, the appliances at most places are examined, repaired, and adjusted by us. Likewise, the schools and colleges have their apparatus overhauled before the commencement of each term. In addition, the Company's gasfitters are available at any time for keeping all appliances working at full efficiency. Too often it occurs that results are spoiled through proprietors not taking the trouble to acquaint the Gas Company of their difficulty, though the Company have expert advice and assistance at free disposal. No charge is made either for advice or for the regulating of apparatus, but only for repairs, cleaning, and overhauling. If such proprietors would realize that it is economical to have regular inspection, and keep their appliances in good repair, they would be doing themselves, their customers the visitors, and the Gas Company a service.

Many people talk glibly about gas being done for; but they do not appreciate how much they are dependent on the gas undertaking, especially when they go away from home. The foregoing will, I hope, serve to make the people realize how much gas is a public service. There is plenty of room for further use of this service. Some who cater for the public needs have found its value, but there are many others who have not yet completed their education.

Discussion.

Dr. JAMES MAIR said that Dr. Veitch Clark had put the subject in so lucid a manner that little was left to add. He certainly agreed entirely with what had been said. Recently he had read a book entitled "The Smokeless City," by Mr. Simon, formerly Lord Mayor of Manchester, who took Manchester as the type of smoky city and Harrogate as the smokeless town. In Harrogate, it was true, the nuisance from industrial smoke was practically non-existent, but there was the smoke from houses. The domestic smoke in Harrogate did not, perhaps, shut out the ordinary sunlight, as did industrial smoke, but it did cut off the ultra-violet rays which were so valuable. He would be interested to have the views of Dr. Clark or any other authority as to the best means that could be taken to prevent this pollution of the atmosphere by smoke. In many industrial towns they had legislative powers which to some extent dealt with industrial smoke, which, he believed, was being reduced; but there was no power to prevent house smoke. They must make the public realize the evil of this smoke.

Mr. ELLIS said the question of coal conservation had recently been raised in Parliament by Lady Astor, who suggested that the legislature should do something further. By all means do everything possible by legislation, said Mr. Ellis; but he had far greater faith in publicity of such important and vital scientific facts as Dr. Veitch Clark had given to the meeting. This was what the "B.C.G.A." were out to do.

Councillor DAY (Halifax) said he was entirely in agreement with the views expressed by Dr. Veitch Clark. In Halifax they were trying to do their part to recover the benefits of sunshine.

Mr. MALLINSON, Proprietor of a Harrogate hotel, said his was the hotel to which Mr. Robinson had referred in mentioning an installation of gas fires in bedrooms. He had four installed, and was so satisfied that he got another five, and now he had received bookings from visitors specifying the bedrooms in which were gas fires. He found also that the fires saved him at least one servant.

The MAYOR OF HALIFAX said he had been Chairman of the Gas Committee there for many years, and in Corporation houses now they were making no provision for the burning of raw coal in bedrooms. If public representatives would take up the great question of the smoke evil, and apply their convictions to the prevention of coal fires in bedrooms, they would achieve a great deal.

Dr. CLARK and Mr. ROBINSON briefly replied.

On the motion of Mr. MASON, thanks were tendered the Chairman and all who had contributed to the success of the meeting.

New Holder at Marsden.—Messrs. Firth, Blakeley, & Co., of Church Fenton, have just completed for the Marsden (near Huddersfield) Urban District Council a new gasholder of 200,000 c.ft. capacity. The holder stands on Council land adjoining the gasworks.

Price of Gas at Arbroath.—The Arbroath Town Council have been assured by Mr. John Souttar (the Convener of the Gas Committee) that there is no prospect of an increase in the price of gas. Contracts have been entered into for 11,500 tons of coal, at a price of about 5s. 7½d. per ton less than last year.

Smethwick Gas Undertaking.—In his annual report for the year ended March 31, Mr. Ernest Hardiker, Engineer and Manager, records an increase in the consumption of gas of over 94 million c.ft., equal to 12·83 p.ct. The use of gas for industrial purposes, he mentions, has risen from 84 million c.ft. in 1910, to 366 millions during the past year. This is equal to 45·91 p.ct. of the total quantity sold. Mr. Sidney Taylor, Borough Treasurer, states that the gross profit for the year was £29,538, and the net profit £10,196.

Meters, Ltd.—The report to be submitted at the meeting in Manchester next Wednesday (June 10) states that the accounts for the year ended March 31, with the balance brought forward, show a total sum of £26,876; and after deducting interim dividends, there is a balance available for appropriation of £20,204. The Directors recommend the payment of final dividends of 2½ p.ct. (actual) upon the preference shares, and of 6 p.ct. (actual) upon the ordinary shares—making the total dividends for the year 5½ p.ct. on the preference shares and 8½ p.ct. on the ordinary shares, both less income-tax. This will leave to be carried forward a balance of £7812, subject to corporation profits tax.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Subsidizing Electricity.

SIR,—There is more than one way of killing a cat!

I am to an extent in sympathy with Mr. Milne Watson's attitude in regard to the proposed subsidizing of the electric undertakings by the Government. At the same time, I realize that there is a far better way of meeting this matter than by crying over it. The gas industry is blessed with an Act of Parliament that allows all qualities of gas to be distributed; and it would be a fairly good answer to the gas industry's cry if the Government said: "We are subsidizing electricity to make competition with you keener, and to cause you to look to the methods you adopt."

I have maintained for some years that coke production is fatal to the gas industry's interests. On the other hand, the leaders of the gas industry claim that coke-making is essentially an integral part of the process of town gas production. I join issue with these leaders, and ask them to declare frankly what the costs of coke production are.

Let the proposition be examined in the light of the following questions:

(1) Why does the gas industry favour the production of a rich gas and a make of 70 therms per ton, with coke?
(2) Why does the industry not produce (say) 170 therms and no coke?

If any gas undertaking's accounts be examined by an unprejudiced accountant, it will be found that coke production costs at least as much as is obtained for it outside the cost of the coal from which it is obtained. For example: 13 cwt. of coke are produced per ton of coal. It requires no effort to realize the 13/20ths of the manufacturing plant is provided and used for the manufacture of coke.

	Per Ton of Coal Carbonized. s. d.	£ s. d.
Cost of coal . . .		1 13 2
Repairs and maintenance of works . .	15 4	
Wages, carbonizing .	3 2	
Capital charges, including profit . .	14 8	
		1 13 2
		£3 6 4

	s. d.	£ s. d.
Cost of coal due to coke production, 13-20ths of £1 13s. 2d. . . .		1 1 6
Proportion of repairs and maintenance of works due to coke production, 13-20ths of 15s. 4d. . . .	10 0	
Do. wages, carbonizing, 13-20ths of 3s. 2d.	2 1	
Do. capital charges and profit, 13-20ths of 14s. 8d. . . .	9 6	
		1 1 7
		£2 3 1

The sale of coke per ton of coal realizes 16s. 4d.

These figures, taken from actual accounts, show that the cost of coke per ton of coal carbonized is £2 3s. 1d. If £1 1s. 6d. be deducted, the amount left is £1 1s. 7d., and yet the coke is sold for 16s. 4d.—a dead loss, outside the cost of the coal, of 5s. 3d.

The total loss on coke production is £2 3s. 1d., *less* 16s. 4d.—that is, £1 6s. 9d. per ton of coal carbonized, and this without reckoning the office or other standing charges for the production and salesmanship of coke.

Do not let us imagine, therefore, that coke production is a profitable part of our business. Is it absolutely essential to produce coke? If so, little or nothing can be said. But is it?

GEORGE HELPS.

Nuneaton, May 25, 1925.

Heating Bath Water by Electricity.

SIR,—On more than one occasion we have crossed swords on matters relating to electricity supply, and I think our discussions have been conducted without acrimony on either side. Your comments in "Electricity Supply Memoranda" dated May 27 on Poplar Baths calls for a reply from me regarding the cost of supply of electricity for heating bathing water.

I am not at all surprised at your comments, because, prior to giving consideration to this form of heat supply, I was of a similar opinion to yourself, as was possibly every engineer in the country. You know, however, the old adage "fools rush in where angels fear to tread"; hence, I suppose, your reference to the "real live" Electrical Engineer of Poplar.

You assert that the electric heating of water is an "impudent stunt," and that it is not cheaper than gas. The circumstances of the case are as follows:

When these baths were instituted, the Poplar Baths Committee applied to the Gas Company for a supply on trade terms—viz., 35 p.ct. off ordinary standard price, which the Company refused to grant. I found that it would pay my Committee to supply at equivalent prices, and it was decided to instal a small heating outfit at our Wick Lane establishment. Immediately the Gas Company became aware of our intention, they agreed to the factory terms, which rendered the proposition before me totally different. However, I was convinced that this problem had opened-up enormous possibilities for the outlet of electrical energy, and I recommended my Committee to agree to supply at average fuel cost only. I gather from your remarks that this is what you object to. The present cost of electricity is now less per bath than gas at current rates, and the saving effected in maintenance is all to the good.

You are perfectly aware from the information given in the "Memo-

randa" relating to off-peak periods that this sort of supply is a bye-product, and must be regarded as such. In your own industry bye-products are worth exactly what they will fetch in the market. You cannot shut your eyes to this fact, as all the important gas companies have recently raised their charges by 10 p.ct. on account of the drop in value of their bye-products.

Your quarrel with me seems to be that I ought to overlook the cost of supply with charges that are not incurred in giving this particular supply, which does not incur "distribution, capital, and other charges."

You are entirely wrong in assuming that the actual cost of production is greater during off-peak periods than at other times. Stand-by costs are higher; but these, again, do not apply to this class of load, as they would have to be incurred whether we were supplying baths or not.

The actual figures are 2¾ lb. coal per unit without stand-by; cost of coal 0·1d. per lb. Therefore cost per unit is 0·25d., *plus* conversion and distribution 20 p.ct., actual cost 0·3d.; but we are charging at the "average" cost of fuel, which is 50 p.ct. greater.

Now in your case the supply is not a bye-product, and probably with 35 p.ct. off your selling price there is not much margin for profit. I do not suppose for one moment that the "Gas Company are such asses as to supply gaseous energy at bare net fuel cost;" but there is no comparison between gaseous energy and electrical energy, and the inference which you evidently intend to convey that my Committee is comprised of "such asses" loses its point.

I think you will agree with me that the only thing that matters in connection with the supply of any commodity is the price at which such commodity can be supplied.

The irony of the matter is that I should never have been called upon to consider the question if the Gas Company had been reasonable at the outset, and had allowed factory terms. When developments have reached the point of justification, it is the gas industry that "squeals."

Now let me tell you something which may interest you more than the "queer things done in Poplar."

You are aware that a 30 p.ct. load factor is good for an industrial electricity supply undertaking. You will realize that an average of 70 p.ct. of plant and mains is practically idle all the year round. When it is generally recognized that certain supplies can be given at an average fuel cost with profit to any undertaking, I venture to predict that the gas industry will find the electricity industry a healthy competitor in water heating.

Another "queer thing" that Poplar is doing is to erect a power station that will utilize waste products of collieries. In many cases products that are now waste have a calorific value of 10,000 B.Th.U. and over. Energy will be generated from about 1⅛ lb. of this waste, and the price will be certainly not less than 33⅓ p.ct. of present coal prices; therefore the cost per unit, allowing for conversion and distribution, will not exceed 0·15d.

The "real live" Electrical Engineer of Poplar cannot afford to rule out fuel costs altogether, but these costs will be so small, and the field of supply so vast, that the Gas Company will feel sorry that they brought about competition of this sort.

In this instance, there will be no "scandalous misuse of coal," as no "coal" is required; therefore the outcry of "extravagant heat expenditure" will prove of little avail to the gas industry.

I am sending your paper to Mr. Jefferson Hope, who may think it worth while to reply to the second and third paragraphs of your "Memoranda;" but I would just like to mention that the cost quoted by you, 0·517d. in September, 1923, has now fallen to 0·338d. in March last, with every prospect of a steady decrease until the new station is in working operation.

I. HORACE BOWDEN,
General Manager and Chief Engineer.

Electricity Works, Glaucus Street, Bromley-by-Bow, E. 3,
May 29, 1925.

[This letter arrived during the Whitsun holiday absence of the writer of "Electricity Supply Memoranda;" but we will not delay its publication.—ED. "G.J."]

REGISTER OF PATENTS.

Non-Atmospheric Gas Burners.—No. 211,473.

BAKHUIZEN, W., of Potsdam.

No. 3596; Feb. 12, 1924. Convention date: Feb. 13, 1923.

The patentee claims: A non-atmospheric burner of the kind in which the burner head is provided with converging nozzles or jets arranged in pairs or in groups, distinctive by the axes of the nozzles of each pair or group being disposed at an inclination to one another constituting an extremely acute angle—for example, 10°—so that the flames unite or touch each other in a manner lengthening or pulling them out distinctive from broadening. The pairs or groups of nozzles are arranged in circles one above another in the wall of the burner head, or concentrically in the top of the burner head, which has vertical, horizontal, or oblique depressions or grooves cut in it.

Wash Boilers.—No. 232,694.

SUGG, W., & CO., LTD., and SUGG, P. H., both of Chapter Street, S.W. 1.

No. 2071; Jan. 25, 1924.

This invention seeks to prevent condensed water containing iron oxide finding its way back into a wash boiler, and splashings running down to the gas burner.

The outer casing is provided with an out-turned flange having an annular groove engaged by a corresponding bead on the out-turned flange of the inner pan. A ring of asbestos or other suitable material is inserted in the groove.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

Kilmarnock Gas and Water Provisional Order Bill: Brought from the Commons, read the first time, and deemed to have been read the second time and reported from the Committee.

Stockton-on-Tees Corporation Bill: Read the second time, and committed.

Gas Light and Coke Company Bill: Reported, with amendments.

Blackpool Improvement Bill and Oldham Corporation Bill: Read the third time, passed, and sent to the Commons.

South Metropolitan Gas Bill: Brought from the Commons, read the first time, and referred to the Examiners.

Mansfield Corporation Bill: Reported from the Select Committee, with amendments.

Forfar Gas Order Confirmation Bill: The Royal Assent reported.

HOUSE OF COMMONS.

Progress of Bills.

South Metropolitan Gas Bill: Read the third time, and passed.

Gas Regulation Act.

Copies were presented of the drafts of Special Orders proposed to be made by the Board of Trade under section 10 of the Act, on the applications of the Preston Gas Company, the Harrogate Gas Company, and the Hastings and St. Leonards Gas Company.

On the motion of Sir Burton Chadwick, the draft Special Orders relating to the Trowbridge undertaking of the British Gas Light Company, and the Haverfordwest Corporation were approved.

GAS LIGHT AND COKE COMPANY'S BILL.

The Unopposed Committee of the House of Lords (presided over by the Lord Chairman, the Earl of Donoughmore), on Tuesday, May 26, ordered this Bill to be reported for the third reading. There have been no amendments, other than matters of drafting, since the Bill left the House of Commons. (The provisions of the Bill, and the proceedings in the House of Commons, were dealt with in the "JOURNAL" for Jan. 7, p. 30, and April 1, pp. 29 and 61.)

MANSFIELD CORPORATION BILL.

This general provisions Bill has been before a Committee of the House of Lords for some days, and has now been ordered to be reported for third reading. Originally, it contained a clause relating to the gas undertaking of the Corporation, relieving the Corporation of the obligation to supply gas for other than lighting and domestic purposes from any main the capacity of which is insufficient. This clause has been the subject of objection by the railway companies for a long period; and prolonged negotiations have been taking place between the National Gas Council and the railway companies, with a view to arriving at an agreement as to the form which the clause should take. Agreement has at last been reached, and, in consequence, the clause in its original form in the Mansfield Bill has been deleted, and the agreed clause substituted.

The original clause in the Mansfield Bill was as follows:

> "Notwithstanding anything in any enactment to the contrary, the Corporation shall not be obliged to give from any main a supply of gas for any purpose other than lighting or domestic use in any case where the capacity of such main is insufficient for such purpose, or if, and so long as, any such supply would, in the opinion of the Corporation, interfere with the sufficiency of the gas required to be supplied by means of such main for lighting or domestic purposes."

Prior to the agreement which has now been reached, there have been attempts on the part of the railway companies to have the matter fought out in Parliament; and for this purpose they have opposed various Bills containing the clause in the above form. In most cases, however, the promoters have withdrawn the clause. The railway companies have also lodged objections to the clause when it has been included in Special Orders which the Board of Trade have been asked to make in favour of various gas undertakings; and it had more or less become the practice for the promoters of these Orders to delete the offending clause, pending the agreement which it was hoped would result from the negotiations taking place between the railway companies and the National Gas Council, and to insert the agreed clause in its place. A number of Orders were granted, however, before agreement was reached, and these did not contain any clause dealing with the matter.

Subsequently, an Order was promoted by the Pinner Gas Company in connection with which this matter was raised; and when inquiry into the granting of the Order was held at the Board of Trade, the Company intimated their resolve to have the matter referred to a Parliamentary Committee for decision. [Proceedings at the Board of Trade in connection with the Pinner Order were reported in the "JOURNAL" for June 18, 1924, p. 582.] The matter was subsequently referred to a Committee of the House of Commons (see "JOURNAL" for Aug. 6, 1924, p. 524), and the result of the discussion there was that the matter was postponed until the Autumn Session of Parliament, with a view to the parties arriving at some form of words to meet the difficulty. The clause in the Pinner Order was practically the same as in the present Mansfield Bill. A previous case in which this matter was referred to a Parliamentary Committee was that of the Special Order of the Marple Urban District

Council (see "JOURNAL" for April 9, 1924, p. 123), but in that case the clause was withdrawn because the Urban District Council were not in a financial position to fight the railway companies in Parliament.

THE AGREED CLAUSE.

The agreed clause which has been inserted in the Mansfield Bill, and which has also been inserted in the Board of Trade Order to the Pinner Gas Company is as follows:

"Unless at the date of the demand for any such new or increased supply of gas as is hereinafter referred to the capacity of the distribution works of the Corporation is, in the opinion of an arbitrator, appointed as hereinafter provided, insufficient to meet (with a reasonable margin) the requirements (as existing immediately before that date) of the consumers in the portion of the area of supply of the Corporation for which such works have been provided (so far as such requirements could reasonably have been foreseen), the Corporation, notwithstanding anything contained in any other enactment, shall not be obliged to give for any purpose other than lighting or domestic use—

(*a*) A new supply of gas for the premises of any person demanding such supply at any time after the passing of this Act; or

(*b*) an increased supply of gas (other than an increased supply necessitated by any reduction of the declared calorific value of the gas);

where the giving of such new or increased supply would render necessary the laying of a new main or the making (as an alternative to the laying of a new main) of any enlargement or alteration of, or addition to, the distribution works of the Corporation. Provided that the foregoing provisions of this section shall not apply in any case in which the person demanding the new or increased supply (in this section referred to as "the applicant") shall enter into a written contract with the Corporation—

(i) To receive and pay for a supply of gas of such minimum quantity and for such minimum period as the Corporation may reasonably require; or

(ii) to make such payment or payments to the Corporation (in addition to any payments to be made from time to time for gas supplied to the applicant) as the Corporation may reasonably require;

(according as the Corporation may in their discretion determine) in consideration of, or by way of contribution towards, the expenses to be incurred by the Corporation in laying such new main or making such enlargement, alteration, or addition as aforesaid, and shall give such security for the payment of all moneys which may become due under the contract as the Corporation may reasonably demand. Provided also that, if any question shall arise under the provisions of this section between the Corporation and the applicant as to the sufficiency of the distribution works of the Corporation, or as to whether such new or increased supply would necessitate the laying of a new main or the making of any such enlargement, alteration, or addition as aforesaid, or as to the reasonableness of the minimum quantity or period or of the payments (in addition to payments for gas supplied) required by the Corporation, or as to the nature or amount of the security demanded by the Corporation, such question shall be referred to and determined by an arbitrator to be appointed (failing agreement between the Corporation and the applicant) by the Board of Trade on the application of either party after notice in writing to the other of them; and the decision of such arbitrator shall be final and binding. Provided also that, in determining any such question as aforesaid, the arbitrator shall have regard to the following, among other, considerations (that is to say):

(A) The total annual quantity of gas required by the applicant, the maximum quantity required per hour, and the hours of the day during which the Corporation may be called upon to supply gas to the applicant.

(B) The capital expenditure which the Corporation would have to incur in the laying of a new main or the making of any enlargement or alteration of, or addition to, their distribution works as aforesaid in connection with the giving of such new or increased supply.

(C) How far such capital expenditure may become unproductive to the Corporation in the event of the cesser of the new or increased supply.

Subject as aforesaid, the provisions of the Arbitration Act, 1889, shall apply to any arbitration under this section.

BARROW-IN-FURNESS CORPORATION BILL.

This Bill (see "JOURNAL" for Jan. 21, p. 142, and April 15, p. 187), which contains a number of clauses of a general character relating to the Corporation's gas undertaking, was ordered by the Unopposed Committee of the House of Lords (presided over by the Lord Chairman, the Earl of Donoughmore), on Tuesday, May 26, to be reported for third reading. There are no substantial changes in the gas clauses since the Bill left the House of Commons.

NEW SHOREHAM HARBOUR BILL

The Unopposed Committee of the House of Commons, presided over by Mr. JAMES F. HOPE (Chairman of Ways and Means), on Tuesday, May 19, ordered this Bill to be reported for third reading. Its purpose is to enable the Harbour Trustees to continue for a further period to increase their statutory maximum rates and charges by 100 p.ct., and to purchase land for the development of the harbour. There was originally a petition against the Bill by the Brighton and Hove General Gas Company, whose coal is discharged in the harbour, but the petition was withdrawn as the result of agreement being reached. The Gas Company objected to the Trustees having power to acquire part of their lands, and to the extension of the power to charge increased rates permanently. The increase was originally given under an Order which was strictly temporary in character, and which contained a provision, inserted at the instance of the Gas Company, requiring the Trustees to spend the additional revenue obtained as the result of the increase of rates for the benefit of the harbour undertaking; and it was pointed out by the Gas Company that, under the powers sought in the present Bill, the Trustees would be able to apply the revenue to purposes of a different character.

Mr. C. F. BAKER (Messrs. Bircham & Co., Parliamentary Agents) said that, whereas the Bill originally provided for a permanent increase of the statutory maximum rates by 100 p.ct., it was now provided that the increase should operate for three years from December, 1925.

There was a clause in the Bill providing that, if the Gas Company and other bodies mentioned, and the Harbour Trustees, should agree in writing a scheme for the reorganization, reduction, and consolidation of the existing capital of the Trustees, for the raising of additional capital by the Trustees, and the reconstitution of the Trust, and other incidental matters, the Trustees are to promote a Bill in the next available session of Parliament to give effect to this scheme, and to include such other matters as may be agreed between the parties mentioned. If no Act to give effect to such a scheme has been obtained by the Trustees before Oct. 1, 1927, the Gas Company and the other bodies may promote a Bill for the purpose.

Replying to questions by the Committee, Mr. Baker said that this arose out of efforts which were being made to agree to a scheme between local authorities and the Gas Company on the one hand, and the security holders on the other, for the reorganization of the finances of the Trustees. What was being aimed at was the reduction and consolidation of capital.

Asked why the Gas Company were included, he said that they had a very large interest in the success of the Harbour, as the gas-works were dependent upon it.

LEGAL INTELLIGENCE.

GAS PIPES AND ROAD FILLING.

Liverpool Corporation to Pay Damages.

At the Manchester Assizes last week Mr. JUSTICE FINLAY gave judgment in an action which had been heard by him on four days at the last Liverpool Assizes. The substance of the case was a claim by the Huyton and Roby Gas Company, Ltd., for damages from the Corporation of Liverpool for injuries to their gas mains alleged to have been caused by the negligence of the defendants or their contractors.

The Judge held that a series of six fractures which occurred in gas pipes of the plaintiff Company in Archway Road and Roby Road during 1923, 1924, and 1925 was caused by the failure of the contractors, who laid down a water main for the defendant Corporation in 1923, so to restore the road as to afford adequate support to the gas pipes of the plaintiff Company. He was satisfied on the evidence that the fractures complained of, which resulted in several explosions of gas, were caused by subsidences which imposed an undue strain on the gas pipes. As to the suggestion for the defence that the plaintiff's pipes were laid too near the surface for safety, the Judge said it might be expedient in modern practice, having regard to the greatly increased strain imposed by the passage of heavy vehicular traffic at high speeds, to lay pipes deeper under the surface; but this did not relieve the defendants of their obligations. Before the water main was laid, there were no fractures in the gas pipes; and afterwards there were six fractures, of which no less than four occurred at points where the water main crossed the line of the gas pipes.

Mr. Justice Finlay dealt at some length with the defence that the plaintiffs were debarred from recovering under a provision of the Public Authorities Protection Act, 1893, which enacts that no action may lie unless begun within six months of the cessation of the acts complained of. He held that the time limit mentioned did not begin to run until the neglect ceased. In this case the defendants were under an obligation to fill-in the road properly after excavating. The road was not filled in with due care, and was still in the same condition; and the defendants were liable for damages caused by their failure and neglect.

He gave judgment for the plaintiff Company for the full amount claimed (£83), and, referring to the plaintiff's original claim to an indemnity, said that probably the judgment he had given would fulfil the same purpose; but as Counsel had agreed that the claim for an indemnity could not be pursued, he gave no judgment on that issue.

Public Lighting at Hereford.—In view of the criticism evoked in consequence of the discontinuance of public lighting, it has been decided to resume the public lighting until the date of next meeting of the Town Council, when the whole subject will be reconsidered.

Accrington and District Gas Board.—At a meeting on May 28, Mr. A. J. Harrison (General Manager) said they had just balanced their accounts for the municipal year. The increase in gas sales had been very satisfactory, totalling 37,352,000 c.ft. The unaccounted-for gas was less than the previous year by ten million c.ft. The expenditure on gas production and distribution was £92,143, or £3738 above last year. The income totalled £125,348, or £381 less than last year. Gas revenue had increased by £329. The total profits on gas were £33,204. Standing charges absorbed £32,878, so that there was an actual net surplus of £326. They proposed to place certain additions to plant to revenue account; and this would absorb that little surplus. It was not proposed to recommend any alteration in the prices during the present year.

MISCELLANEOUS NEWS.

BELFAST GAS UNDERTAKING.

The Engineer and Manager of the Belfast Gas-Works (Mr. J. D. Smith) has received the commendation of his Committee on the satisfactory nature of his annual report. His recommendation to extend the power rate to include gas used for cooking in hotels, restaurants, and large catering establishments was adopted.

The report shows the balance brought forward from the previous year to be £11,492. As the result of last year's working, this had been increased to £19,827. The gas made showed an increase of 120 million c.ft. The quantity of coal carbonized was greater by 10,187 tons. The production of water gas was reduced by about 12 p.ct.; and consequently there was a saving of 423,725 gallons of oil. The sale of coke continued to expand. The extra revenue from this source amounted to £13,650, and the sale had been very steady. The demand for gas increased year by year; and this was not to be wondered at, in view of the low price charged. The increase in sales through ordinary meters was 77 million c.ft., and through automatic meters 123 millions; while the increased revenue for the year amounted to £7010. Not only was the output larger, but they had a remarkable addition to the number of consumers, the increase for the year being 1925, bringing the total number of meters installed up to 90,549.

The chemical department had continued its prosperous career. There was a substantial increase in the output of tar and ammonia; and though the revenue was only increased by £911, this was entirely due to the drop in market prices. The production of tar and liquor constituted a record, and the chemical department had not experienced any difficulty in selling the entire production. The demand for all patterns of stoves had been enormous. The future for gas was, undoubtedly, largely in this direction. The total number of fires, heaters, &c., in use was 65,895—an increase of over 7900. The process of installing in the works the best and most modern plant had gone forward steadily, and all the appliances had been maintained in a thoroughly efficient manner. Contracts had recently been placed for new exhausters, condensers, and scrubber-washers. The balance in hand at the end of the last financial year was not sufficient to justify any reduction in the price of gas for lighting; but he thought the Committee could safely extend the power rate so as to include the gas used for cooking in hotels, restaurants, and large catering establishments. They were now feeling the benefit of the policy of modernizing the works. With gas at the cheap price at which it was supplied, there was practically no limit to the possibilities of the future.

The accounts for the year show that the gross profit on the manufacture and sale of gas and residuals was £110,671, and that out of the net profit a sum of £11,473 was paid in respect of dividends and sinking fund on the City Hall stock.

SAFEGUARDING OF INDUSTRIES ACT.

Gas Mantles.

(*Continued from p.* 611.)

Friday, May 22.

The Committee resumed their inquiry on Friday, May 22.

At the commencement of the proceedings, Mr. MACASKIE (Counsel for the opponents) made the request that he be provided with the British costs of production of gas mantles.

The CHAIRMAN asked whether these costs were material to the opponents.

COUNSEL submitted that they were.

The CHAIRMAN said that the applicants had given their costs to the Committee privately, and the opponents also could give their costs *in camera*.

Mr. *Soper* then re-entered the witness box, and was questioned further by the Chairman. As to the British exports of mantles, he said these totalled slightly over three million mantles a year. He believed that about 95 p.ct. of these went to the British Dominions, and practically none to foreign countries, because the British manufacturer could not get into those countries.

As to Mr. Soper's statement, in evidence, that he would prefer a flate rate to an *ad valorem* duty on imported gas mantles, the Chairman asked what it was considered this flat rate should be.

Mr. *Soper* said that under the Safeguarding of Industries Act, 1921, a 33⅓ p.ct. *ad valorem* duty was imposed. At present the average import price of German mantles was 21s. per gross, and the equivalent of that duty would be 7s. per gross. This, however, would not afford protection against importation from countries where conditions of labour were more unfair than in Germany. He considered there should be a flat rate duty of 10s. per gross.

Mr. *Bernard Hiller* (Traveller, of Messrs. Joseph T. Robin, Ltd.) gave evidence to the effect that it was hardly possible to sell British mantles against foreign mantles. He was selling the ordinary standard mantle, his minimum price being 26s. per gross, but it was very difficult to sell at that price. In reply to the Chairman, he said that German mantles were sold at a little over 20s. per gross, and those from other countries were sold at lower prices.

Witness, replying to Sir John Barran, said that in very few cases did the user of the mantle get any advantage in price as between the British and the foreign mantle. The mantles which he sold to the wholesaler he had seen retailed at 4d. or 4½d., which was equivalent to about 54s. per gross, and the retail price of the German mantle, which came into this country at about 20s. a gross, was 4½d. He had also seen both British and foreign mantles retailed at 6d.

Mr. *Benjamin Bark* (Works Manager of the Welsbach Light Company, Ltd.) then gave evidence. Questioned by the Chairman as to wages in this country, he said that they were adjusted by the Joint Industrial Council, and rose or fell in accordance with a rise or fall in the cost of living. There was also a system, arranged by the Joint Industrial Council, by which manufacturers employed learners. He explained that, if they employed girls with no knowledge of the business, those girls were absolutely useless for a time. Therefore, they did not earn the full rate of pay until after a period of six months. The minimum rate of wage for girls of 18 years or over was 6½d. per hour, which, for a full week of 48 hours, made a total wage of 26s. There was no maximum wage; this depending upon the efficiency of the individual worker. About 60 p.ct. of the workers in the Welsbach factory were on piece rates, and 40 p.ct. on time rates; the piece rates being arranged in order to allow the efficient worker to earn 25 p.ct. above the time rates. Labour costs amounted to about 35 p.ct. of the total cost of production of the mantle. But labour also entered into the costs of the raw materials, and he estimated that, if the labour involved in the manufacture of the raw materials used by mantle manufacturers was also taken into account, the cost of labour represented about 60 or 70 p.ct. of the total cost.

Miss *M. Harwood* (Forewoman, Messrs. Joseph T. Robin, Ltd.) confirmed Mr. Bark's evidence as to the minimum time rates and the 48-hour week. In Messrs. Robin's Factory, about 70 p.ct. of the girls were on time work and about 30 p.ct. on piece work.

Mr. *C. H. Wilcox* (Traveller, Messrs. Lighting Trades, Ltd.) said he had had fourteen years' experience in selling mantles, and found competition more severe than before the war.

Questions were put by Sir John Barran as to the margin of profit made by the wholesaler and retailer as between British and foreign mantles, and witness replied that this was arranged by the retailer and wholesaler. The wholesaler sold according to the profit he wanted; but if he sold British and foreign mantles at the same price, then he obtained less profit on the British than on the foreign. There was competition among British manufacturers.

Replying to Mr. Aiton, witness said that a wholesaler was sometimes satisfied with a profit of 4s. per gross on foreign mantles, and therefore sold to the retailer at a price below that at which the British manufacturer could sell to the retailer direct. The difference between the wholesale prices of foreign and British mantles went to the wholesaler and retailer in varying proportions.

Asked whether a mantle was used until it lost its luminosity, or whether it was destroyed, witness said that, generally speaking, it was destroyed.

Mr. *H. Talbot* (General Manager, Welsbach Light Company, Ltd.) then gave evidence, additional to that which he had given *in camera* with regard to costs of production. Since his appointment as Manager of the Welsbach Company he had found it difficult to keep the Company's Wandsworth factory employed with orders for gas mantles, in consequence of the unfair foreign competition to which the business had been subject. The year ended March 31, 1925, was probably the most difficult that he had experienced, and especially the last five months of that year. While the duty on German mantles under Part II. of the Safeguarding of Industries Act was in full operation, and after the stocks of imported mantles had been exhausted, there was a slight temporary movement in the British mantle trade; but the duty was allowed to lapse when the trade were beginning to reap some slight benefit from the Act. Unfortunately, also, imports of mantles from other countries increased as the German import figures decreased. Mr. Talbot then gave information with regard to wages, prices of raw materials, &c., which he had obtained in Germany in February of this year. He had visited both Germany and Italy. Labour costs, he said, represented about 35 p.ct. of the total production cost of a mantle, starting with the mantle manufacturers' raw materials; but he would not like to make a guess at the moment as to what percentage of the total cost, including the manufacture of raw materials, was represented by labour.

Asked why the prices of raw materials were higher in this country than in Germany, he said that one factor was the lower labour costs in Germany; and if this applied to the mantle industry, it must apply to the industries which made the raw materials. It was pointed out by the Chairman that ramie yarn was the same price in England and Germany; and one of the things that occurred to Mr. Talbot, in explanation, was that the raw material used by the German and British ramie yarn manufacturers came from the same source. He had no knowledge as to whether the price was an arranged one. In the case of other raw materials—except gas, which was a trifle cheaper in England than in Germany—the prices were higher in this country than in Germany.

Asked what duty he would suggest should be imposed on German mantles, Mr. Talbot said that the German manufacturer was getting an advantage over the British manufacturer, as shown by his figures, of 10s. per gross. He suggested that this should be the amount of the flat rate on German mantles; and that the rate should be higher on mantles from other countries.

Mr. MACASKIE, in reply to questions by the Chairman, said he was going to question the suggestion that the rates of wages in foreign countries were as low as it was said they were. He was also going to suggest that the prices of raw materials in Germany and in this country, as given by the applicants, were not accurate.

Mr. *Soper* said the figures the applicants had given were the current prices in this country.

In adjourning the proceedings until June 4, the Chairman said he wanted to give Mr. Macaskie every opportunity to rebut the evidence put forward by the applicants.

As to a suggestion that the Committee should consider the conditions in Germany and Poland only, and not in Austria and Italy, in order to shorten the inquiry, Mr. Soper asked whether the opponents would admit that the wages and conditions of employment were worse in Austria and Italy than in Germany and Poland. If the opponents admitted this, and the Committee found that conditions in Germany and Poland were unfair, then it followed that conditions in Austria and Italy were also unfair. Mr. Macaskie intimated that he was willing that the matter should be decided on German and Polish competition; Italy and Austria manufactured only 1 p.ct. of the mantles sold in this country.

The Committee decided to rule-out countries other than Germany and Poland.

SOUTH AFRICAN LIGHTING ASSOCIATION, LTD.

Annual Meeting.

The Thirty-sixth Ordinary General Meeting of the shareholders of the South African Lighting Association was held at No. 90, Cannon Street, London, E.C., on Wednesday, May 27. Mr. WILLIAM CASH (the Chairman of the Association) presided.

The SECRETARY (Mr. William Cash, Jun.) having read the notice convening the meeting, the minutes of the last shareholders' meeting held on May 28, 1924, and the Auditor's report on the accounts for 1924,

The CHAIRMAN moved the adoption of the Directors' report and accounts for the year to Dec. 31, 1924. In doing so, he said that the year 1924 had been both a disappointing and a difficult one, both for the Directors in London and for the officers at Port Elizabeth and Grahamstown. The report really summed-up the position during the past year, and the reasons why the results were not so good as they had hoped. Dealing first with the position at Grahamstown, he said the results were pretty much what had been anticipated. The municipal electricity undertaking was opened there in the middle of 1924, and it was unavoidable, of course, that the business of the Association would be affected thereby. On the whole, the results were not worse than the Association might reasonably have expected, having regard to their experience at Port Elizabeth and elsewhere, when electricity was first introduced, and where previously gas had had a monopoly of lighting and heating. For the whole year the consumption of gas was down only by 18 p.ct., but in the second half-year the decrease was larger than this; in the September quarter the consumption was down about 33 p.ct., and in the December quarter 40 p.ct. One satisfactory feature was that comparatively few of the consumers had given up the use of gas. The Association had lost only about 9 or 10 p.ct. of the consumers; but the public lighting had gone over to electricity. The street lamps had been disconnected, and the Association had incurred a certain amount of expenditure in doing this, though part of the expenditure had been recovered from the municipality. It had affected the business in that the profits in the fittings department showed a drop of some £300. On the other hand, the Association's officers had done all they could to save expense. The repairs items were considerably less in respect of both the works and the meters. The staff had been reduced, and the officials at Grahamstown were doing all they could—not altogether unsuccessfully—in pushing the use of gas for both cooking and heating. The net cost of coal there had been somewhat less, and labour costs were also down. Summing-up the whole position, it would be seen that the drop in profits on the year was about £2480; but £1000 was accounted for by the difference in the profits at Grahamstown, which had been unavoidable. The most unsatisfactory part of the position there was the subsidizing of the electricity undertaking by the municipality. They were carrying it on at a loss—a substantial loss. He need hardly say that competition of this sort was very unfair; but the Association had no control over it, and so far as the losses incurred on the electricity undertaking had to be borne by the rates, there was the still more unfair result that the Corporation injured the Association's business and yet asked the Association to contribute to the stabilization of their undertaking. With regard to Port Elizabeth, the Directors were disturbed and dissatisfied with the state of affairs out there, and had asked Mr. W. Arnott (who was Manager there for a number of years) to pay a visit to South Africa. They had asked him particularly to go into the question of the heavy leakage which had occurred, and which had been mentioned at the shareholders' meetings both by himself (Mr. Cash) and his predecessor in the chair for a number of years. Mr. Arnott (who was present at the meeting) had devoted himself particularly to the distribution side of the business, and had conducted an overhaul of the mains. He had also taken steps to cut off a large number of the old services which it was thought might possibly account for the leakage, and he had gone into the question of the meters again. The effect of this had been that the expenditure on repairs of works, mains, and meters had been exceptionally high. Mr. Arnott had not found anything so seriously wrong as to account for the high leakage. Mr. J. Donaldson, who was Manager there, had returned home. The Association had appointed a new Manager, Mr. P. C. Cleasby, who had arrived at Port Elizabeth in March. He had told them that further expenditure was necessary on some of the plant at the works. Port Elizabeth was said to be the most progressive town in South Africa, and Mr. Cleasby said that he saw no reason why the Association's business there should not double in the next ten or fifteen years. With regard to the price of gas, it was evident to the Directors that, for the last two or three years, in view of the expenditure which had been necessary in order to catch up arrears of works which had arisen during the war, it had been too low. They had determined that from July next the price must be raised. The Directors, as was shown in the accounts, after consultation with the Auditor had started a renewal fund. The Association had built up out of profits over a long series of years a reserve fund of £27,000. They had been building up a special renewal fund to deal with repairs of retorts on a definite and fixed basis, and this had reached a reasonable figure to meet the expenditure on retorts which occurred at infrequent intervals; this expenditure being heavy because of the necessity for sending material and labour from this country. In addition, the Directors had transferred the sum of £7000 from the general reserve, and had christened it a "renewal fund." It was felt that if they were faced—as at the moment they were—with a certain expenditure of an exceptional character, it was only reasonable and wise to charge that definitely to a renewal fund which had been built up out of profits. Mr. Cleasby had reported that, if this business was going to grow, the time was approaching when it would be necessary to do some expensive repair work to the two smaller holders at Port Elizabeth. In addition, certain of the other plant would need attention. It would be unfair that the necessary expenditure should fall on any one year; and provision had been made for it in advance. With regard to the other figures for the year, repairs of works, mains, and meters had been very heavy—nearly £1000 more than it was a year ago. Coal had cost less. On the other hand, the year had been unsatisfactory in connection with tar. The municipality, which used to take the tar for roads, were now using different material. The Association, however, were trying to meet this difficulty by treating the tar. Again, in order to induce people to take fittings, the Association had cut prices to a certain extent, and profits under that head were not so good. The year had also borne the expense of Mr. Arnott's visit to Port Elizabeth. All these things had conspired together to make 1924 a poor year. On the other hand, he felt—and he believed the shareholders would agree with him when they had heard Mr. Arnott—that there was no need to be in the least despondent about the undertaking. During the year, at Grahamstown they had lost 90 consumers out of 1130; at Port Elizabeth the ordinary consumers had increased slightly. As to dividend, the Directors were only recommending 5 p.ct. this year. In this undertaking, however, there was an advantage arising from the refund of income-tax, and the income-tax for the year on the whole dividend would be 2s. 3½d. in the £, as compared with the ordinary English rate of 4s. 6d. in the £. Thus, while they were really paying 5 p.ct., or a net dividend of £4 8s. 6d. p.ct., if it were an English dividend, subject to income-tax at 4s. 6d. in the £, the net dividend would be £3 17s. 6d.; the 5 p.ct. paid by the Association was, therefore, the equivalent of an English distribution to the shareholders, not of 5 p.ct., but of 5¼ p.ct., which would give a net return of £4 9s. 2d. p.ct.

Another matter to which the Chairman referred was the alteration on the Board. Mr. Henry Woodall, a brother of the late Sir Corbet Woodall, had been a Director of the Association since 1901. His services had been of great value to the Association, but he had asked to be relieved of his duties because of the difficulty of travelling to and from London. In these circumstances, the Directors had felt that it would be advantageous to the Association if they asked his nephew, Mr. Henry Woodall, Jun., who was the son of the late Sir Corbet Woodall, to become a Director. He was Chairman of several large English gas undertakings, and he had erected the Association's works at Grahamstown, so that he knew something of South Africa. When his firm were engineers to the undertakings, he had been in constant touch with all that went on in South Africa, so that he did not come to the Board without knowledge of the undertaking. The Association had been very fortunate in having persuaded Mr. Woodall, Jun.—who was a very busy man—to join the Board.

Finally, the Chairman said that the Directors had had a rather anxious and worrying year, and had done all they possibly could. Mr. Jesse F. Scott (Consulting Engineer), who wrote every week to Port Elizabeth and Grahamstown, and received reports from there every week, had done all that was humanly possible to see that the works were carried on to the best advantage. The leakage question, which had troubled the Board exceedingly, was a mysterious matter. Night tests had been taken, the plant examined, and a lot of money spent on overhauling meters. He expressed the hope that in the current year they would reap some substantial advantage from Mr. Arnott's visit to South Africa.

Sir CHARLES J. JESSEL, Bart., seconded the adoption of the report and accounts.

Mr. WILLIAM ARNOTT, reporting upon his visit to the Cape, said that when he was there they had overhauled, tested, and cleared from naphthalene as many of the principal mains as was practically possible; most of the testing for leakage being done at midnight. Several cases of broken mains and leakage of gas had been found. They had also opened-out and cut-off all old and disused service pipes and mains, which in many cases were in very bad condition and leaking. Some of them had been laid many years, and had rusted away by the action of the soil. Over 600 services had been cut-off at the main; and this should show good results this year in reduced leakage. In Port Elizabeth there had been a remarkable change for the better, which impressed one after seven years' absence. The town had gone ahead, and all around there were signs of prosperity, as shown by the number of good-class houses erected. There was a great future before Port Elizabeth as a manufacturing town, and before the Association in the increased supply of gas for cooking, water heating, and heating for manufacturing processes, which would have to be met by more gasholder storage, and by extending and increasing the size of the mains. Gas must be more advertised, as was being done in England; and new business must be canvassed for. It was there for the seeking. With a greatly increased output of gas, which should naturally follow, the actual amount of leakage would not be increased, but the percentage would be very much reduced. The small output of gas at Port Elizabeth for the large area supplied and the long length of mains in use (some 45 miles or so) made the leakage high in percentage, though small per mile of main. Mr. Sterley (the Local Secretary at Port Elizabeth) and Mr. Hart (the Local Secretary at Grahamstown) were both very keen workers in the interests of the Association, and were ideal Secretaries. The Association were fortunate in having two such men in charge of the financial side of the business, which, he could testify from personal experience, could not be in better hands.

Mr. R. W. LONG asked if the amount put aside for the renewal fund was likely to be sufficient to meet the cost of all repairs, or whether there was likely to be a further charge on the revenue in the future.

Dr. E. C. CARTER, speaking of leakage of gas, said he was glad to hear that it was due to faulty mains, and not to any stealing on the part of customers.

Mr. ARNOTT said there was not a single case of this.

Dr. CARTER, referring to the Chairman's remarks as to competition with electricity at Grahamstown, said that the capital sunk in the works at Grahamstown was not more than one-third of that sunk in the Port Elizabeth Works. He asked whether there was a competing electricity undertaking at Port Elizabeth, and suggested that, if there were not, then the Association might undertake the supply of electricity as well as gas. It always seemed to him that a gas company was one of the most suitable undertakings for taking on the supply of electricity.

The CHAIRMAN pointed out that the Corporation were supplying electricity at Port Elizabeth.

Mr. HAYES asked if there had been an opportunity for checking the meters for a complete quarter since Mr. Arnott had carried out the alterations to the mains and services, and, if so, what the result had been.

The CHAIRMAN, replying to the questions asked, said that a report had been received from the Engineer, who put the total amount that might possibly be spent on overhauling everything he could think of at something rather less than the amount transferred to the renewal fund, so that it could be taken that the £7000 in that fund would cover everything. There was also the balance of the retort renewal fund, which was another £2300, so that they were amply covered. In fact, he did not know that it would be really necessary to spend anything like this amount. With regard to electrical competition, the Association had been through that experience at Port Elizabeth, where for a time they had lost a very large proportion of the gas consumption; but this had now been regained. Grahamstown, however, was not growing in the sense that Port Elizabeth was. It was a residential, and not a business, community; so that it might take longer to restore the old position there. He added that Dominion coal had been used, but Mr. Cleasby proposed to use a more expensive coal, and one which would give a better yield. All these matters were continually before the Directors.

Mr. HAYES asked what was the present price of gas.

The CHAIRMAN replied that it was 7s. 8d. net per 1000 c.ft. at Port Elizabeth (8s. 4d. per 1000 c.ft., less discount).

Mr. HAYES commented that this was very low.

The CHAIRMAN agreed that it was low for a Colonial town, and was the lowest in South Africa. It was considerably below the price at Cape Town, where there was a much larger undertaking, and one which was better situated than that at Port Elizabeth.

Mr. HAYES, referring to the increased demand foreshadowed by Mr. Arnott in Port Elizabeth, asked whether the existing works were capable of meeting that increase.

The CHAIRMAN said the increased demand would mean expenditure on holders, and possibly on purifying plant. On the question of leakage, he added that, curiously enough, Cape Town suffered from a very heavy leakage.

The report and accounts were adopted.

DECLARATION OF DIVIDEND.

The CHAIRMAN proposed that a dividend of 5 p.c. for the year, subject to income-tax on the final dividend (2 p.c.) of 5¾d. in the £, less the interim dividend already paid (3 p.c.), be declared. He pointed out that on the backs of the dividend warrants there was a most complicated calculation which the Inland Revenue authorities insisted upon being put on the documents. The rate of income-tax for the whole year would be 2s. 3¾d., and the rate on the final dividend was only 5¾d. It was a difficult calculation, but it was necessary to put it on the warrants, because of the question of reclaiming tax to those shareholders who were entitled to a reclaim.

Mr. T. N. G. JENNINGS seconded.

The resolution was carried.

RE-ELECTION OF MR. HENRY WOODALL, JUN.

The CHAIRMAN moved that Mr. Henry Woodall, Jun., be re-elected a Director of the Association.

Sir CHARLES J. JESSEL, Bart., seconded.

The resolution was carried.

Mr. HENRY WOODALL, returning thanks, said he had been connected with the Association for a great many years, and it was a real pleasure to come back and to do what he could to serve them.

On the proposition of Mr. R. W. LONG, seconded by Mr. HAYES, Mr. Percival D. Griffiths, F.C.A., was re-elected Auditor, at a remuneration of 40 guineas.

VOTES OF THANKS TO OFFICERS AND STAFF.

The CHAIRMAN moved a resolution of thanks to the officials at the Cape. Mr. Sterley (Local Secretary at Port Elizabeth), an old and valued servant, was still there; Mr. Cleasby (Manager) had recently begun his work; and Mr. Hart (Local Secretary at Grahamstown) was continuing to give the really valuable service he had given for a good many years.

Mr. F. R. SMITH seconded, and proposed a vote of thanks to the Board. He also expressed his appreciation of the foresight of the Board in getting Mr. Henry Woodall, Jun., to join. Mr. Woodall, with his great experience, would be a source of great strength, and they all looked forward to better times for the Association.

The votes of thanks were accorded with acclamation, and the proceedings terminated.

Gas Meter Testing at Glasgow.—In his report on the work of the Gas Meter Testing Department for the year 1924, Mr. S. B. Langlands says that the number of meters tested was 39,035, and the amount of fees collected £2276. Of the total number of meters tested, 38,202 were new and repaired meters, and 833 were sent in by gas consumers for certification as to correctness.

Wiessoe Foundry and Engineering Company, Ltd.—At the fifth annual meeting of the Company next Friday, the Directors will report a net profit for the year ended March 31 of £19,281. With the sum brought forward, there is £24,121 available for distribution, out of which the Directors will recommend the payment of a dividend of 10 p.c., free of income-tax. This will absorb £20,000.

Bombay Gas Company, Ltd.—An extraordinary general meeting of the Company was held on May 27—Mr. W. G. Bradshaw, C.B.E., in the chair—for the purpose of confirming as a special resolution the extraordinary resolution passed at the extraordinary general meeting held on April 29 (*ante* p. 384). The Secretary (Mr. A. Dickson, jun.) having read the notice convening the meeting, the Chairman moved: "That each of the existing £5 shares be divided into five fully-paid-up shares of £1 each." Mr. H. H. Macleod (Deputy Chairman) seconded the motion, which was unanimously agreed to. The proceedings then terminated.

MONTEVIDEO GAS AND DRY DOCK COMPANY, LTD.

A Satisfactory Report.

The Fifty-Third Ordinary General Meeting of the Company was held last Wednesday, at Dashwood House, Old Broad Street, E.C.—Mr. FRANK H. JONES in the chair.

The SECRETARY (Mr. Henry Kearns) read the notice convening the meeting; and the minutes of the last meeting were taken as read as also were the report of the Directors and the statement of accounts.

The CHAIRMAN said he had to apologize for the absence of Mr. Charles Hunt (the Chairman of the Company) who was away. He would ask the Secretary to read a speech which had been prepared by Mr. Hunt.

The SECRETARY thereupon read the speech, which was to the effect that at the last meeting it was unfortunately necessary to draw attention to the indifferent results obtained from the Dock and Workshops Department. For the year under review, it was, however, gratifying to be able to report that the turnover therefrom had increased by no less than £22,012, though, as stated in the report, the resulting profit had been a comparatively small one. On the other hand, in the Gas Department the progress had been substantial, both from the selling and production points of view. As regards production, the installation of further beds of retorts and coal handling machinery had now been completed, and the whole of the retort-house plant and other machinery had been made more efficient. Moreover, the purification plant had been increased, and the overhaul of the mains, and the substitution of larger pipes, was being continued. This had had the effect of increasing the capital expenditure by £21,012, and the capital account was now overspent by £3719. That this expenditure was necessary, and had been wisely made, was proved by the increase in gas sales of 8¼ p.c., while the number of consumers had increased by 6·38 p.c. This showed that the better supply of gas now obtainable, and the improved pressures at which they were able to deliver it, had brought about a larger average consumption; and it would have been still larger had they not been obliged to supply a very rich gas in order to keep the consumers satisfied in those districts where the mains had not yet been dealt with. While dealing with this question of capital, the shareholders would be interested to know that, if the bank would continue to accommodate them, the Board were hopeful of getting through this year without recourse to the issue of new capital. Stocks were £6076 higher than in the previous year. This arose chiefly from the value of cookers on hire, which were becoming increasingly popular; and the Directors had reason to believe that the efficient stoves the Company supplied to the public, their cleanliness and ease of control, and the large reduction of labour which they secured in the household, would encourage many more to adopt them. It was still the aim of the Board to give the City of Montevideo, which was increasing rapidly, a really efficient and reliable supply of gas, as they were sure that this was the best means of securing a still larger number of consumers each year, and that it would lead to the adoption by them of other gas apparatus, both for the home and for manufacturing and industrial purposes. The stock of pipes also showed a considerable increase, but it was their policy to keep the works fully supplied, so that the work of enlargement could be energetically pushed ahead. The stock of coal on Dec. 31 was smaller in quantity, and fortunately lower in average cost, than at December, 1923. A further satisfactory feature of the accounts was that, though exchange showed a loss of £12,394, it was nevertheless a reduction on the previous year of £6950. The remittances from Montevideo were £17,000 more; but the average rate was 45·42d. per dollar as compared with 41·38d. in the previous year, and as the rate of exchange was now about 48d., the loss this year—if this higher rate was maintained—would be sensibly reduced. Although the revenue had increased by £41,036, the expenditure has increased by £43,775—reduced by the smaller loss on exchange to £36,825. Part of this increased expenditure naturally followed through the payment of additional wages and the cost of extra materials due to the increased business in both the Gas and the Dock Departments. Further, they had charged in the year's accounts the balance of the cost of renewals in connection with the damage suffered from the severe storm in July, 1923; and there had also been heavier expenditure chargeable to repairs and maintenance, owing to the enlargement of the mains, part only of which could be treated as capital expenditure. However, the balance of revenue account, at £41,592, showed an increase of £4,206; and after providing £6494 for depreciation of capital accounts, and £1521 for depreciation of cookers on hire, they had been enabled to transfer £4500 to deferred maintenance, in which was included an amount towards the cost of the gasholder to be erected in the current year. They were commencing the shipment of the materials this month; and when the erection of the holder had been completed—which it was hoped would be in time for next year's winter season—the Board believed that the additional storage would tend to more economical working, and extend the life of the retorts, which at present had to be fired-up and let-down to suit the varying demands, which were very heavy at certain times of the day, and slight at others. The consequent wear and tear was therefore considerably more than if more regular working could be secured. It was not easy to forecast the results for the current year. So far this year the Dock Department, which was always a very fluctuating business, had secured a satisfactory share of the work to be executed, and had been fairly well employed. The number of gas consumers continued to increase, and a satisfactory number of additional cookers had been fitted each month. Residuals, which last year gave an excellent increase, compared with the year 1923, would, it was feared, not be so satisfactory. Coal was now being sold in Montevideo at very low prices. As the value of coke depended in a large measure upon the selling price of coal, the revenue obtained for this residual showed a reduction compared with the early months of 1924; but it was to be hoped that the competition would be less severe, and that coal would be sold at prices which yield a fair margin of profit. They could, of course, use their coke, and produce a larger quantity of water gas; and this would obviate throwing it upon the market at an unremunerative price. The plant

and property had been maintained in a very efficient condition; and the extension of the plant was sufficient to meet a considerable increase in output. With regard to their former General Manager, Mr. T. F. Lane, who was elected to the Board on his retirement, the Directors regretted that he had been obliged to relinquish his seat, as he had found it impossible to take up his permanent residence in this country. It was not proposed to fill this vacancy, but to carry on with four Directors as formerly; and the fees would be proportionately reduced.

The CHAIRMAN moved the adoption of the report and accounts; and this was seconded by Mr. JOHN MEWS, LL.D.

Mr. C. C. MALLET said he had recently had an opportunity of seeing the works; and what had struck him more particularly was that, owing to the advancement of Montevideo, the Company's freehold land possessed immense value. He reckoned the site alone was worth about two-thirds of the capital of the Company. He also desired to refer to the good work of the employees. He met Mr. J. N. Whyte (the Engineer and General Manager), Mr. J. S. Ryan (the Superintendent of the Dock Department), and Mr. D. C. Clark (the Engineer-in-Charge of the gas-works), and found them all most zealous in the Company's interests. The report was a very good one, in the circumstances which existed in the River Plate and in the gas industry.

Mr. HOWEL J. J. PRICE also congratulated the Board on the excellent character of the report and balance-sheet.

The report and accounts were unanimously adopted; and a dividend on the ordinary stock was declared, for the half-year to Dec. 31, of 2 p.ct., free of income-tax, making, with the interim dividend, 4 p.ct., free of income-tax, for the year.

Mr. John Mews was re-elected a Director, on the proposition of the CHAIRMAN, seconded by Mr. W. EDGAR HORNE; and the Auditors (Sir Laurence Halsey and Mr. William C. Sneath, partners in the firm of Messrs. Price, Waterhouse, & Co.) were re-appointed, on the motion of Mr. CLIFFORD H. HUNT.

The CHAIRMAN proposed that the best thanks of the meeting be given to the officers, staff, and workpeople, both here and in Montevideo. All did their very best for the Company.

This was seconded by Mr. MALLET, and acknowledged by Mr. KEARNS.

The proceedings concluded with a vote of thanks to the Chairman and Directors, which was proposed by Mr. PRICE, and seconded by Mr. HUNT. The mover voiced the regret of the shareholders at the absence of Mr. Charles Hunt.

WORTHING GAS COMPANY.

Special Order to be Applied For.

An extraordinary general meeting of the Worthing Gas Light and Coke Company was held on May 23 for the purpose of approving application for a Special Order, under section 10 of the Gas Regulation Act, to enable the Company, among other things, to extend their area of supply.

Mr. WILLIAM CASH (Chairman of Directors) said that the real object of the Order was to enable them to extend their area of supply. They had had in the past, on many occasions, requests to take a supply into the parish of Findon; but as this was beyond their statutory area, it was necessary for them to extend their area by a Special Order. As they were making this application, the Directors thought they would take the opportunity of bringing some of their regulations up to date, and slightly amending some of the provisions of the Act of Parliament of 1907, which were mainly administrative, in connection with the Company. The time by which local authorities could lodge objections to their application had not yet expired, but he did not think it likely that they would meet with serious opposition. The Chairman then proceeded to refer to the various clauses in the application, and in referring to that concerning the parish of Ferring, he pointed out that this parish was within the area of supply of the Littlehampton Gas Company, but they were not attempting to do anything inimical to the interests of the Littlehampton Company if they were prepared to give a supply. They had been asked to go there and give a supply to the parish. Mr. Cash also pointed out that they were seeking powers to raise additional capital. In regard to the price for supply at Findon, he said that for the first five years it was proposed to charge 2·4d. per therm above the price ruling for the time being at Worthing. They were seeking to be empowered to pay interim dividends. There was another clause dealing with pensions.

The CHAIRMAN then moved that approval be given to the application. The DEPUTY-CHAIRMAN seconded, and the motion was unanimously approved.

Visit to the Works of Messrs. Peebles & Co., Ltd.—Members of the Glasgow Corporation Lighting Association, to the number of 60, visited the works of Messrs. Peebles and Co., Ltd., Toy Works, Bonnington, Edinburgh, on Saturday, May 30, and made an exhaustive inspection of the manufacturing operations in connection with meters and gas governors. The visit proved of great interest, and was much appreciated. Mr. S. B. Langlands, Hon. President of the Association, and Inspector of Lighting for Glasgow, accompanied the party. After the visit the firm entertained the party to luncheon.

"S.B.G.I." Golf Challenge Bowl.—Fourteen members of the British Gas Industries Golfing Society took part in the competition at Sundridge Park on Tuesday, May 19, for the Yates Challenge Bowl, which was presented several years ago by Mr. H. James Yates (Chairman of Radiation, Ltd.). The winner was Mr. C. A. G. Thomas (E. & J. Pearson, Ltd., of Stourbridge). Mr. R. P. Chester was second, and Mr. H. M. Thornton (Director of Radiation, Ltd.) was third. One of the Past-Presidents of the Society, Sir Arthur Duckham, entered for the competition, but at the last moment was prevented from attending.

EASTBOURNE GAS COMPANY.

Proposals for raising additional capital in order to cope with increased business were submitted by the Directors of the Eastbourne Gas Company at an extraordinary general meeting of the stockholders, held on Thursday, May 21.

DIRECTORS' PROPOSALS

The following resolution was submitted:

"That the Directors be empowered to issue the remainder of the authorized capital (stock) amounting to £38,590 either as ordinary B stock or as 5 p.ct. preference stock, or partly as one of those stocks and partly as the other of them, and at such time or times and in such manner as the Directors shall deem best."

Also, "That the Directors be further empowered to issue the authorized loan capital (at present unissued) amounting to £79,167 as mortgage bonds, debentures, or 5 p.ct. debenture stock, or partly in one and partly in the other or others of those ways, and at such time or times and in such manner as they deem best."

The CHAIRMAN (Mr. Caleb Diplock) formally moved the resolution.

REASONS FOR FRESH CAPITAL.

The DEPUTY-CHAIRMAN (Mr. Frank H. Jones), after saying that he had much pleasure in seconding the resolution, explained the purpose of the meeting and the need for raising fresh capital. Parliament had said—and the Company could not act without such sanction—that the Company could raise £117,757—£38,590 as ordinary stock, and the balance as loan capital—and the Board were asking the stockholders to give them the necessary authority to do so. The Company had not raised any new capital for many years. When requiring money their practice had been to obtain loans from the bank, and at the present time they owed the bankers about £22,000. The balance-sheet for last year showed about £5500 invested in Consols in respect of the reserve and special purposes funds, and liabilities to those funds of just over £17,000. The Board had two things to do: First, to repay the money borrowed from the bank; and, secondly, to strengthen the reserve and special purposes funds by investing them, instead of sinking them entirely or largely in the undertaking itself. The money that came from this special appeal would therefore be used for the two purposes mentioned, and the investments in respect of the reserve and special purposes funds would be in first-class securities. More capital was naturally wanted in a fast-growing undertaking. To give them some idea of the extent of their business, he mentioned that gas was used in practically every house in Eastbourne—certainly in every house that the gas mains passed. The quantity of gas sold last year showed an increase of 6½ p.ct. on the previous year. This year, up to the present, that increase had been maintained. The strength and growing character of the business were further indicated by the showroom sales of stoves, cookers, fires, and lighting fixtures, which amounted last year to £12,000.

After the stockholders had given their sanction, they would receive an offer to subscribe £50,000 of 5 p.ct. debenture stock. The fact that the Eastbourne Gas Company had never had any loan capital was almost unique among gas companies.

The CHAIRMAN put the resolution to the meeting, and it was carried unanimously.

Blackburn Gas Undertaking.

The annual report of the Blackburn Gas Engineer, Mr. G. P. Mitchell, states that the total quantity of gas made during the year was 1004 million c.ft.—an increase of 55,565,000 c.ft., or 5·85 p.ct. over last year. The total number of gas cooking and heating appliances in use at the close of the year was 46,879, compared with 43,805 last year. The demand for these appliances, states Mr. Mitchell, has been maintained throughout the year. The total revenue was £291,204—a decrease of £0062, consequent upon a reduction of 3d. per 1000 c.ft. at the beginning of the year. The gross profit was £61,083, and the net profit £2486. An additional contribution of £1610 had been made for the extinction of the 4 p.ct. stock. The Engineer records that the demand for gas during the last six years has increased by approximately 270 million c.ft., or 36½ p.ct. The new showrooms in King William Street would shortly be ready for opening. The rateable value of the undertaking had been increased from £12,635 to £19,000, which would mean an additional payment to rates of £4050, equal to a charge of 1·05d. per 1000 c.ft. sold.

Lecture at Brighton.—At a meeting of the Brighton and Hove Rotary Club on May 27 Mr. C. H. Rutter, M.Inst.C.E., Engineer and General Manager of the Brighton and Hove General Gas Company, gave a lecture on "A Century of Gas Making," in which he dealt with the development of the industry and of the Brighton Gas undertaking, and gave a brief outline of the process of manufacture.

Charges for Gas Down to Pre-War Level.—At the last meeting of the Leek Urban Council reductions in the charges for gas to ordinary consumers were sanctioned—viz., "that as and from the date of the reading of the meters for the quarter ended March, 1925, the price of gas to ordinary consumers in Leek be reduced from 3s. 0d. to 3s. 6d. per 1000 c.ft., less a discount of 6d. per 1000 c.ft. for prompt payment; and that the price to ordinary consumers at Rudyard be reduced from 4s. 9d. to 4s. 6d., less a similar discount of 6d. Further, that the discount allowed to prepayment consumers in Leek be advanced from 5d. to 8d. per 1000 c.ft., and to prepayment consumers in Rudyard from 4d. to 7d. per 1000 c.ft." These revised charges for gas will bring it down to the pre-war level. Reviewing the year's working, the Chairman, Mr. N. A. Furmston, stated that considerable developments had been carried out at the gas-works, and the results had exceeded their expectations. The net loss on the year's working was about £1900; but this was largely due to the policy of spending as much as possible out of revenue and reserve fund, instead of borrowing at high rates of interest. On March 31 the reserve balance stood at £11,500.

TRADE NOTES.

Drakes' Verticals.

Messrs. Drakes, Ltd., of Halifax, in a folder bearing the title of "Vertical Retorts of Distinct Individuality," describe the main features in their form of setting. The folder is one of a series which the firm are issuing.

The "Becco-Legg" Measuring Gear.

A new list has been published by the Becco Engineering and Chemical Company, Ltd., of Nos. 158-160, City Road, London, E.C. 1, in which they describe the "Becco-Legg" plant "XL" water measuring and reagent apportioning gear, which is suitable for all makes of water softeners and purifiers using lime, lime and soda, chalk, alum, barium, carbonate, or other reagents.

"Talisman" Oils.

Messrs. Trier Brothers, Ltd., of No. 36, Victoria Street, Westminster, have published lists of their new "Talisman" oils for motor vehicle lubrication, collieries, and general industries, and their "T.B." grease cartridges. The firm claim that "Stauffer's Lubricant," of which they have been sole makers for more than forty years, represents the standard of excellence in grease lubrication.

New Plant at Blackburn.

The Blackburn Town Council have confirmed contracts with Messrs. R. & J. Dempster, Ltd., of Manchester, for the supply and erection of one four-lift spiral-guided gasholder, with steel tank, and one two-lift spiral-guided holder, with steel tank, at the Greenbank Gas-Works; and a carburetted water gas plant at the same works to be supplied and erected by Messrs. Humphreys and Glasgow, Ltd., of London.

Blackman Fans.

The higher the temperature in workshop, factory, mill, foundry, office, restaurant, theatre, or any other public building, the greater the necessity for Blackman ventilating fans, state the James Keith & Blackman Company, Ltd., of 27, Farringdon Street, E.C. 4, in an illustrated pamphlet which they have just issued. These fans keep the atmosphere clear and healthy, and blow in or induce a continuous supply of fresh air.

"Asbestone" Patterned Sheeting.

This widely known brand of asbestos-cement sheeting is now available with attractive patterns impressed for use as fire surrounds, &c. These sheets are of handsome appearance, and are substantial in thickness. They are easy to cut and fix, and can be coloured to tone with decorative schemes. The material does not leave the impression of ugly uniformity, but has slight irregularities in texture which afford a genuine tile effect—the more so when a transparent colouring is applied. Moreover, "Asbestone" patterned sheets are inexpensive; and numerous gas undertakings are fitting this material as an economic substitute for tiled and metal fire surrounds. The manufacturers, The Cellactite Works, Ltd., of Higham, Kent (London Office and Showrooms: Lincoln House, Nos. 296-302, High Holborn, W.C. 1), have published a booklet which describes this material, and which will doubtless be of interest to gas undertakings.

CONTRACTS OPEN.

Coal.

The Gas Committee of the Borough of East Retford are prepared to receive tenders for about 9000 tons of gas coal, nuts, peas, and slacks. [See advert. on p. 686.]

The Directors of the Peterborough Gas Company are inviting tenders for the supply of 16,000 tons of best screened gas nuts. [See advert. on p. 687.]

The Gas Committee of the Corporation of Belfast are requiring tenders for the supply of 170,000 tons of best gas coal. [See advert. on p. 687.]

Tenders are invited by the Audley Urban District Council for the supply of screened gas coal. [See advert. on p. 686.]

Steel Mains.

The Gas Department of the Pontypridd Urban District Council are inviting tenders for the supply and delivery of steel mains. [See advert. on p. 686.]

Tar.

Tenders are invited by the Lancaster Corporation for 300 tons of tar produced at their gas-works. [See advert. on p. 686.]

General Stores (Iron and Steel, Castings, Shovels, &c.).

The City of Leeds Gas Committee are inviting tenders for the supply of general stores and iron castings. [See advert. on p. 686.]

Pipes and Specials.

Tenders are invited by the Gas Committee of the Marple Urban District Council for the supply of gas mains and specials. [See advert. on p. 687.]

The Bradford Corporation gas showrooms, in Darley Street, have drawn large crowds lately to inspect a magnificent window display of prizes for competition at the annual Bradford Police Sports.

The Lytham St. Annes Council have referred back to the Committee a suggestion that gas should be reduced in price. The Engineer (Mr. J. H. Ranft) recommends that the present price of 10·8d. per therm be retained, but that a sliding-scale of discounts be adopted.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

The inland coal trade of Yorkshire and Lancashire is suspended owing to the holidays. Gas coal contracts should now be undergoing completion, but in many instances this cannot be done, most works preferring to carry on their obligations and to take coal purchased and not delivered. It is not expected that the gas coal market will be good until September or October.

There is still a deadlock in the shipping trade, particularly as far as Yorkshire is concerned. Collieries are being asked to quote for supplies from Sept. 1, but are reclining, and the market is dead.

There is a feeling that more industrial fuel will be required as from July 1 next; but nothing definite can be assumed either by colliery owners or consumers. Prices are ruling very low for "spot" market sales; but buyers are reluctant to take up any quality that may be available.

In Lancashire last wek a moderate amount of business was done in industrial fuel, and there was a fair demand for first-class Lancashire slacks.

The approximate prices at Hull for prompt loading f.o.b. usual shipping ports are: South Yorkshire—Association (hard), 19s. 6d.; screened gas coal, 17s. 6d. to 18s.; washed trebles, 18s. 6d. to 19s.; doubles, 16s. 6d. to 17s.; singles, 15s. 6d.; smalls, 11s. to 11s. 9d.; unwashed doubles, 16s.; rough slack, 10s. to 10s. 6d.; smithy peas, 18s. 6d. to 20s. West Yorkshire—Hartleys, 16s. 6d. to 18s.; screened gas coal, 16s. 6d. to 18s.; washed trebles, 17s.; doubles, 14s. to 15s.; singles, 13s. 6d. to 14s. 6d.; smalls, 11s.; unwashed trebles, 16s. to 16s. 6d.; doubles, 12s. to 13s.; rough slacks, 9s. 6d. to 10s.; coking smalls, 8s. 6d. to 9s. Derbyshire and Notts.—Top hards, 19s. 6d.; washed trebles, 17s. to 18s.; doubles, 16s. to 16s. 6d.; singles, 15s. to 15s. 6d.; smalls, 11s.; unwashed doubles, 14s. to 14s. 6d.; rough slack, 9s. 9d. to 10s. 6d.; gas coke, 19s. to 21s.; furnace coke, 15s. 9d. to 16s. 9d.; large screened steams for bunkers, 15s. to 17s. per ton.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Notwithstanding the shrinkage of demand, the output of Midland pits was maintained at a fair average during May. Collieries are putting forth great efforts to keep pits going through the slack season, and are offering contractors very low terms conditionally on their taking "the fat and the lean" in equal weekly consignments. These offers apply to June and July. With the co-operation of the consumer the difficulties of autumn and winter supplies might be very considerably minimized. Current buying is mostly on hand-to-mouth lines, however, though stocks might now be laid in at a cost which would show a handsome saving when compared with those which in the nature of things must prevail later. The consumer will not understand that the effect of holding off the market is to cause stringency when the normal autumn demand sets in, and collieries must then balance the account by making use of a favourable market position for all it is worth. A Birmingham merchant who sent out 3000 circulars urging customers to place their orders during the summer and offering them the full advantage of lower pithead prices received no response whatever in the case of 2996 of them. The regular summer prices notified show reductions of 1s. to 2s. a ton on rates lately ruling; but consumers who are willing to facilitate business by taking convenient deliveries in bulk can get much larger concessions. There has been little work at the pits this week.

Sandy Gas Exhibition.—The Directors of the Sandy Gas Company recently held a gas exhibition, in conjunction with Messrs. R. & A. Main, Ltd., in the Conservative Hall, Sandy. Lectures and cookery demonstrations were given each afternoon and evening by Miss Anstice M. Strick, M.C.A. These attracted large and appreciative audiences. A representative selection of the manufactures of Messrs. R. & A. Main was arranged round the hall.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *May 29.*

The market for pitch is quiet; and although a certain amount of interest is being displayed in next season's shipment, the prices suggested by buyers are very low and not tempting to makers. The market is nominal at about 41s. to 42s. per ton.

The demand for road tar continues strong.

Creosote remains steady at about 7d. to 7⅛d. per gallon.

Solvent naphtha is firm at 1s. 8d. to 1s. 9d. per gallon for 95-160 quality. Pure benzole and pure toluole are about 1s. 11d. to 2s. per gallon.

Tar Products in the Provinces.

June 2.

There has been very little change in tar products during the past week.

In pitch there have been one or two sales reported for the forward position; but foreign buyers' ideas are lower than the tar distillers are generally willing to accept for the forward position.

Creosote is steady.

In water white products there is no change.

The average values for gas-works products during last week were: Gas-works coal-tar, 26s. 3d. to 31s. 3d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.c., North, 1s. 7¼d. to 1s. 8¼d.; crude, 65 p.c.t. at 120° C., 11d. to 1s. 1d., naked at makers' works; 50-90 p.c.t., naked, North, 1s. 7¼d. to 1s. 8¼d. Toluole, naked, North, 1s. 6½d. to 1s. 7¼d., nominal. Coal-tar crude naphtha, in bulk, North, 7¼d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 5⅜d. to 6d.; salty, 5⅛d. to 5⅜d.; Scotland, 5¼d. to 5⅜d. Heavy oils, in bulk, North, 6¼d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality, 2½d. per minimum 40 p.c.t., purely nominal; "B" unsaleable.

BRITISH SULPHATE OF AMMONIA FEDERATION PRICES.

The British Sulphate of Ammonia Federation, Ltd., in announcing their prices for the 1925-26 season, write:

"You will observe that, in spite of the heavy reduction in price which we have decided to make, though there has been no material decrease in the price of our chief raw material, sulphuric acid, nor in our other costs of production, we have made no alteration in the amount of the commission allowed to recognized distributors. We have refrained from reducing the commission because we are anxious not to do anything which might hamper the distribution, and therefore discourage the use, of sulphate of ammonia at a time when agriculture is but slowly recovering from an acute crisis, and while British consumption of fertilizers generally is still far below the level already reached by progressive agricultural communities in other countries. It is understood that quantities purchased at the price stated below will be used for home agricultural purposes only. Prices for later months will be announced later; but we are prepared to quote for forward delivery now on application.

"We offer to sell sulphate of ammonia for home agricultural use at the following prices: For June, July, and August delivery, £12 5s. per ton for neutral quality in fine friable condition, free from lumps, basis 21·1 p.ct. nitrogen. Delivered to consumer's nearest station or wharf in Great Britain, for prompt cash payment, in lots of four tons and upwards."

Lea Bridge Capital Issue.—The £30,000 of 6 p.ct. preference stock of the Lea Bridge District Gas Company issued by Messrs. A. & W. Richards, on behalf of the Directors, was considerably oversubscribed at prices ranging from £107 down to the minimum of par.

Price of Gas at Truro.—The Truro Mercantile Association have decided to ask the Truro Gas Company to consider the matter of reducing the price of gas. Mr. J. H. Broach, who introduced the question, said they were at present paying 1s. 4d. per therm, which was equal to 6s. per 1000 c.ft.

Gas Mantles Committee.—The Committee appointed by the President of the Board of Trade to inquire into, and report upon, the application made by the Incandescent Mantle Manufacturers' Association for the imposition of a duty upon gas mantles, will hold a further public sitting for the purpose of taking evidence at 10 a.m. on Thursday, June 4, at the Board of Trade, Great George Street, S.W. 1.

Increased Price at Coventry.—The Coventry Corporation have decided to increase the price of gas by 3d. per 1000 c.ft. to prepayment meter consumers and 4d. per 1000 c.ft. to ordinary consumers. Bulk consumers above 7,500,000 c.ft. per quarter are to pay an increase of 3d. per 1000 c.ft. The reasons given for raising the price are an estimated deficiency of £19,800 on the year's working, owing to increased wages and the decrease in the value of tar products and the slump in the market for gas coke.

Padiham Gas Undertaking.—The Padiham Urban District Council have received a letter from the Ministry of Health requesting to be furnished with the Council's observations on the Assistant Auditor's report on the gas-works finances, and stating that the Ministry, in the present instance, in view of the financial position of the undertaking, would be prepared to entertain an application for sanction to borrow money in respect of the completed works. The Council, however, decided that they did not consider it desirable that the money should be borrowed; and the Clerk was instructed to reply to the Ministry accordingly.

Issue of 5 per Cent. Debenture Stock.

THE

EASTBOURNE GAS COMPANY.

(Incorporated by Special Act of Parliament 1868.)

DIRECTORS:
MR. CALEB DIPLOCK (*Chairman*).
MR. FRANK H. JONES, C.E. (*Deputy-Chairman*).
MR. BENJAMIN BRADFORD.
MR. HOWEL J. J. PRICE, D.L., J.P.
MR. CLEMENT JOHN VINALL.
MR. F. ELIOT WILLIAMS, O.B.E.

RESIDENT ENGINEER AND WORKS MANAGER:
MR. WILLIAM H. HAMMOND.

SECRETARY: MR. JAMES S. GARRARD, F.C.I.S.

AUDITORS: MESSRS. JAMES WORLEY & SONS, Chartered Accountants, London and Eastbourne.

BANKERS: BARCLAYS BANK LIMITED.

THE DIRECTORS OFFER FOR SALE BY TENDER

£50,000

5 per Cent. DEBENTURE STOCK.

The Minimum Price at which Tenders will be received is £95 per cent.

A deposit of £10 per £100 must accompany a tender, and the balance of the purchase money is to be paid by 30th June, 1925.

The Stock will carry Interest from the 1st July, 1925, and will be payable half yearly on the 1st January and 1st July.

The Stock will be registered in the Company's books and the certificates issued in the names of the purchasers or their nominees free of expense.

The Company has been incorporated for nearly 60 years, and its powers have been added to from time to time by successive Acts of Parliament, and, more recently, by Orders under the Gas Regulation Act, 1920.

The Statutory area now covers not only Eastbourne, but extends to the market town of Hailsham, together with Hellingly, Horsebridge, Westham, Hankham, Pevensey Bay, Willingdon, Wannock, Jevington, East Dean, and Polegate.

This growth of the Company's operations has necessitated considerable works extensions and the laying of many miles of mains.

The following Table indicates the Growth of the concern:

Year.	Number of Gas Consumers.	Gas Sold, Millions.
1904	7,345	353
1909	9,423	449
1914	11,365	511
1919	11,957	528
1924	13,371	555

The Authorized Capital of the Company is	**£364,000**	**0**	**0**
Of which there has been issued	325,409	11	2
Remaining to be issued	£38,590	8	10
The Authorized Loan Capital is	**£79,167**	**0**	**0**

These powers have not hitherto been used; this is the first issue of Loan Capital.

As is generally known, this Company enjoys the reputation of working upon a very low Capital; and consequently occupies a strong position financially.

This additional Capital will still leave the Company in an enviable position with respect to the amount of Capital employed as compared with similar Companies.

The Reserve and Special Purposes Funds of the Company amount to £17,114.

The amount at Credit of Profit and Loss Account is £15,834, after payment of the half-yearly dividend on the 6th March last.

Tenders for the Stock must be sent in not later than Monday, 8th June, 1925, and in the event of the receipt of Tenders for a nominal amount of Stock exceeding £50,000, Tenders at the lowest price accepted will, as far as possible, be subject to a *pro rata* diminution.

If no allotment is made, the deposit will be returned in full, and in case of partial allotment, the balance of the deposit will be applied towards payment of the remainder of the purchase money.

The Stock will be registered, and will be transferable by deed in the usual way in amounts or multiples of £50, as soon as it is fully paid.

Interest at 10 per cent. per annum will be charged on balances not paid on the due date (30th June, 1925).

Application will be made in due course to the Committee of the Stock Exchange to allow dealings in the Stock now being issued.

Copies of this Prospectus and Forms of Tender may be obtained at the Company's Offices, 87, Terminus Road, Eastbourne.

By Order of the Board of Directors,
CALEB DIPLOCK,
Chairman.

87, Terminus Road, Eastbourne,
1st June, 1925.

Tenders to be forwarded to the Secretary, Eastbourne Gas Company, in a sealed envelope marked "Tender for Debenture Stock," not later than Monday, 8th June, 1925.

The minimum amount of Stock which may be tendered for, or will be allotted, is £50 or multiples thereof.

The Stock will be registered in the Company's Books, and the Certificates issued in the name of the allottee or his or her nominee, free of all expense.

STOCK MARKET REPORT.

Ignoring the allurements of the Derby and the excitement over the Stock Exchange sweepstake, the chief feature of the Stock Markets last week was the failure of the 5 p.ct. New South Wales Loan. As we indicated last week, the more generous terms, as compared with the two previous large issues of trustee securities, were expected to attract investors, and the result, which left 68 p.ct. with the underwriters, is difficult to understand. It would be gratifying if it were clear that the monies are being used for trade expansion. Reports from industrial centres, however, though hopeful, do not appear to justify this interpretation, as the poor response is not confined to trustee securities; the underwriters of the ordinary and preference shares of Henry G. Lewis & Co. being left with about 80 p.ct. of the issue. Dealings in the new loan were recorded at $\frac{5}{16}$ discount. Some hopes are expressed of improvement in prices this week on the distribution and investment of the War Loan dividend, and the Gilt-Edged Market was steady in consequence.

Quotations at :—*a*,—Bristol, *b*,—Liverpool, *c*,—Nottingham, *d*,—Newcastle, *e*,—Sheffield. * Ex. div.

In the Foreign Market German 7 p.ct. were marked up ¼ to par, and French Bonds were a little better. Home Rails continued a friendless market. There were some uncertain movements in the Oil Market, which will not be improved by the rumours in certain quarters of a possible reduction shortly in the price of both crude oil and petrol. Rubber shares, due to a further improvement of the raw material, which now stands at 2s. 10¾d. per lb., were buoyant, and several appreciable increases occurred in the quotations.

The Gas Market was quieter than usual. There were fewer transactions recorded, and the only quotations varied on the London Exchange were a further fall of 3 points on Imperial Continental Ordinary, and a rise of 6d. on the Primitiva Ordinary. An addition to the List is made this week by the inclusion of the Tottenham and District £150,000 5½ p.ct. Preference Stock.

The following transactions were recorded during the week:

On Monday, Bombay 5⅛, Bournemouth "B" 12⅛, Brentford "A" 96, Commercial 4 p.ct. 88, Continental Union 36, European 7, 7⅛, Gas Light and Coke 83⅞, 84¼, 4 p.ct. preference 79¾, 80, 3 p.ct. debenture 61¼, 61½, Imperial Continental 154⅛, 155 *ex* div., Montevideo 67½, Primitiva 4 p.ct. debenture (1911) 65½, South Metropolitan 3 p.ct. debenture 60½, Tottenham "B" 95.

On Tuesday, Bournemouth "B" 12⅛, Commercial 4 p.ct. 87, Croydon maximum dividend 83½, Gas Light and Coke 83⅛, 84⅛, 84¼, 3½ p.ct. maximum 64, 4 p.ct. preference 79½, 3 p.ct. debenture 60⅜, 61, Imperial Continental 154 *ex* div., Montevideo 68, Primitiva 9s. 7¾d., 9s. 9d., San Paulo 6 p.ct. preference 8⅛, 8⅛, South Metropolitan 6¼ p.ct. debenture 104. Supplementary prices, Hornsey 4 p.ct. debenture 75, Montevideo 5 p.ct. 1st mortgage debenture 75.

On Wednesday, Bournemouth "B" 12½, 12⅛, 6 p.ct. preference 11½, 11⅝, Brentford "A" 97, Continental Union 7 p.ct. preference 91½, Gas Light and Coke 83½, 83⅜, Imperial Continental 154 *ex* div., Oriental 104½, 105, Primitiva 9s. 6d., 9s. 7¾d., 9s. 9d., South Metropolitan 93⅛, 94¼, 94½, 6¼ p.ct. debenture 104, Wandsworth "B" 113¼.

On Thursday, Brentford "A" 95¾, "B" 96, Commercial 4 p.ct. 87, Continental Union 35¼, Croydon sliding-scale 99½, 99⅞, 100⅛, Gas Light and Coke 83⅛, 83⅜, 84, 84¼, Imperial Continental 153, 155 *ex* div., Primitiva 9s., 9s. 4½d., 9s. 9d., 9s. 10½d., 10s., South Metropolitan 93⅜, 94⅛, Tottenham 5⅛ p.ct. preference 104¼, Wandsworth "B" 112½. Supplementary prices, Hornsey 4 p.ct. debenture 76½.

On Friday, Commercial 4 p.ct. 86, Croydon sliding-scale 99¼, 99⅝, 100⅛, Gas Light and Coke 84⅞, 84¼, 3½ p.ct. maximum 63, 63⅜, 63⅞, Hastings and St. Leonards 3½ p.ct. 75¼, 75⅜, Imperial Continental 151, 152, 153, 154 *ex* div., South Metropolitan 93¾, 94⅛, South Suburban 96.

In Lombard Street money was considerably easier, and a further general decline occurred in both loan and discount rates. The charge for renewing day-to-day loans after touching 4½ p.ct. finally closed at 4 and 3½ p.ct. The Treasury Bill average rate dropped a little over 3s. 1d. on the week to £4 6s. 4'48d. p.ct.

In the Foreign Exchange Market French francs were erratic, and at one time touched 97.45, finally closing at 96.90. Belgian exchanges as usual rose in sympathy, and closed at 99.25. Italian lire, on the other hand, appreciated slightly, and closed on Friday at 121.69. Sterling was generally firm; and on Thursday touched the highest price since the war. The week closed at 4.86⅛.

Silver was firm on Indian support at 31⅜d. per oz. There was no gold available, the price nominally being 84s. 11½d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3½ p.ct. at notice.

Demy 4to. Limp Cloth. Price 10s. 6d.

INSTITUTION MEETING

A complete account of the week's proceedings will appear in the single issue of the "JOURNAL" published on June 17.

EDITORIAL NOTES.

The Institution Meeting.

gorgeous weather similar to that experienced last eek favours the present one, nothing will be wanting complete the success of the annual meeting of the In- itution. The programme is a full one; and the records headquarters show that the members are entering thusiastically into every item. From beginning to end, e predict (given good weather) complete satisfaction on e part of all who will be taking part in the week's events. here is one matter to which reference may be made. rough the stress of the times and the many occupations our busy men, the MS. of some of the reports and pers which are being presented at the meeting was mewhat belated; and then the intervention of the Whit- n holidays caused further delay to the work of revision d printing. It is not the fault of any one connected with e Council or headquarters that the reports and papers re not available in time for a studied examination by embers of their contents well before the meeting. evertheless, it is a pity; and this may detract somewhat om the value of the discussions. But the programme is substantial one; and therefore, although there are to be o afternoon sittings, it will be an advantage if speakers frain from being discursive and avoid generalities. ie maximum result from the time at disposal is what is quired.

As this issue of the "JOURNAL" is being prepared for ess, considerable interest is being recorded in the Great all at the Institution of Civil Engineers. There has been e welcome to distinguished visitors, and to delegates om overseas. There have been the presentation of edals and diplomas for valuable work and successful ort. A sum of £100, we are pleased to note, has been ted by the Institution as a donation to the Lord Moulton emorial Fund; and worthy additions have been made the list of distinguished men who are honorary mem- rs of the Institution. We have had the address of the esident (Mr. J. Ferguson Bell, M.Inst.C.E.), who has orked with characteristic energy to leave nothing undone hich could be done to make the meeting of 1925 perfect every detail. As we close our preparations for this ue, the reports of the various Committees are being ten in hand.

There is a point concerning the visit to Derby. One the items in the programme for the day's arrangements s tea at Haddon Hall—the famous seat of the Duke of tland. Our readers will have read with regret of the structive fire in the tea rooms at the Hall. The Presi- nt tells us this will need a modification in the plans, t only a slight one; and on the occasion each visitor ll receive a printed slip giving full particulars of the cessary change.

A complete report of the proceedings at the meetings, gether with descriptive accounts of the visits and the ctions, will appear in the next issue of the "JOURNAL."

Mr. Banbury Ball and Compulsory Electricity Patronage.

It is not every man who is in the position, or would have the courage, to take, in similar circumstances, such a step as has Mr. T. Banbury Ball, the much-respected Engineer and Manager of the Rochdale Corporation Gas-Works. Some electrical people will say he has resigned his office in a fit of pique; those of us who know him intimately, and have great regard for the fine conscientiousness which animates him in all things, will know full well that, when he says the course he has taken is a protest against an ill-advised piece of policy on the part of the Corporation Gas and Electricity Committee, this is the whole truth of the matter. He has given to the Corporation forty-four years' distinguished and loyal service; the act of the Committee which has led to the relinquishing of office, as from August 4 next (which will be the anniversary of the commencement of the long service), shows that such fealty does not count for much with the Committee. The resignation is due to their decision—come to behind Mr. Ball's back, and without any consultation whatever with him—to provide only electricity (instead of the dual services) in sixty-six Corporation houses which are being erected on the Kilworth Street site. While courtesy alone to their old adviser and official should have prevented this secret proceeding, the fact itself suggests that the Committee deliberately wished to take the course they did without his knowledge. The proceeding is so unusual, so out of harmony with considerate and circumspect administration, that the strongest possible protest against it is justifiable. In his letter of resignation (quoted in a later column), Mr. Ball states that no intimation was given to him that the question was under consideration; that he had therefore no opportunity of expressing his views on the matter; and that he is firmly of opinion the tenants of the houses should be free to exercise their own views on the subject. With Mr. Ball's action, there will be both sympathy and endorsement throughout the gas industry.

The incident raises the general question of policy in this matter. Where a Corporation owns, as representatives of the ratepayers, both the gas and electricity undertakings, the ratepayers do not expect that their representatives shall despotically decide for them which form of lighting, heating, and cooking they shall patronize. Things are coming to a pretty pass when, as at Rochdale, these things happen. It is bad enough when a municipality owns an electricity undertaking, and private enterprise has been supplying a town with gas perhaps for the best part of a century, for the Corporation to insist (when they ignorantly think they have the power) upon curtailing the liberties of the people by compelling them to give their custom—not on account of economic merit—to the municipal electricity concern. Even where ownership conditions of that kind exist, Parliament do not look with favour upon such assumption of autocratic power. Their preference is for "free trade" among competing local undertakings or businesses. We cannot

understand business men in any town tolerating the introduction into municipal policy of deprivation of anyone of freedom in the placing of custom. It is a bad principle; and the sooner it is ended the better. One thing it shows is that, having freedom, the major chance is that the tenant would give his preference to gas.

We have said that Parliament do not favour this new policy which has been invented through the possession of electricity trading powers. The tenant of any house within a certain distance of the gas-mains has the right under the general law, providing there is compliance with the prescribed conditions, to compel a gas undertaking to supply him or her. We have not heard of any power being vested in a municipal authority which abrogates that right of a tenant, and shackles him to a form of patronage which is detrimental to him. The Newport (Mon.) Corporation considered they had the power when in 1921 they compelled every tenant of the houses erected on the Somerton Estate to sign an agreement in which there was the condition that the tenant was not to use gas for lighting the premises. That is a case in which the gas supply is in the hands of a Company, and the electricity supply in those of the Corporation. In a Bill in Parliament this session (see *ante*, p. 444), the Corporation sought to obtain power, in connection with all lands and premises under their control, to place upon their use "such terms, conditions, and restrictions, as they may think fit." But a Committee of the House of Commons, in the interests of the freedom of the individual, added this provision: "The Corporation shall not make or impose under the powers of this section, any term, condition, or restriction with respect to the form of light, heat, and power, or energy to be used in any house, shop, office, warehouse, or other building, or on any lands, or with respect to the taking from any particular local authority, company, body, or person of any form of light, heat, power, or energy." The Rochdale Corporation and other local authorities who have any tender feelings for their electricity undertakings, and regard them as fit subjects for preferential treatment at the expense of individuals, should well consider this clause. Their policy which entails enforced patronage may lead to the whole question of the freedom of householders being raised in a very definite form, in view of the position of the general law regarding the right of tenants to demand a supply of gas, and the proper protection of the liberty of the individual against the prejudice engendered by municipal ownership of a trading concern.

Contrary Views.

In industrial polemics, the question at the moment of greatest interest to gas men is the one as to whether or not the competing electricity industry shall receive State aid and preferential treatment from the Government to assist its development. To the suggestion the gas industry is distinctly opposed on the grounds of its unfairness and unproved necessity; and it finds that a large number of long-sighted men in the electricity industry are of precisely similar opinion, and, in fact, hold views in the main according with those to which Mr. D. Milne Watson has given expression in two recent addresses. These, we are pleased to see, have arrested considerable attention, and have helped to promote thought on the subject, throughout the country. But naturally it was expected that there would be a fair amount of opinion in the electricity industry which would be diametrically opposed to that to which the President of both the Society of British Gas Industries and the National Gas Council gave utterance. The anticipation is fulfilled. We notice in one or two electrical papers that there are those in the electrical industry who (if their own industry were not concerned) would declare abhorrence of the principle of State aid to any one industry, but who are to-day searching carefully for excuses for accepting eleemosynary assistance from the State. These people, unlike others in their own industrial world, have no scruples in the matter; and they cannot bring themselves to the acceptance of the idea of rejecting (if offered) benefactions drawn from the pockets of taxpayers, even such large taxpayers as the rivals of electricity in business—the gas undertakings. But, apart from the iniquity of the proceeding—proposed, if not consummated—of the State giving assistance to a well-established and prosperous industry, these same electrical people appear to be so mentally dazzled by the suggested gift that they do not see that it must be accompanied by increased State interference, and, furthermore, that the Labour-Socialists are regarding the condition of State aid as the provision of a further stepping-stone to nationalization. These things are recognized by some wise electrical people, who are strongly hostile to such political schemes, and are ashamed that there should be in the electrical industry men who are willing to sacrifice its independence, and to try to extend its fortunes on political misconceptions and impracticable visions. They know them to be so, and are aware there is little benefit in them for the nation.

As an instance, there is the "Electrician," which, without controverting any of the definite statements and data of Mr. Milne Watson, indulges in a little veiled sarcasm; but it fails to advance anything material to show that his contentions and facts are baseless. As an example, it was pointed out in the addresses that cheap electrical power on the North-East Coast had not helped unemployment in the shipbuilding industry, and that in most industries the cost of power represents only a small proportion of the total works costs. This is how the "Electrician" attempts to counter the fair and sound submission of Mr. Milne Watson: "Electrical development will mean an increased demand for equipment of all kinds, and more raw material and more labour, which will relieve unemployment; and it will enable factories to be started without great capital expenditure, and so cheapen production, and again relieve unemployment." From what has been written in electrical quarters elsewhere, this particular prophet will not in this matter find universal honour in his own country. In the first place, what is meant by "electrical development?" What the politicians have in view is the development on a large scale of the sources of generation and the means of transmission; the idea being that this will cheapen electrical energy at the consumers' terminals. It is no use entering upon development of this sort without a demand can be created. Too much surplus plant and idle capital would be a heavy burden on the industry, and that would not cheapen electrical energy. Also, from the investigations which have been made, it is plain that the concentration of the generation of energy would only affect fuel costs, and any economy in those costs, the sagacious ones tell us, would be swallowed up in increased transmission expenses and losses. That is not the road to the development of electrical demand. The "Electrical Review," on the other hand, cautions its readers against undue optimism with regard to the cheapening of electricity supply as the result of changes in power station practice. Those in the electrical industry who are grasping for Government aid—financial and otherwise—should be sure of their ground before committing themselves. The writer in the "Electrician" further says that "the electrical industry is content to stand or fall on its merits." That is all we want; it is exactly that for which Mr. Milne Watson, in the name of the gas industry, is contending. It is only asked that the gas industry shall be kept free from State-aided competition—that the electricity industry should be "content to stand or fall on its merits." It is well that the gas industry should make this point clearly and forcibly before the Government positively determines to take the objectionable course; we hope the determination will be in the opposite direction.

We get much the same sort of criticism in "Electrical Industries." The editorial writer in this contemporary finds Mr. Milne Watson's comments "amusing." He does not cite the points that are so; and he deliberately descends to saying what is untrue when he asserts that the address to the Society of British Gas Industries "was one long protest against the popularity of electricity." It was nothing of the kind—not even inferentially. How it could be, we do not know, seeing that, a line or two further down in the comment, it is remarked that "Mr. Watson and other speakers *concentrated* upon the evil designs of the Government in 'bolstering-up' electricity." Our contemporaries who take the opposite view to the gas industry and to many competent electrical men appear to be unable to apply either logic or connected argument to the subject. The same paper says that it does not seem that the electrical industry needs "bolstering-up;" but "that it should be supported as a general benefit to the country, we cannot find it in us to condemn as iniquitous." There is plenty of evidence that the industry does not need "bolstering-up."

The several large generating stations that have been recently inaugurated, as well as the fat, unregulated dividends paid by many electricity concerns, prove this. It is difficult—indeed, impossible—to understand what possesses politicians who think that it does. However, we cannot see any difference between being "bolstered-up" and being "supported" by the Government. The opinions even of electrical experts are not in unison as to either the "bolstering-up" or the "support" of the Government being "a general benefit to the country." The iniquity lies in the proposal (if carried out) to give preferential State aid to a sheltered industry, without any proved need or national advantage. On the other hand, we have "Chemistry and Industry" writing in well-reasoned manner against State aid for any established industry.

It is not electrical power that will disperse the cloud of industrial depression. There are other factors more deeply rooted and widespread which require to be dealt with by the Government in the general interests of industry; and success in dealing with them would affect all industries alike, and so contribute to a common movement towards greater prosperity and relief of unemployment. Here, however, we have politicians contemplating, and endeavouring to persist in, a course which competent intellects believe is likely to do more harm than good. It was high time that a serious protest was made; and we are glad to find electrical men joining in it, and not being deterred from doing so by the flounderings and platitudes of some of their fellows.

A Cabinet Electricity Committee Appointed.

AFTER the foregoing article had been written, information came to hand to the effect that a Cabinet Committee has been appointed, under the chairmanship of the Attorney-General (Sir Douglas Hogg), to examine and report upon the electricity scheme drawn up by Lord Weir, Lord Forres, and Sir Hardman Lever. This course has been taken because it is believed that the matter could have more detailed consideration by a Committee than by the Cabinet as a whole. Thus final determination of this highly technical problem is to be of a political order. Perhaps this cannot be avoided. However that may be, there appears to be a disposition to push forward legislation. A preliminary draft of a Bill is being prepared by the Ministry of Transport for consideration by the Cabinet Committee; the hope being that the measure may be introduced before the summer recess, and carried through during the autumn. On the scheme generally, the Parliamentary correspondent of the "Daily Telegraph" makes this statement: "It is expressly disclaimed that the Government's proposals are on the lines of nationalization, because, while the State *will assist* in the great national developments that are projected, private enterprise will continue to be entirely responsible for the generation of electricity." If this is a true reflection of what is proposed, it indicates an intention of the Government to "assist" financially in the work of reorganization. One object is stated to be the gradual standardization of output, so as to facilitate the progress of linking-up the various generating stations. It is further presaged that the country is to be divided into areas, with provision for regional grouping of the electricity undertakings. By such means as these, together with the closing-down of the smaller stations, supplying the districts from super-stations, and carrying distributing systems into virgin areas, it is thought that it will be possible to ensure "cheaper power for industries, as well as cheaper current for domestic purposes." There opinions differ. If these indications prove correct, they will show that there are leakages somewhere, though the Weir report is supposed to be safely guarded until a scheme is finally adopted by the Government.

Coke and Sulphate in the Showrooms.

Is sufficient use made of our showrooms? That is a question that was asked in a paper read by Mr. H. D. Madden, of Cardiff, before the Wales and Monmouthshire Institution of Gas Engineers, as reported in this issue. We live and learn. The development of showrooms is the subject of evolution, the same as is that of most other things. In their case, the best development is made by the studied consideration of the purposes to which they are, or should be, devoted, and in most cases, the application of thought and inventive faculty will suggest means whereby they can be put to maximum profitable use. Mr. Madden's paper indicates various ways in which this can be done.

One part of the contribution we should like particularly to emphasize. There is a disposition in practice rigidly to follow the title of "gas showroom," and to utilize them only for demonstrating the merits of the various applications of gas. That is a limitation which amounts to short-sightedness. The gas showroom and its work, as well as the undertaking owning it and the consumers of gas, require the primary commodity to be at as low a price as circumstances will permit. We are passing through a period when secondary products are not yielding all we should like them to do for contributing to a low net cost per therm into the holder. To this end Mr. Madden's advice is to make use of the showrooms to give—particularly to coke and sulphate of ammonia—the largest possible publicity. But it must be publicity with the "goods" exhibited in a proper way, and suitably prepared for different services. As we travel about and make inquiry into this matter, it is found that in some areas anything that can be classified as coke is considered good enough for the market, and the indifference to cleaning and grading is something that is really calamitous to the building-up of a good trade in the commodity. We have no doubt it is the same in many parts of Wales as we have found it in several quarters in England. What Mr. Madden therefore recommends is that coke shall be given both the attention it deserves and the publicity it warrants; for, when properly prepared, it is an ideal smokeless fuel. He urges that the best coke possible should be manufactured by the use of selected and blended coals. In this connection, it is not always wise to give preference to the cheapest available coal; it is the ultimate cost of gas into the holder that matters, and in that coke plays an important part. Given good clean coke in graded sizes for all applications, prominent publicity in the showrooms, with appropriate literature at hand, and this fuel will begin to create a new demand for itself. Stress is also laid on the point that the showroom staffs must be in possession of correct knowledge regarding the suitability and uses of the different graded sizes, and be able to advise consumers and inquirers. Cardiff has found excellent benefit from these practices.

We congratulate the Company, too, upon what has been done in stimulating the sale of sulphate of ammonia in small quantities by giving prominence to it and its virtues in the showrooms. Only recently they commenced to offer neutral dry sulphate in 7-lb. linen bags, with instructions for use printed on the back. The product was shown and advertised in all the showrooms; and in a few weeks, more than 1500 individual sales were made. There have been heavy local purchases; and the radius from which inquiries now come has enlarged—due entirely to publicity, in which the showrooms take a part which cannot be over-rated.

More on these subjects will be learned from the paper. The Cardiff experiences authorize Mr. Madden to advise emphatically: "Never cease to hammer in the facts—Tell the world."

Gas Workers' Wages.

To-morrow is the day fixed for a further meeting of the National Joint Industrial Council for the Gas Industry to discuss the wages question. The position in which the matter was left on April 28 last was an agreement that no action on either side should be taken until the end of June.

Mr. Dunn's Thirtieth Annual.

Looking up a matter in the "JOURNAL" volume for 1896, it was noticed that the Annual Meeting of the Institution of Gas Engineers that year was the first at which Mr. Walter T. Dunn was present as Secretary. The one this week is therefore his thirtieth; and it promises to rank in interest with the best of those that have been held during the three decades. Hearty congratulations to Mr. Dunn, who, as the permanent official of the Institution, has done so much to help to mould its history.

Nearing the Date.

Papers for the Coke Competition must be delivered to the Editor of the "JOURNAL" on or before June 30. The conditions set forth in the "JOURNAL" for Feb. 18 must be observed.

Wembley.

The beautiful weather last week showed what a potent influence sunshine has upon the attendance at the British Empire Exhibition. The number of visitors on Bank Holiday alone was close upon a quarter of a million, and that was not by any means one of the most charming days of the week. The Gas Exhibit is securing, as it deserves, a large measure of attention; and, consequently, there is great satisfaction on the part of all who have had a share in its organization. Another feature has been introduced near the Exhibit. The enterprise of the Gas Light and Coke Company has brought into being a coke demonstration, regarding which particulars are given on a later page. At the sign of the "Jolly Jack Tar," the use of tar for road purposes is also being illustrated; and everybody is speaking of the attractiveness of this, as they are doing of the Gas Exhibit. The gas industry has made wonderful progress in the art of demonstration during the past few years; and for this there are men to whom we owe a large debt of gratitude.

Why that Big Span?

The question has been asked by many people why such a large span as 280 ft. is required for one of the sections of the temporary Waterloo Bridge. The secret has been divulged. It is that the Port of London Authority desired the London County Council to make it of those dimensions, in order to avoid the appearance of a "tunnel approach" at a portion of the river where it makes a bend, and where it is necessary there should be ample room for the navigation of steamers of 2000 tons, carrying coal to the Wandsworth Gas-Works. The growth of the gas industry has an influence even on bridge-building.

Mains of Insufficient Capacity.

In a note last week (p. 650), and in our "Parliamentary Intelligence," reference was made to the new mains-of-insufficient-capacity clause which has been agreed with the railway companies, and which will now be the one to be adopted in gas Bills and Orders. It has since struck us that, in the satisfaction of having this troublesome matter settled, no mention was made of the part taken in it by the little Pinner Gas Company, who valiantly, at their own cost, "stood-up" to the railway companies, and paved the way to the negotiations which have ended in the agreed clause [*ante*, p. 677]. The story of the part taken by the Pinner Company will be found in the issue of the "JOURNAL" for Aug. 6 last [p. 524]. In the negotiations which followed, the National Gas Council looked after the interests of the industry.

The Proposed Labour Alliance.

The great labour alliance which the extremest section of the Executive of the Miners' Federation desires to bring about is not going to be effected with a rush—if at all. There was a conference last Thursday between the representatives of the unions concerned. It was a big affair—105 delegates being present, representing 2,500,000 workers. The discussion is said to have been "animated," and to have continued for some two-and-a-half hours. The prime mover is Mr. A. J. Cook, whose aggressive and militant speeches about the country have not been to the liking of those trade union leaders who believe in operating in a constitutional manner. It is stated that there were clear signs at the conference that the miners' group had expected a more prompt response to their plans. But the feeling was that more information was required; while other unions were not going to be hustled into anything which might commit them to strikes to force demands of other unions, which might be hostile to the interests of their own members. For example, the miners' leaders at the present time are seeking a new wages agreement, and certain of them are anxious that the men should get more money with no obligation as to more production. This would mean increased cost of coal and a still lower demand from overseas; and such conditions would be injurious to employment in the very industries with the unions of which the miners are seeking alliance. From within the mining industry, evidence has come that the men can earn more money by increasing the production per shift. At the time of the last Trade Union Congress, the Miners' Federation had a membership of 750,000; the National Union of Railwaymen, 325,000; the Associated Society of Locomotive Engineers and Firemen, 59,000; the Transport and General Workers' Union, 295,000; and the Amalgamated Engineering Union, 245,000. These are among the Unions represented at the conference last Thursday. The desire for further information was general; and for this purpose it was decided to appoint a Committee. The resolution passed was as follows: "That in the opinion of this conference—having regard to the present industrial situation and the community of interests that must necessarily prevail among the organized workers—the furtherance of this movement could be best served by the appointment of a Committee to consider the suggestions submitted to the conference, and that each group of industries appoint two representatives to serve on that Committee, their names to be forwarded to Mr. Cook."

Nationalization of the Mines.

The Executive of the Miners' Federation have again been discussing the question of the nationalization of the mines, and have selected nine of their members to join a Committee of Inquiry, comprising three representatives from the Trade Union Congress, three from the Parliamentary Labour Party, and three from the National Labour Party. This Committee are to discuss the question of drafting a Nationalization Bill, which is to be regarded as the policy and programme of the Labour and Trade Union Movement. The Bill is to be the joint product of the miners and trade unions, and it will go a step farther than the miners' own Bill which not long ago was rejected by Parliament. The same fate will no doubt await the new Bill; but it will be of interest as mirroring the plans of Labour should ever they get a working majority in the House. A circular inquiry in the mining districts, it is stated, has resulted in a majority decision against any payment being made for minerals and royalties.

PERSONAL.

On Wednesday, June 3, at All Saint's Church, Rochester, was solemnized the marriage of Mr. LESLIE W. DUNN (elder son of the Secretary of the Institution of Gas Engineers) with Miss Sybil Beaney, elder daughter of Mr. R. J. Beaney, of Rochester. Hearty congratulations and good wishes to the happy couple.

In the pass list of the April examination for associate membership of the Institution of Civil Engineers appeared the name of Mr. W. J. COLLINS GARRARD, Second Assistant to Mr. Frank Prentice at the Ipswich Gas-Works. Mr. Garrard, who is the son of Mr. James S. Garrard, Secretary to the Eastbourne Gas Company, has now passed the whole of the examination.

RESIGNATION OF MR. T. BANBURY BALL.

An extraordinary position has arisen at Rochdale, following upon a recommendation of the Gas and Electricity Committee that electricity only shall be supplied to 66 Corporation houses that are to be built. As a protest against this policy, which he considers seriously injures the prospects of gas in other directions, Mr. T. Banbury Ball, who has for close upon 44 years been Manager of the Gas-Works, has resigned this office; and his resignation has been accepted with great regret—the Gas and Electricity Committee expressing their warm appreciation of the services he has rendered to the Corporation over this long period. Mr. Ball's views on the subject were clearly expressed in his letter of resignation, which was in the following terms:

> The Gas and Electricity Committee having decided to exclude gas from the 66 houses recently contracted for on the Cheltenham Street housing site, thereby seriously injuring the prospects of gas in other directions, I feel that I cannot continue to hold any longer the office which I have had the honour of filling nearly 44 years, and therefore beg to tender my resignation.
>
> No intimation was given me that the question was under consideration, so I have had no opportunity of expressing my views on the matter; but I am firmly of opinion that the tenants who are compelled by circumstances to occupy these houses should be free to exercise their own views as to what system of lighting, heating, or cooking they prefer.
>
> You will realize, I am sure, that I am taking this step with infinite regret; but I look upon the decision of the Committee in the matter as so serious that I have no other alternative.

It is understood that every effort was made by the Gas-Works Sub-Committee to induce Mr. Ball to reconsider his

decision; but he felt that he could not conscientiously do so in face of a policy which he regarded as inimical to the interests of the department for which he is responsible. The resignation then, as already stated, was regretfully accepted at a special meeting of the full Committee. At the conclusion of the meeting, the Chairman (Alderman Blomley) personally conveyed to Mr. Ball an expression of the high regard in which he is held by the Committee, and their great regret that they had no option but to accept his resignation most reluctantly. General regret at the necessity for so drastic a step on the part of Mr. Ball is felt in the town, where he is greatly esteemed for his courtesy and high integrity of character.

Mr. Ball has spent the whole of his working life in the gas industry; his first appointment having been at Jersey. In 1875 he transferred his services to the Leeds Corporation; and in August, 1881, he went to Rochdale. He is now 74 years of age. Practically the whole of the existing gas-works plant at Rochdale has been installed or re-modelled under his management.

The matter was debated by the Town Council last Thursday; and a report of the meeting is included in our news columns to-day.

OBITUARY.

ROBERT HALL BEST.

It is with regret that we record the death, which occurred on Monday, June 1, at his residence, No. 146, Hamstead Road,

The Late Mr. R. H. Best.

Handsworth, Birmingham, of Mr. Robert Hall Best, of Messrs. Best & Lloyd, Ltd., gas and electric light fittings manufacturers.

Mr. Best was born in 1843, and succeeded early to an important position in the firm with which he had been connected ever since—as part proprietor till 1878, then sole proprietor, and since 1879 as Chairman of Directors. It was his father, Mr. Robert Best, who founded the business. Although never a prominent public man (in spite of the many efforts to induce him to become a candidate for municipal and other honours), the deceased's social, educational, and philanthropic activities in Birmingham were many, and his influence in matters relating to art and industry in the brass trade went far beyond a local application.

Particularly was this the case with the results of his investigations into the economic conditions of the brass trade in Germany. Largely at his instigation, the self-constituted Commission consisting of Mr. W. J. Davis (then Secretary of the Brassworkers' Society), the late Mr. C. Berks, and himself, went over to Berlin on a tour of inquiry and research. The resultant report had a wide circulation, and stirred public opinion greatly. Long years of travel on the Continent, and his intimate touch with German manufacturers, convinced him that the Germans were not in the very retrograde state of civilization and development nearly everyone then thought; and Mr. Best was largely instrumental in inculcating a more general realization of the fast-growing efficiency in their manufactures, of their formidable business organization, and of their thoroughness in matters educational and scientific. He thus drew attention to the growing menace to our trade which Germany represented, and the need for rousing ourselves from lethargy in methods of education, as well as in the production and marketing of commodities, if we were to hold our own.

His next great work was propaganda for secondary education and trade schools. Here, again, he went to our trade rivals in Europe for example and precedent, spending a great deal of time in thorough investigation of these institutions in Germany—particularly in Munich. He brought his research to a head in a book he wrote in collaboration with Mr. C. K. Ogden, B.A., of Magdalene College, Cambridge, entitled "The Problem of the Continuation School." His main aim was to avoid the loss of training occasioned by so large a proportion of boys drifting into blind-alley occupations, and to replace it with wise education on broad lines; using trade classes as a focus of interest and a starting-point. It was not by any means purely vocational training he was after; the duties entailed by citizenship and the wide diffusion of simple economics and history, were, he thought, far more necessary for the training of an alert and efficient industrial people. He supplemented his writings on this subject by a great deal of lecturing; and his efforts only just missed bearing practical fruit in the brass trade. A school was about to be started in Birmingham, along the lines recommended by him, when the war broke out, and set-back the clock of progress in so many directions.

Another much needed reform for which he laboured was the application of art training to industrial needs. He was profoundly disappointed and discontented with the activities of art schools in the direction of improving design in industry, and worked hard for the linking-up of the art teaching in Birmingham with the manufacturing needs of the city.

His work as a town councillor for Handsworth was brief, and occasioned only by a disagreement of a section of the inhabitants of Handsworth with the proposal to include that suburb in the city's boundaries. He was strongly in favour of the greater Birmingham scheme, which came to fruition in 1911, and defeated his opponent at the Council election which was fought on that issue.

For many years Mr. Best had been President of the Brassfounders' Employers' Association, in which position his activities were highly appreciated by employers and employees alike. He was a man of wide sympathies, and of great knowledge.

His wife predeceased him in 1921, and his second son, Frank Behrens Best, was shot-down while flying over the enemy lines in 1917. He leaves one son—Mr. Robert Dudley Best.

We regret to hear of the death, at the advanced age of 91 years, of Mr. WILLIAM GARTON, formerly Accountant to the Nottingham Corporation. Although identified with the Nottingham gas undertaking for the long period of 63 years, he had, previous to that association, been in the service of Mr. William Hunt, Solicitor, of Nottingham, Clerk to the old Company. Upon the retirement of Mr. Garton five years ago, he was appointed Consulting Gas Accountant. Extremely conscientious in his duties, he was a man of great integrity, and a highly respected official of the Corporation.

The death occurred, suddenly, on the 3rd inst., of Mr. E. F. SPURRELL, Borough Engineer of Holborn. To Mr. Spurrell the newly-formed Institution of Public Lighting Engineers owed its inception; for it was he who, in the autumn of 1923, seeing the need of such an organization, called together those he thought might be interested. When the Institution was launched, he became a member of the Council, which position he held at the time of his death.

FORTHCOMING ENGAGEMENTS.

[*Secretaries of Gas and Kindred Organizations are asked to assist in making this diary of events as complete and useful as possible by sending the earliest intimation of all meetings.*]

June 12.—INSTITUTION OF GAS ENGINEERS.—Visit to Derby. Members should note that the luncheon will be in the Drill Hall, Derby—*not* the Assembly Rooms, as indicated in the programme.

June 19.—INDUSTRIAL GAS SALESMEN'S CIRCLE.—Meeting at the Council House, Birmingham. Inspection will be made of the industrial gas demonstration rooms and research laboratories of the Birmingham Gas Department, and visits will be paid to the Windsor Street heat treatment shops, and to the works of the Moss Gear Company, Ltd.

June 20.—LONDON AND SOUTHERN DISTRICT JUNIOR GAS ASSOCIATION.—Visit to the Cambridge Gas-Works.

June 30.—LAST DAY FOR COKE COMPETITION PAPERS.

ELECTRICITY SUPPLY MEMORANDA.

IN the last issue of the "JOURNAL," there appeared a letter from Mr. J. Horace Bowden, the Electrical Engineer of Poplar, which dealt with our recent comments on the charge for electricity for heating water for the public baths at Poplar, and on the waste of coal which results from the use of an agent produced at such a low efficiency as is represented by (so it now transpires) 2½ lbs. of coal per KW.H. Assuming the coal has a heating value of 13,000 B.Th.U. per lb., the production of 3420 B.Th.U. per 32,500 B.Th.U. in the coal would be equal to 10·5 p.ct. efficiency. We should like to preface further remarks by saying that "impudent stunt" and "real live" Electrical Engineer of Poplar were quoted in our comments and were expressions published in electrical papers. Our readers will remember that an electrical paper made the claim that the heating by electricity of the water for the Poplar baths was cheaper than by gas, and that was why gas had been "thrown out." The comparison was made with gas at ordinary price and electricity at a charge representing average fuel costs or thereabouts—no other cost being included. No one can legitimately claim that this is an ordinary commercial transaction; but Mr. Bowden is not different from other electrical engineers in adopting extraordinary arguments for justifying what he is doing. We have not the slightest doubt that this public bath water-heating business is purely preferential because it is a municipal undertaking. The current being taken at off-peak periods, our correspondent calls the supply "a bye-product," and says it must be regarded as such. The suggestion is a remarkably subtle one; but we have a notion that the Poplar Borough Council Electricity Committee would be rather reluctant to supply electrical heat on the same terms during off-peak hours for other purposes. But why not, if it is such a good thing for the undertaking? We see that the electrical energy for the public bath water heating is supplied between the hours of 5 and 8 a.m. (which covers breakfast time), and between noon and 2 p.m. every day and after 1 p.m. on Saturdays. Those times would cover the dinner period for most people in Poplar. Then why not sell the "bye-product" for domestic cooking at average fuel costs? The bye-product argument can be beaten-out to diaphanous substance. Why, too, select fuel costs only for averaging-out in order to decide the charge for supplying heat to the water for the public baths? The trick of averaging the fuel costs over a large consumption basis, and the other costs over a small consumption basis, and making the latter pay all the "other costs" is not equity.

Poplar Bath Water.

Mr. Bowden claims that this sort of supply is a bye-product, and must be regarded as such; and he says that in the gas industry bye-products are worth exactly what they will fetch in the market. That is a perfectly philosophic and yet obvious statement. Applying it to the off-peak-load electrical "bye-product," it is clear that this will not fetch much per unit in the market, and the same applies to electric cooking and heating and much of the power business—not all off-peak loads. Mr. Bowden is ingenious; but he has overlooked the fact that there is no analogy between his bye-product and the bye-products of gas manufacture. Every one of our bye-products stands in a different class. They are not the same as Mr. Bowden's "bye-product," which is in every respect identical with his primary product; and the only excuse he can find for calling it a bye-product is in the incidence of its use in respect of time. In the case of our secondary products, every charge in their preparation for the market is accounted for in the price; and Mr. Bowden cannot show us any case in which the whole of these charges are not fully covered by the revenue, even in this time of poor markets. It is only because the profits are less from the secondary products that the aggregate sum to be deducted from the gross cost of coal leaves the net price of the latter at a figure which has compelled in some cases the raising of the price of gas. But we cannot detect any real profit in Mr. Bowden's electricity "bye-product;" and, anyway, the price charged shows that it is a "bye-product" of exremely low intrinsic value from the heating point of view. He would not charge that price if it could command a higher one. Gas undertakings are not so foolish as to sell gas at the "average net cost of coal." If they were, the Gas Company supplying in Poplar would have been able in 1924 to sell at about 2d. per therm—the net cost of coal having been 1·848d. per therm. To obtain the same potential thermal value from electricity rather more than 29 KW.H. would be required. Differential prices do obtain in the gas industry for different services; but not such differential ones as are the vogue in the electricity supply industry. It would, of course, be possible to sell gas at convenient times at a little over net cost into the holder; but then there would be distribution and other charges which would have to be borne by the consumers generally. Those charges exist in all manufacturing establishments, including electricity undertakings; and in many manufacturing works, including gas undertakings, there are times of the year when a large part of the plant is standing idle. Even in winter time there has to be a good margin of gas plant to meet the vacillations of the heating load, which are often of a somewhat violent order. There are not, therefore, such extraordinary differences in electricity supply and gas supply as Mr. Bowden pictures in, we think, shallow fashion for the purpose of justifying a charge for water heating at a little above the average cost of fuel—leaving the burden of other costs to be borne in other quarters. We are not shivering over his prospective raising of steam from the waste fuel of collieries. When he uses it in his boiler furnaces, he may find that it would be rather a good thing to employ a proportion of gas coke on (say) the Sandwich system, in order to get a porous, free-burning fuel bed.

The "Bye-Product."

Mr. Bowden's letter does not deal with the question of extravagant heat expenditure for raising the temperature of water by electrical energy, beyond the incidental remark as to the use under his steam-boilers of waste fuel from collieries. We had therefore hoped that, if Mr. L. Jefferson-Hope, the Chief Superintendent of the Poplar Borough Baths and Wash Houses Department, replied to our criticisms, he would have discussed this particular point, which is one of extreme importance in connection with the utilization of fuels for any purpose. He contributes a letter to this week's issue of the "JOURNAL;" but he entirely avoids making any point of our criticism regarding the larger tonnage of coal required to do a certain amount of work the electrical way than is needed by using the fuel directly under a steam-boiler. It is perfectly obvious this would be so when one considers the efficiency of a boiler; and then, using the steam for electricity generation, note how the efficiency tumbles down to an extremely low point—in the case of Poplar to about 10½ p.ct. of the original thermal value of the coal. Instead of dealing with this technical matter (which is to-day regarded as being of vast importance in connection with the conservation of coal and the co-ordination of the use of our fuel supplies), he tells the story of how the Gas Company supplying in the district missed this particular load. This is, of course, interesting up to a point; but it does not bear upon the general question of whether or not electricity, from either the thermal or cost points of view—if a fair commercial charge is made—is a rational method of providing heat for raising the temperature of water. In passing, it is observed that our correspondent states that coal-fired boiler plants are uneconomical for his particular purpose on account of the intermittent character of the business. However, we thank Mr. Jefferson-Hope for his work in favour of gas heating, though this did prove abortive; but really there is nothing in his communication which calls for a reply from us, as the policy of the Gas Company in respect of this particular load is not a matter which would lead to any profit by being discussed in our columns.

An Important Point Avoided.

On various occasions we have advocated that more information should be supplied to the daily and weekly newspapers as to the technical position and progress of the gas industry in the utilization of coal, as well as in the application of its products to domestic and industrial services. We suggest that there is a writer on the staff of the "Yorkshire Post" who requires a little light and leading on this subject, for he has given the best possible certificate to the need that anyone could possibly pen. An editorial article appeared in the "Post" on the subject of "The Government and Electricity." Mr. Arthur Bray wrote to the Editor protesting against the ignoring in the paper of the great advantages that gas has over electricity in lighting, heating, and cooking. He also criticized the suggestion that electricity should be subsidized at the expense of gas, and pointed out that the arguments in favour of subsidization could be applied equally to gas undertakings as to electricity supply ones. But he cannot see why either should be assisted; his preference rightly being that both should work in healthy competition. Among other points made by Mr. Bray was that, if all the houses in Leeds were equipped with gas appliances for heating, cooking, and hot water supply, four-fifths of the pollution to which the editorial writer referred would disappear, and the pockets of householders would on balance greatly benefit. In an editorial note appended to the letter, there is displayed a want of knowledge which is to be deplored in a paper of such influential standing as the "Yorkshire Post." Allusion is made to Mr. Bray's statement as to four-fifths of the pollution of the air being removed by the use of gas; the editorial note writer saying five-fifths would be removed by the universal use of electricity. Of course, Mr. Bray did not intend his "four-fifths" to be regarded as a definite proportion. He knows what apparently his critic does not, that in industrial work it is impossible to eliminate entirely the use of solid fuel; so that there could be no universal application of either gas or electricity for industrial heating. Electricity cannot do more than gas in purifying the atmosphere, and as a matter of fact it would be ruinous to individuals and disastrous to the country at large to attempt it.

Educate the Daily Newspapers.

An Unsupported Statement.

This brings us to the most important statement of the writer of the editorial note. He says: "Our leading article suggested that electricity which serves both the domestic and industrial purpose could, under a well-co-ordinated national scheme, be produced and distributed at a unit cost sufficiently low to help industry and ease the burden of the householder, whereas it is now impossible to co-ordinate coal and gas supplies." Our contemporary will excuse us pointing out that the statement is wholly senseless. We should like to know the grounds, supported by data, on which he bases the suggestion. There are physical obstacles in the way of electricity being produced at a unit cost sufficiently low to make its use universal for heating; and the waste of our coal resources would soon show itself in a manner so appalling that the writer in the "Post" would wonder why he had been led to entertain such fantasy as he declares possesses him at the present time. He considers, too, that gas is a form of power which is rapidly becoming obsolete. We should be most happy further to discuss this matter with the writer in our contemporary, if he will supply us with the grounds upon which he bases his dogmatic assertions. But we would suggest to him that in a technical discussion it is rather childish to write thus: "It must, in conclusion, be admitted that electricity will never be as efficient as gas at leaking from faulty lead piping to the benefit of the gas undertaking's receipts and the detriment of the unsuspecting ratepayer and his family."

WEMBLEY AND THE ARTS OF DISPLAY.

Sir Lawrence Weaver's Book.*

The British Empire Exhibition affords a unique opportunity for the study of a type of publicity which has for too long in this country been practised without being understood. Sir Lawrence Weaver, Director of United Kingdom Exhibits at Wembley, has published this spring a book which should prove of permanent value in preserving many of the lessons that Wembley is able to teach us. He sets out to consider solely the question of display, but without digressing from his argument he provides incidentally much information and criticism on many aspects of exhibition work; and his 366 beautifully reproduced illustrations serve admirably to drive home the points. To the gas industry, moreover, because the industry both was and is so well represented at Wembley, the book has a special interest.

Why is it fair to say that the arts of exhibiting are not understood? Because the object of an exhibition is so rarely grasped. Not only the man in the street, but the exhibitor himself is constantly heard to ask: "Does such-and-such an exhibition pay?"—meaning, of course, "Can you trace any definite results directly to it?" The question is proof at once of the failure to understand its object. For the object of exhibitions, as Sir Lawrence Weaver says, is "publicity, not sales;" in other words, they are, like other kinds of advertising, a casting of bread upon the waters. The exhibitor should aim not at meeting the immediate needs of those who visit his exhibits, but at leaving upon their minds an impression which will be remembered when at some future date a need is felt. The crowds, for example, who daily pass through the Wembley Gas Exhibit have not gone there to see if gas can solve this or that problem for them; they are for the most part casual wanderers "seeing what there is to see," pausing wherever something picturesque, or something wonderful in size, in colour, or in movement, may happen to arrest them.

This is the reason why, at an exhibition designed for the million, it is wrong to display all your wares or products in uninspiring rows, and why it is right to give some picture such as the Gas Exhibit Committee have evolved, which pleases and educates, but does not pretend to say: "Here in a nutshell is all that the gas industry can do."

Admit but this, and it follows at once that the success of an exhibit depends very largely on the "arts of display," in which, as Sir Lawrence Weaver says, "no artist is too good to be employed;" and the same will apply to the architect. Sir Lawrence Weaver illustrates this well from last year's Wembley Exhibition—and, much more easily, from the Munich and Gothenburg Exhibitions of 1922 and 1923; for in Germany the value of originality and art were recognized far better. The value of art can be illustrated again from an exhibit new to Wembley this summer—that delightful and arresting scene of the road beside "The Jolly Tar," which winds away upon the backcloth into the hills painted by Norman Wilkinson, and is perhaps the most effective exhibit of its size in the whole Palace of Industry.† And the Gas Exhibit itself, last year's display—and how much better this year's!—is cited by Sir Lawrence Weaver as one of the best examples in the whole Exhibition.

To us his comments have a special interest. With obvious sincerity he points out that "the success of an industry's display will normally depend upon the more or less complete community of interest between the participating exhibitors. The ideal is achieved when the participants are prepared wholly to sink their individuality, and to concern themselves only with the ideal presentment of the scope and possibilities of their industry"—when, that is to say, they recognize that their object is "publicity not sales." The ideal is, however, in the author's view, not readily achieved "save in the case of a widespread public service such as the gas industry;" the fact, of course, being that the gas industry has to an unparalleled extent established, not merely for exhibition purposes, but for all its activities, a system of genuine co-operation which has the right spirit behind it. The result, to quote Sir Lawrence Weaver, is that "the whole Exhibit was organized in the interest of all gas undertakings, whether owned by companies or municipalities, including many outside the United Kingdom"—and, he might have added, equally in the interest of all the appliance manufacturers. "Its anonymity," he continues, "added to the conviction of efficiency and service which was impressed upon the minds of visitors, due in no small measure to the skill with which Mr. Austen Hall, the Architect to the Committee, had planned and decorated a charming co-ordinated display."

Such is Sir Lawrence Weaver's praise for the Exhibit of last year. He would be bound to speak even more highly of "the second edition." For in his concluding chapter on "Exhibitions of the Future," he has made an appeal not only for that "harmony of display," that co-ordination which was already a striking feature of the Gas Exhibit, but also for better lighting, better velaria, more invention in colour schemes, and, above all, more movement. In every one of these respects the Gas Exhibit, 1925, has gone one better than its predecessor—and the Exhibit of last year was good enough to be deemed worthy of nineteen pictures in the book, one of them a whole page in colour, showing the spacious and artistic Rest Lounge.

We said that Sir Lawrence Weaver was not guilty of digression. We admit an exception, but forgive it. He has a chapter on the Exhibition posters; and in that chapter one concluding paragraph which deals with the posters used by individual exhibitors. It is worth quoting in full:

> "And when the posters issued by the Exhibition authorities themselves are detailed, the story is by no means told. Many fine posters were used by exhibitors themselves to advertise their wares or to call attention to their display in the Exhibition. For the most part, and naturally, letterpress posters best served their purpose, but in one case they indulged, with particularly happy effect, in the work of a very able poster artist. I refer, of course, to the very striking poster by Mr. Septimus Scott, issued by the British Commercial Gas Association, and entitled 'The Spirit of Coal.' Starting as a sixteen sheet, it proved to be easily the most ubiquitous of the Exhibition posters. It rose flaming from the hoardings. It looked down from the sides of houses. As a double-crown it found its way into the railway stations, and in still smaller form it adorned the advertisement pages of newspapers and magazines."

High praise. But was it not deserved?

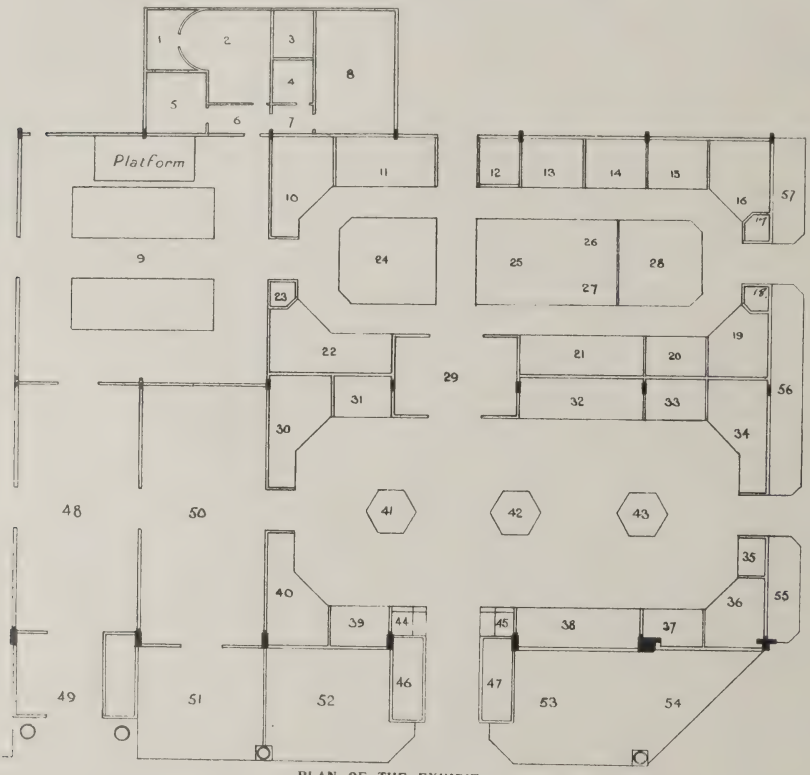
Card Printing Cheapened by Gas.

Many people, says "Industrial Gas," met for the first time last Christmas the engraved process cards and announcements; and they wondered how it was possible to produce such cards so cheaply. This engraved process printing consists of printing with an ordinary press; and this is followed by a heating operation. A slow-drying ink is used in the printing, and then the cards are dusted with a resin or shellac base powder. An automatic shaking operation removes all the powder except that which sticks to the wet ink. The cards are then heated in an oven, and the powder becomes merged into the ink. In this process a uniform heat zone of correct temperature is essential. Any variation in the heat zone temperature while the work is in progress will result in spoliage. Electricity was first used as a heating medium; but owing to the large percentage of blow-outs, the uneven work produced, and the high cost of operation, it was decided to employ gas. Using this fuel not only produced cards that were better than those resulting from electrical heat, but a great saving in operating costs was realized. With the gas-fired machine, it was possible to secure a far greater variation of heating than was possible before. Further, with electricity it was necessary to have twelve machines in working order all the time; whereas with gas only seven were required. A two months' comparison made in connection with a New York plant before and after the conversion to gas shows a really large saving made in fuel costs alone, to say nothing of greatly increased production, &c.

BRITISH EMPIRE GAS EXHIBIT.

READERS who are visiting London this week to attend the annual meeting of the Institution of Gas Engineers, are, of course, arranging to include in their programme at least one inspection of the British Empire Gas Exhibit, in the Palace of Industry at Wembley. With the main features of the remarkable display to be seen there, they will already have made themselves familiar, by the aid of the detailed description that was given in the "JOURNAL" for May 13, and the various photographs which have since appeared in our pages; and the addition of the accompanying plan of the exhibit, with the explanation of the figuring, will make it perfectly "plain sailing" for them.



PLAN OF THE EXHIBIT.

1, 2. Allocated to Society of Women Journalists.
3. Store.
4. Office.
5. Demonstrator's kitchen, with geyser and gas cooker.
6, 7. Lobbies.
8. Committee room.
9. Cookery demonstration hall, with selection of cookers and hot water appliances placed on stands around the walls. On the demonstration platform are two eye-level cookers.
10. Model domestic kitchen, fitted with cooker, combined coke and gas boiler, and other labour-saving devices—including a low-pressure gas iron.
11. Laundry, with a big high-pressure iron for the ironing of large articles, and other high-pressure and low-pressure irons; also drying cabinet, and two coppers for the boiling of the articles washed.
12. Illustration of shop-window lighting, showing sulphate of ammonia and various bye-products.
13. Greenhouse, fitted with outside gas water heater for providing the heat necessary for the cultivation of flowers.
14, 15. Views of a room under varied conditions. In the first case the room is heated by gas, with the result that one observes a general appearance of cleanliness—the window revealing a clear and sunny atmosphere. The second view is of the same room heated by a coal fire grate, with the result that the appearance of the room is dirty, owing to the smoke of the coal fire and the dust from the cleaning of the grate and removal of the ashes. From the window is seen a smoke-laden atmosphere.
16. A 20 B.H.P. gas engine used for driving a dynamo for generating electricity for the working of the ventilation fans, and running of motors for compressors, &c. The special feature of this stand is the raising of steam by utilizing the exhaust gases from the engine.
17, 18. Fan chambers.
19. Main meter house.
20. Chauffeur's kitchen, lighted by gas, with gas cooking stove, gas copper, and coke fire.
21. Garage, lighted by safety gas lamps and gas radiator. There is a work bench, with brazing hearth and gas-heated soldering iron.
22. Hotel kitchen, illustrating the application of gas to large cooking requirements.
23. Fan chamber.
24. Cinema lounge.
25. Converted coal fire stand, showing old-pattern coal fire grates adapted to the fitting of modern gas fires.
26. "Hobbies"—work bench provided with gas-heated soldering-iron stove and glue pot.
27. Jewellery stand, with small enamelling furnace.
28. Pottery stand, having a gas-fired pottery furnace.
29. Ante-room, with handsome gas fire.
30. Children's nursery, lighted and heated by gas.
31. Bathroom, demonstrating lighting and water heating by gas.
32. Log cabin, showing various articles in the manufacture of which gas or its products play an important part.
33. Fruit bottling—boiling of fruit by the aid of a gas cooker.
34. South Africa—interior of room heated and lighted by gas.
35. Larder, demonstrating the making of ice by gas.
36. India—bathroom lighted and hot water supplied by gas.
37. Verandah, showing coloured fabrics illustrating dyes obtained from tar.
38. New Zealand—interior of room lighted and heated by gas.
39. Kitchenette, showing modern kitchen lighting, heating, and hot water furnished by gas. Every convenience in a small space.
40. Canada—interior of lounge hall, lighted and heated by gas.
41, 42, 43. Pylons of fires of various finishes and designs.
44, 45. Inquiry counters.
46, 47. Stores.
48, 49. Empire food exhibit.
50, 51. Coke exhibit by the Gas Light and Coke Company.
52. Motor trades exhibit, showing various gas appliances used.
53, 54. Gas engines exhibit, showing 150 B.H.P. and 17-19 B.H.P. engines, and gas-heated wafer making machine.
55, 56, 57. Industrial gas exhibit, displaying various types of furnaces for case hardening, metal melting, sugar boiling, pottery work, &c.

Distinguished Visitors.

The Gas Exhibit has recently been honoured by the presence of some distinguished visitors. On Friday, May 28, their Royal Highnesses the Duke and Duchess of York spent a considerable time in this attractive portion of the Palace of Industry, and were greatly interested in the entire display made by the Gas Exhibit, which they regarded as an excellent one. They were particularly struck by the ice-making machine, which was in operation, demonstrating the making of ice by the application of gas. They also commented on the artistic display of lighting fittings, and the control switch, whereby gas is rendered as convenient as electricity.

This is what the "Daily Graphic" had to say on the subject: After lunching at the Garden Club, the Duke and Duchess of York spent the greater part of the afternoon going over the extensive Gas Exhibit in the Palace of Industry, where the Duchess was especially interested in the many domestic labour-saving appliances. In the Model Laundry a frock was being ironed by the giant "Gladiron," which weighs 90 lbs. The assistant had to explain to the Duchess every detail of its working by gas pressure operated by electric motor, the electricity for which is generated by gas. Another exhibit in which she was especially interested was the gas refrigerator. "Fancy making ice-cream by gas!" she exclaimed. "It does seem strange."

The Archbishop of Cape Town and Princess Beatrice visited the Exhibit on the following day, when the Archbishop said that the South African room was a very realistic representation. H.R.H. Princess Beatrice manifested a very lively interest in the display, and asked a number of questions which indicated her appreciation of domestic problems.

Other visitors have included Sheik Hamad bin Isa al Khalifah and his brother Sheik Abdulla, who, in their robes of black and gold and brown and red, with picturesque embroidery, proved keen inquirers after truth. Sheik Hamad placed an order for one of the ice-making machines just alluded to—explaining that he has recently started an ice-making factory in his dominions. A description of this novel little machine—the "Delaygue" refrigeration plant—was given in the "Journal" three weeks ago [see p. 523]; and the appliance will probably find a place in many showrooms, for ice making by gas as a feature could be safely trusted to arouse keen curiosity and to lead to business.

These distinguished visitors from near and far are an illustration of the very real interest that is being displayed in an exhibit which has had praise bestowed upon it from all quarters.

Gas in Jewellery Work.

The attention of those inspecting the Gas Exhibit may be drawn to a large glass case filled with handsome personal ornaments, into the fashioning of all of which gas has entered.

Our Photographs this Week.

We are able in this issue to add to our series of photographs.

BEDROOM-BOUDOIR IN THE NEW ZEALAND SECTION.

An Up-Country Store.

Gas Equipment for a Hotel Kitchen.

One would find it difficult to make a choice for tasteful arrangement from among the various Empire scenes; but in any such choice New Zealand would no doubt be in the front rank. It takes the form of a bedroom-boudoir, heated by a gas fire harmonizing with the period and decorations of the room, and lighted by gas brackets and table lamps. The next is a realistic reproduction of an up-country store, such as the pioneer depends upon in every Colony or Dominion. The contents of this store serve to illustrate the manifold resources and uses of gas in industry, as the whole of the stock consists of either bye-products of the gas industry—*i.e.*, disinfectants, drugs, fur preservatives, sheep-dip, &c.—or articles in the manufacture of which gas or one of the many bye-products of gas making is habitually used. The range of articles shown is enormous. Lastly there is portrayed modern gas equipment for a hotel kitchen—every item of which speaks for itself, and for efficiency, cleanliness, and the saving of labour.

Housing Section of the Gas Exhibit.

In the Palace of Housing, space is occupied by what is named the Housing Section of the British Empire Gas Exhibit. Here is to be seen an appropriate display of cookers, fires, hot water apparatus of all types, gas irons, boiling rings, grills, hotplates, &c.—in fact, everything in the shape of gas equipment that is suitable for use in the home. The nearness of this display to the model houses will no doubt make it of substantial value as a "business getter," though nothing of an elaborate nature has been attempted here. The attention of the public is drawn to the fact that it is a supplementary stand, and they are invited to visit the main Gas Exhibit in the Palace of Industry. Two large boards tell the stories of (1) gas in the domestic field and (2) gas in the industrial field.

THE WEMBLEY COKE EXHIBIT.

Gas Light and Coke Company's Successful Demonstration.

Propaganda work of first-rate importance is represented by the excellent Coke Exhibit which has been undertaken by the Gas Light and Coke Company in a compact space adjoining (and communicating with) the British Empire Gas Exhibit. At first blush it might appear difficult to make anything with a "draw" in it out of a coke exhibit. Not at all. There is to

be seen here—on the very threshold of the exhibit—a device which will ensure for the display a steady stream of popularity. It was, indeed, a happy inspiration to fit up in this commanding position—outside the exhibit proper, and in the main gangway leading to the conference halls—a hot water fountain, giving a plentiful supply at 180° Fahr.; the end being thus successfully achieved of definitely associating coke with hot water. The hot water for this fountain is supplied by coke boilers in operation within the exhibit; and it makes an irresistible appeal to curiosity.

This curiosity once aroused, interest must inevitably grow; and the inquirer will enter what most nearly represents, perhaps, the big reception hall of a mansion. The exhibit has been designed by, and constructed under the instructions of, Mr. Walter Tapper, F.R.I.B.A., of No. 10, Melina Place, London, N.W.; and he has produced a delightful result within the small space at his disposal. In fact, one can fairly bestow upon it the highest praise, and say that it is fully worthy of the Gas Light and Coke Company, from whatever aspect it is viewed. It demonstrates effectively one basic fact to all and sundry—that there is no need to wait for a smokeless fuel; for such a fuel is already here, available for every purpose for which fuel is required.

Fires and Boilers.

Three open coke fires will be found of special interest. The first shows an ordinary well grate, adapted on the principle advocated by Prof. C. V. Boys, F.R.S.—that is to say, all access to the underside of the fire is cut off. The fire burns on a blank firebrick hearth, demonstrating the fact that, instead of a strong draught being necessary, a coke fire burns brilliantly with a minimum amount of draught. Next there is an Eagle Range Company's hearth grate, which also has a firebrick bottom, but provision is made for the removal of fine ash into an ash-pan below. The third open fire is a "Florence" grate

made by the London Warming Company, which is provided with a back boiler, giving a plentiful supply of hot water.

Other exhibits include a model artizan's kitchen equipped with a "Sentry Minor" coke boiler and a gas cooker; while a radiator is connected-up, to demonstrate that an adjoining room can be heated from the same coke boiler. Another model kitchen is provided with a "Koke" boiler. This is a steel boiler, made by Messrs. Balmforth, of Luton. It has a long life, and is not liable to crack, though such failures among the cast-iron boilers so far are unknown. A model bathroom contains a wash-basin, towel rail, and magnificent bath.

Finally there is a selection of coke fired boilers which have been tested and proved by the London Coke Committee.

The Industrial Side.

In the industrial exhibit outlets for coke as a fuel are demonstrated mainly on the "Sandwich" system. There is a large-scale model of a modern water tube boiler, as used by the London County Council, and at other power stations, fitted with mechanical stokers adapted for coke and coal firing on this patent "Sandwich" system.

It may be recalled that the London County Council have recently purchased 45,000 tons of coke for use on this system. Deliveries of coke are to be made at the rate per week of about 1400 tons, equivalent to some 50 p.ct. of the total fuel consumption of the power station. The need for economy in operating the London County Council tramways is only too well known; and it is gratifying to note that, as a means to this economy, coke has been adopted for use in preference to crude coal.

Incidentally, this use of coke at important power stations—which include those of Marylebone and the London Electric Supply Corporation—illustrates a form of co-operation between the electricity supply and gas supply industries which is not only practicable but economical, as well as being in the national interest.

ROAD TAR AT WEMBLEY.

At the Sign of "The Jolly Tar."

Mention is made of the visit recently to the British Empire Gas Exhibit of Her Royal Highness Princess Beatrice and party; and also Sheik Hamad, with his brother Sheik Abdulla. On the same occasion both parties inspected the British Road Tar Exhibit of the National Gas Council in the Chemical Section of the Palace of Industry, and expressed keen pleasure at seeing so attractive a display. Her Royal Highness's exact words were "a very charming and useful exhibit."

Quite a lot of inquiries are being received at the stand; and they are not only from home sources. The President of one of the largest Paving Companies of America admitted the pleasure the exhibit had given him, and his appreciation of the information he had derived from it. An interesting feature is the number of what may be termed domestic inquiries—*i.e.*, in connection with garages, garden paths, &c.

TARRED ROADS AND FISH LIFE.

In another part of the Chemical Section of the Palace of Industry is a very ingenious working model which is attracting a deal of attention, and is understood to be exhibited by the South Metropolitan Gas Company. Water to imitate rain is continually running straight off three separate sections of tarred road into a pond in which numerous fish are swimming about.

The model is in the interests of "specially refined road tar, non-toxic for fish and plant life." It is pointed out that the "two periods when surface drainings from a road treated with ordinary tar are considered toxic to fish life are: (*a*) Immediately following the application of tar; and (*b*) when disintegration of the road surface occurs." In order to reproduce these conditions, one section of the roadway in the exhibit is retreated periodically; the remaining sections being allowed to age normally.

GAS SUPPLIES AT WEMBLEY.

The use of gas at the Wembley Exhibition is still extending. We learn from the Brentford Gas Company that a large number of additional supplies have been put in.

The Chiswick Boot Polish Company are using gas for the necessary operations of melting and filling the tins with their "Cherry Blossom" boot polish. Steam is produced by means of a Briggs gas boiler; and this steam is carried round the vessels containing the polish, keeping it in a melted condition, and enabling the tins to be readily filled. The whole of the process of the Chiswick Boot Polish Company is of extreme interest to visitors to the Exhibition.

National Milk Publicity are also using gas in connection with their exhibit. It is employed for various purposes of pasteurization, &c., and their call has been for a 50-light meter. Virol, Ltd., are taking gas for the heating of the necessary urns for the provision of hot water and giving publicity to their product. The Express Dairy Company have also called for larger supplies. Messrs. Birds have now two "Regulus" cookers for exhibiting various special products of their manufacture. A supply of gas has been carried into the building used by Planters' Products, Ltd. This was formerly occupied by Messrs. Braby, and is entirely of metal construction. Bovril, Ltd., are using gas for boiling water.

The Canadian National Railway have asked for a supply of gas, as have Glaxo, Ltd., Pure Food Products, East Africa, Port of London Authority, Messrs. Lawrence & Parker, and Kenya Colony. Major Dugdale is using gas in connection with the rearing of chickens. Tea rooms have been fitted-up in Malaya, requiring the provision of a 50-light meter. Australia has considerably extended the use of gas, and an additional service has had to be laid.

The Brentford Gas Company inform us that their sales are satisfactory, and on some days have already been higher than they ever were during the British Empire Exhibition of 1924.

The South Australian Government have engaged Dr. Hyman Herman to investigate and report upon the possibilities of utilizing the brown coal deposits at Moorlands, South Australia. The lease of the land, formerly held by the Tailem Bend and Murray Coal Company, has now reverted to the Crown. An area of 73 miles has been reserved, and the Government have put down eighty-five boreholes. The average thickness of brown coal is 14·8 ft., and the average depth from the surface 79 ft. The total area so far proved by boring is 389 acres, and the brown coal available is estimated at over 8 million tons.

A PLEA FOR CO-OPERATION BETWEEN THE GAS INDUSTRY AND THE TRADER.

By F. CORNELIUS-WHEELER.

TIME was when the gas companies were almost the sole distributors of gas apparatus throughout the country, and rightly so, because the various undertakings made a scientific study of gaseous fuel, selected the right type of apparatus to use in varying circumstances, and devoted careful attention to safe and proper methods of installation.

During the last decade, conditions have somewhat changed, consequent on the enlightenment of the public regarding the advantages of gas for heating and cooking, due to the active and far-reaching propaganda advanced by the industry and the British Commercial Gas Association. The trade is perhaps in a greater degree realizing the possibilities of gas as a means by which household drudgery can be reduced to a minimum, thus adding to the comfort of the people by the elimination of unnecessary labour, dirt, and dust, and removing the cloud of smoke which enshrouds our bigger cities. Anything that can mitigate the smoke nuisance caused by burning coal in the open hearth, which is aggravated tenfold during foggy weather, deserves to receive the widest consideration.

If these facts are accepted, as on reflection they must be, surely the time is now ripe for closer co-operation between the gas industry and the traders, builders' merchants, and ironmongers, who handle all kinds of apparatus designed for domestic heating and cooking. The industry, in the past, has been inclined to regard the development and utilization of gas apparatus as a close preserve, due in a large measure to the inferior articles marketed by the trader, and to the inefficient, and sometimes dangerous, methods of fixing. This state of affairs has been still further induced by the fact that countinghouse economies made the re-sale of reliable gas apparatus by the trader an unprofitable business. The trader, in consequence, unless he be a commercial philanthropist, could hardly be expected to push the sales of gas fires and cookers at the expense of coal grates and cooking ranges, from which he could anticipate deriving a reasonable rate of profit, and allow for overhead and establishment charges.

Until trading conditions are improved, merchants as a whole will be apathetic towards the re-sale of gas fires and cookers, and will devote their energies to pushing the sales of goods dependent on the use of coal.

A brief reference has been made to the faulty methods of fixing gas apparatus by those outside the industry, who sometimes appear woefully ignorant of the elementary principles governing the satisfactory use of gas. It may be argued that legislation should be framed to guard against the evils that may arise through ignorance or avarice; but until such time arrives, it is up to traders to recognize that the standard of workmanship employed by the gas undertaking is the only one that can give satisfaction to the user, and further the development of gas sales. Local co-operation must tend to ensure that the public (and they are the only people really concerned) receive reliable apparatus fixed in a manner conducive to safe, economic, and efficient usage.

As a nation we claim to be progressive; and nowhere is this more apparent than in the gas industry. Progress cannot be achieved by Acts of Parliament alone, but rather by the acts of individuals who successfully combine together to work for the benefit of the community. What eventually benefits the community, must in the end benefit the individual. No one, possibly excepting lawyers, sighs for fresh legislation; but a simple set of regulations dealing with suitable methods of carcassing buildings, running gas services, and fixing gas apparatus should be introduced into all Building Acts and borough and urban council bye-laws. Fatalities have occurred, and will continue to occur, where the fixing of gas appliances is allowed to be carried out by the unskilled, without effective regulations and proper supervision. The harmless but very necessary water pipes and fittings throughout a house are governed by drastic rules and regulations, and are subject to inspection and approval by competent authority. How much more necessary, therefore, that gas should be subject to a simple but efficient set of regulations to protect the consumer and generally to safeguard the industry.

Again, one is continually meeting cases where first-rate apparatus is not giving satisfaction to the user, solely because the piping is inadequate for the duty to be performed. The difference in the initial cost of (say) $\frac{3}{8}$-in. and $\frac{1}{2}$-in. pipe, or $\frac{3}{4}$-in. and 1-in. barrel, is almost negligible, but efficiency can only be attained by careful consideration of the sizes requisite. In all cases where gas is taken into a building, the sizes of piping determined upon should allow for additional apparatus, which is sure to follow if the first installation is carried out in a proper manner. A 50 p.ct. margin may not be too much to allow for future requirements. At the present time there are large numbers of so-called gas heaters, which are marketed for the

purpose of heating an apartment where no flue exists, and which, to ensure portability, are connected to a gas point by rubber rings and flexible tubing. Apparatus of this nature, though the gas consumption per hour is only about 4 or 5 c.ft., cannot be considered hygienic, and will be regarded with a great deal of suspicion by all who have the best interests of the gas industry at heart. It is against faulty installation and the choice of unsuitable apparatus, that the consumer, who is necessarily ignorant of these points, should receive some measure of protection; and future legislation will provide an efficient safeguard.

The housing question will for some years to come be one of the most pressing political problems. The builder of to-day is casting around to discover any methods which will tend to reduce building costs without militating against domestic comfort. As a result of the active propaganda throughout the industry, it is becoming more and more recognized that gas provides an economical substitute for the coal grate where intermittent heating is required—such as in parlours, dining rooms, and bedrooms. Not only is gas a more economical fuel than coal for occasional use, but the builder is ready to appreciate the fact that considerable structural and financial savings can be effected by the elimination of ordinary coal-fire construction, and the substitution of narrow flues contained in the thickness of the external or cross walls. This system eliminates the large projecting chimney-breast incidental to the coal flue, thus giving a greater floor area—an important point where the sizes of rooms have to be cut-down to a minimum, owing to the present-day cost of building. These new and beneficial methods of flue construction have received the official approval of the Ministry of Health, the London County Council, and other public bodies.

It is not the writer's intention in these few remarks to offer any suggestions as to the best method of obtaining closer co-operation between the gas industry and the trader, builders' merchant, ironmonger, and builder, because this must be governed in a large measure by local conditions; but if it to some degree ventilates a subject on which many highly-qualified writers can express their opinions, the air would be cleared, and a spirit of mutual co-operation would be created, which would help to sound the knell of the coal grate, and improve generally the conditions under which we live.

RECOVERY OF PHENOL FROM EFFLUENTS.

Herr Peter Franke, of Essen, in "Das Gas und Wasserfach" for April 18, dealt with various methods of extracting phenol from the effluents of gas-works, coke-ovens, &c., with a view to eliminating the harm which it does to fisheries and agriculture. Of numerous processes which have been tried, he selected for mention only those which have been commercially proved, in which the costs are covered by the value of the phenol recovered, or even a profit is shown.

In dealing with considerable quantities of effluents, the separation of the phenol is based upon its solubility in benzole, its homologues, or trichlorethylene. An intimate mixture of the liquor containing the phenol with the solvent is essential, and the subsequent separation of the liquids is easy in view of the different specific gravities. The separation of the phenol from the benzole solution is effected by precipitation with caustic soda, or by heat.

Recovery from Alkaline Liquors.

In fig. 1 is shown an arrangement suitable for use in connection with the ammonia plant of a bye-product works. In

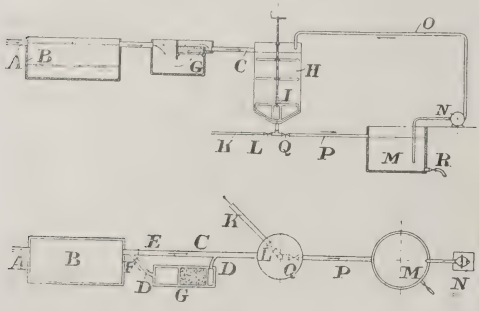


Fig. 1.

such a case it is necessary first to acidify the liquor to be treated, and, for this, waste resinous products are generally available. The waste liquor arrives by *a* into the settling basin *b*, in which solids, such as lime sludge, are deposited. The greater portion of the clear liquor flows through the pipe *c*, while a smaller part is trapped by the connection *d*. The quantity of the latter is regulated by the valves *e* and *f*, and it flows through the filter *g*, which contains the acid resins, from which it takes up sufficient acids to neutralize the main stream in *c*. The liquor, thus neutralized, reaches the washing and mixing apparatus *h*, which is provided with a stirring arrangement *i*. The washer is half full of benzole, and is filled up with the liquor, and the inlet then closed. By stirring for several minutes, an intimate mixture is effected, and the liquor subsequently separates-out at the bottom, while the benzole, which has dissolved the phenol out of it, remains on top. The latter stays in the washer, while the waste liquor is run-off through the pipe *k*.

From the collecting tank *m*, sodium hydroxide is raised, by means of a pump *n*, and by way of *o*, to the washer *h*. Here a quantity equal to that of the waste liquor treated is stirred for a few minutes with the benzole. The latter, thus freed from phenol, again separates-out on top, and the sodium hydroxide is run-off into the tank *m*, by way of the cock *q* and the pipe *p*. Part of the sodium hydroxide combines each time as sodium phenate; and, when this process is sufficiently advanced, the contents of *m* are run-off at *r*, and more sodium hydroxide is introduced. The sodium phenate can be disposed of to the chemical industry, and the only loss of benzole is due to any evaporation there may be, and any slight traces of solubility in water.

In order to save the slight cost of acidifying the waste liquor, it is suggested that the process may sometimes be applied to the ammoniacal liquor itself before this has been treated. In this way, also, considerably more phenol can be recovered.

Recovery as Crude Oil by Distillation.

The apparatus sketched in fig. 2 consists essentially of a distillation vat and several washing compartments, arranged

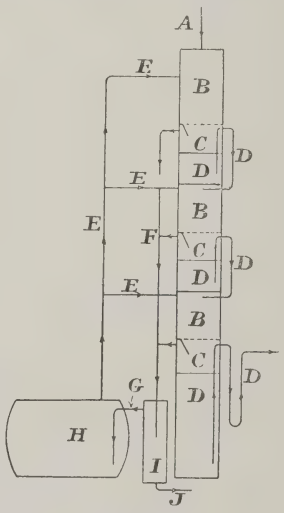

Fig. 2.

A. Liquor inlet.
B. Wood shavings.
C. Benzole.
D. Liquor.
E. Benzole vapours.
F. Phenol-benzole outlet.
G. Phenol-benzole overflow.

I. Separation tank.
J. Liquor outlet.

one above the other, with phenol separators. Each is divided into two spaces, the upper being filled with wood chips or other material, in which the benzole vapours come into contact with the liquor containing phenol, and the lower being that in which the liquor and the benzole separate from one another. The plant includes also a collecting separation tank, where any liquor which has gone through with the benzole can finally settle.

The liquor enters first into the top chamber, and comes into contact with the benzole vapours, which absorb the phenol. In the lower compartment, the benzole-phenol solution and the liquor separate, owing to their different specific gravities. The former runs-off by the central pipe to the collecting separation tank, while the liquor, still containing some phenol, runs into the second chamber, where the process is repeated. After passing the third chamber in the same way, the liquor is as good as cleared of phenol, and can be disposed of direct from here; and any of it that has passed over with the benzole to the collecting

tank will separate out there, and can be run-off at the bottom for disposal. The benzole-phenol solution passes by an overflow into the distillation vat, where the benzole is vaporized and returns to the process, while crude phenol oil only remains.

A Liquid Benzole Process.

Fig. 3 indicates the apparatus for a combined liquid and vapour process. The separation of the phenol from the benzole is done by heating, while the benzole is introduced to the liquor in liquid form. Before being mixed with the benzole, the liquor flows down from a high storage tank through a condenser and a dephlegmator. In this way it is warmed for the process of phenol extraction, which is thus expedited. By means of a pump, the benzole is introduced at the lower end of a mixing tank, which is fitted with Raschig rings or other packing, while the liquor enters at the top. With its lower specific gravity, the benzole rises, and the liquor moves in the opposite direction. Working in this way, a very efficient result is achieved, especially as the fresh benzole entering the mixer first comes into contact with the liquor when the latter has already given up most of its phenol.

The benzole, after taking-up the phenol, passes into a distillation apparatus, where it is vaporized, and from which the crude phenol oil is run off. The benzole vapour then passes through a space filled with Raschig rings, and a dephlegmator, where any remaining particles of phenol are retained. It is then condensed, and returned to the process.

Trichlorethylene.

The use of trichlorethylene, either in liquid or vaporous state, has the advantage over benzole and its homologues that it is not highly inflammable, and is not even slightly soluble in water, so that not even slight traces are lost in this way in the process. In coke-oven works, however, no doubt the benzole produced locally will be preferred. It has also been found on occasions that trichlorethylene in mixture with water gives rise to corrosive troubles, due to formation of free hydrochloric acid.

Payability.

The author estimates the payability of the processes on the basis of treating liquor containing 0·5 p.ct. of phenol. With a 90 p.ct. efficiency, 45 lbs. of crude phenol oil are recovered from 1000 gallons of effluent, requiring the vaporization of 300 gallons of benzole by about 0·27 ton of steam. On these figures, he considers the process quite profitable, having due regard to cost of wages, depreciation, &c., and that, far from being an added charge, it improves the showing of the bye-product plant.

INDUSTRY AND SMOKE ABATEMENT.

At the Annual Conference of the Royal Institute of Public Health, which was held at Brighton last week, Mrs. M. A. Cloudesley Brereton, in collaboration with Mr. Ian Macdonald Horobin, M.A. (Hon. Warden, Mansfield House, University Settlement), read a paper entitled "Industry and Smoke Abatement."

Industrial Smoke: The Next Step.

My view, says Mrs. Cloudesley Brereton, is that we cannot tackle the domestic smoke problem in any but a very gradual way. We can only concentrate on educational propaganda about smoke; leave the gas and electric industries to go on winning public favour; enlist the intelligent co-operation not only of doctors, but of architects and builders; and wait upon Science to solve the problems of large-scale production of a cheap free-burning smokeless solid fuel. Because we have to wait in this, does it follow that we should also wait to tackle industrial smoke, for which in many cases remedies are to hand? I think not. But let us, whatever we do, avoid making industry hostile to appeals for reform, by being deaf ourselves to the reasonable appeals of industry for caution.

Lord Newton's Smoke Abatement Committee drew a perfectly sound distinction between smoke from boiler furnaces and smoke from other manufacturing processes. Well over half the industrial smoke comes from the former source, and generally speaking this may be dealt with as a single problem, irrespective of the industry in which the steam-raising plant is used. It is not possible, however, to fix a definite limit to the amount of density of smoke permitted from boiler furnaces, which should be universally applicable, since the type of the existing plant, and the size and constancy of load, variously affect the possibilities of smoke prevention. Such measures as were contemplated in recent Smoke Abatement Bills are, therefore, the best that can be reasonably imposed—measures whereby an emission which "constitutes a nuisance" shall not entail a fine if the manufacturer is able to show "that he has used the best practicable means for preventing the nuisance, having regard to the cost and to local conditions and circumstances."

It might be profitable for the Minister of Health to invite the opinion of industries on a proposal to set a time limit to the operation of such regulations, after which they would be replaced by a definite and stringent standard of maximum smoke emission permissible from boiler plants, irrespective of cost and local conditions and circumstances. In other words, those firms whose boiler plants are at present not capable of preventing smoke as effectively as others would be given a definite period of so many years in which to adopt new plant, new methods, or special devices for the prevention of smoke.

I do not pretend to know how such a suggestion would be received by industry. My main point, indeed, is not to recommend that such measures should be taken, but that industry should be invited to co-operate with the Minister in offering advice as to what is and what is not practicable. The Ministry of Health is, I believe, alive to the necessity for consulting industry. I only stress the point because some zealous reformers are not. And such zealous reformers do harm.

The same principle of taking the views of industry is even more applicable to smoke from manufacturing processes other than steam raising. I would suggest:

(1) That the Minister of Health should appoint permanent committees composed of leading progressive manufacturers in individual industries (or groups of industries which can fairly be treated together) to advise him as to the minimum of smoke which it is practicable to emit by employment of efficient methods in reasonably up-to-date plant in the processes concerned.

(2) That a fuel expert of recognized standing be included, besides business men, on all such committees.

(3) That the minimum smoke emission practicable, as defined by these committees, should be scheduled by the Minister as maximum standards of permissible smoke emission.

(4) That legislation be enacted making it obligatory upon local smoke authorities, having power over larger areas than those responsible at present, to prosecute when these maximum standards of smoke emission are exceeded.

(5) That, as suggested in recent Bills, it should be a defence to show that the best practicable means had been taken to prevent emission of smoke in excess of the standards.

(6) That, for the benefit of manufacturers and the guidance of judges in prosecutions, the committees should be invited to draw-up instructions to show by what methods it is practicable to reduce smoke to the standards set up on their recommendation.

The spirit of this recommendation is, I am sure, a right one.

(7) That the Minister should further allow and encourage local authorities, in consultation with the local chambers of commerce, to set-up local committees representative of industry in their area; and that the principal functions of these committees should be to encourage local *voluntary* standards higher and more exacting than the national standards set-up by the Minister on the recommendation of the national committees.

If the problem of industrial smoke is approached along such lines, effective legislation should be practicable—not legislation that would impose new burdens upon industry at this unfitting moment, but legislation of a kind positively helpful to industrial progress.

SOUTHERN ASSOCIATION OF GAS ENGINEERS AND MANAGERS.

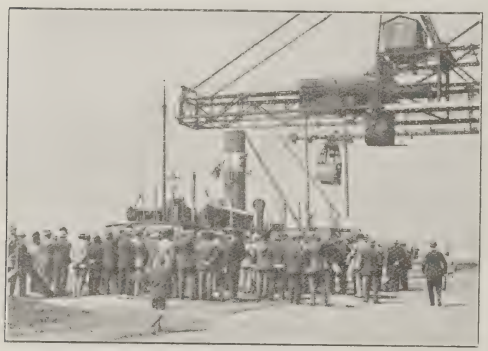
THE BOURNEMOUTH GAS AND WATER COMPANY.

The Summer Meeting of the Southern Association took place in Bournemouth last Friday, when a large number of members assembled to enjoy the hospitality of the Bournemouth Gas and Water Company, and to visit the works of their President, Mr. P. G. G. Moon, F.C.S. Perfect weather favoured the occasion, the hospitality was of a most generous order, and keen interest was taken in the bold construction work at Pitwines, Poole.

The rendezvous was the Square, at 10 a.m., whence the party were conveyed in motor coaches to Poole, traversing the Pitwines site and disembarking on the quay where coal is unloaded for the old works. It will be remembered that the Bournemouth Company acquired the undertaking of the Poole Gas and Coke Company in 1902, and in 1905 extended the harbour site to 3¼ acres.

THE WORKS.

The coal is unloaded by two bridge transporters. The original one, which was supplied by the Temperley Transporter Co. (now amalgamated with Sir Wm. Arrol & Co.) has a nominal capacity of 50 tons per hour, and has worked continuously since it was first erected in 1905. The operator sits in a fixed cabin, the grab being controlled and travelled by wire ropes. The second transporter was supplied by the Mitchell Conveyor Co. in 1922, and has a capacity of 100 tons per hour. It operates on a rather different principle, as the driver, instead of being in a fixed cabin, travels with the grab,



Mitchell Transporter at Work.

and thus has better control over the operations of the crane, while a further advantage is that the wire ropes required are much shorter than with the Temperley transporter.

The transporters have a span of 180 ft. over the coal store, and a cantilever span, over the public road and two railway lines, of 116 ft. They travel transversely across the coal storage ground and enable coal to be dumped upon and picked up from every portion of the area. The coal is lifted from the hold of the ship by means of grabs; and when both machines are working, a vessel can be unloaded in 10 hours, including all stoppages for greasing, trimming, &c. The transporters can deliver coal either from the ship or from the stock heap through the coal breakers and fillers to the gravity-bucket conveyors which convey it to the overhead bunkers in the retort houses.

The carbonizing plant consists of: (*a*) One house containing 100 23 in. by 16 in. by 21 ft. through retorts, equipped with De Brouwer charging and discharging machines. The capacity is 1½ million c.ft. per day. The coke is removed by a hot coke chain conveyor, and stored in ferro-concrete hoppers with a capacity of 280 tons. (*b*) Two houses containing three benches of Woodall-Duckham verticals, each bench having 24 retorts, 25 ft. long. The capacity of each bench is 1¾ million c.ft. per day. Two Bonecourt waste-heat boilers have been installed, with a capacity of 4200 lbs. of steam per hour.

The coke is brought from the vertical retort houses by gravity-bucket conveyors encircling the benches, and is screened and graded before being dumped into the storage hoppers. These have a capacity of 450 tons, making with the horizontal hoppers a total storage of 730 tons.

To deal with the coke required by the water gas plant and boilers, there is a Mitchell 3-ton radial cantilever crane with a radius of 70 ft. and a height of lift of 45 ft. The operating cabin of this crane travels with the load, and thus control is very much easier than from a fixed cabin on the framework. The crane puts the coke required by the water gas plant and boilers direct into overhead storage hoppers serving these plants, deals with the ashes from the retort houses, boilers, and water gas plant, and will also feed a loading station on the new cableway conveyor to Pitwines.

The coal handling plant and the radial crane are of outstanding interest, and received much comment from the visitors. Their attention was next called to a Scammell "Six-Wheeler" motor trailer, which ran quietly into the yard and with the minimum of fuss deposited its heavy load of coke in a neat stack on the ground. The trailer frame of this machine carries a long pressed-steel body mounted in trunnions at the rear; and the load is tipped by raising the body on the piston-rods of hydraulic

Scammell "Six-Wheeler" Unloading.

or oil-pressure cylinders, the power for which is developed by the motor engine through a suitable clutch and gearing. The "Six-Wheeler" has a capacity of 10 tons, and is used by the Bournemouth Company for transporting coal or coke to the Bourne Valley Station or the water-works.

An adjournment was soon made, by way of the new ropeway passage, to the Pitwines site, where the progressive policy of the Directorate and the ingenuity of their Engineer and the contractors are rapidly bringing to completion one of the finest gas-making stations in the country—on a site largely reclaimed from the sea for harbour works. Col. Harold Woodall, when Engineer to the Company, built the 2¾ million holder on the only clay he could find; and the piling which has been carried out to make extensive works possible on the site was a task requiring great skill and patience. Full details of this, as of the design of all the new plant, were included in the supplement which Mr. Moon gave to his Presidential Address at the Annual General Meeting on March 24 [see *ante* p. 117].

Large-scale drawings were posted up by every section of the plant, and the visitors were ably guided and fully informed on any matter by members of the Directorate, Mr. Moon, and his assistants and staff, who are to be cordially thanked for their services. Time was too short, however, for a thorough inspection of the many features; and it is hoped that an opportunity will one day be granted for another visit when the station is at work.

The Poole Works on the Left; the Pitwines Works on the Right.

PITWINES—NORTH-EAST ASPECT.
Showing the 15,000-ton coal store, the ropeway terminus, and the Woodall-Duckham verticals.

The 15,000-ton coal store, with its conveyor on a travelling gantry, was first viewed. At one corner the shuttering for the concrete of the terminal station of the cableway was in position. Here, automatic devices will tip the buckets into one of three hoppers—for coal, coke, or ashes. Next for inspection came the Woodall-Duckham verticals—capacity, over 2¾ million c.ft. a day. A new setting, not yet fired, offers the fullest opportunity for the examination of details of construction and mechanism; and the majority of the visitors made a tour of each stage, and on the charging level had the advantage of explanations of the latest developments from Sir Arthur Duckham himself. A new feature at ground level is extraction of the ashes from the hanging-bar producer grates by gear similar to that for coke extraction from the retorts.

One two-million Humphreys & Glasgow C.W.G. plant is in course of erection at the end of the main block of buildings. The "house" is very spacious, and it is probable that in due course the water gas plant from the Poole Station will be shifted into it. Automatic chargers and self-clinkering grates

LEFT TO RIGHT: Mr. Plumb, The Mayor of Bournemouth, Lt.-Col. H. W. Woodall, The Mayor of Christchurch, Sir Charles Jessel, The Mayor of Poole, Mr. E. Honoratus Lloyd, Sir Charles Morgan, Mr. P. G. G. Moon.

will be applied to the new units. The boiler house is adjacent; and the ash shaft between this and the C.W.G. house excited considerable comment. Alongside the boilers are the Dowson suction producers which supply the power house, so that the solid fuel using plants are grouped together.

The power and exhauster house is an admirable piece of work; and fortunately the engines were seen running—on town gas for the present. They form part of a large Keighley Gas Engine Company contract for producers, engines, dynamos, compressors, and auxiliaries, and are of the latest pattern with gas and water supply below ground level and visible cooling water feed. Two generating sets are complete, and the power section of the house has been designed for two more, besides the auxiliary plant. The main switchboard is not yet in place. The exhausters—three out of six by G. Waller & Sons, each of 125,000 c.ft. per hour, are installed at present—are on a platform nearly the full length of the house, and about one-third its total width. Three lines of mains are readily accessible between the platform and floor level. Over the power units runs a 2½-ton crane, and over the exhausters one of 1 ton capacity; and it was pointed out that a gap, which will be screened, has been left in the dividing wall between this house and the adjacent workshops. This opening is big enough to pass the largest single part of the power plant.

In these few notes an endeavour has been made to record the features which specially attracted attention, for the whole scheme was admirably dealt with by the President in his address.

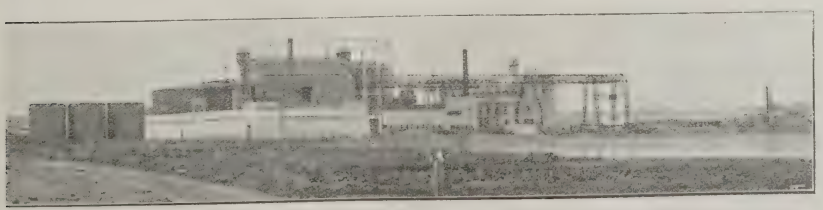
THE LUNCHEON.

Light refreshments having been served, the visitors made their way past the booster and purifier houses to the main entrance of the new site, where the motor coaches were waiting to convey them to the Branksome Towers Hotel. Here they were the guests at luncheon of the Chairman and Directors of the Bournemouth Gas and Water Company.

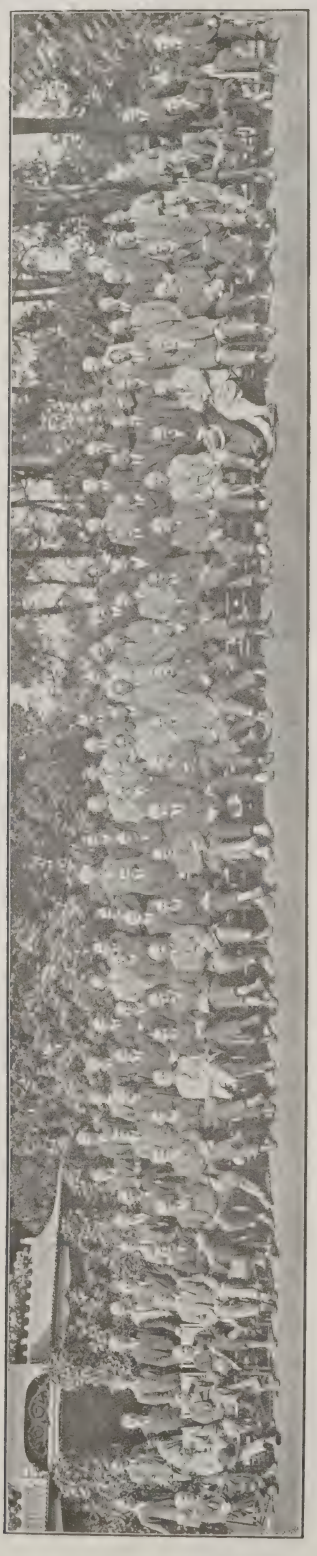
Mr. William Cash, F.C.A., was in the chair, supported by Sir Charles Morgan, C.B.E., M.Inst.C.E., Sir Charles J. Jessel, Bart., Col. H. Woodall, C.I.E., M.Inst.C.E., and Mr. E. Honoratus Lloyd, Directors of the Company. With them at the top table were their Worships the Mayors of Bournemouth, Poole, and Christchurch; the President of the Association, the Vice-President (Mr. R. Robertson, of Bristol), and the Secretary (Mr. H. C. Smith, of Tottenham); and Sir Arthur Duckham, K.C.B., Mr. Thomas Hardie (Chief Engineer of the Gas Light and Coke Company), and Mr. W. M. Mason (Manager of the "B.C.G.A."). The following were unfortunately prevented from attending: Mr. J. Ferguson Bell, the Presidents of the North British and Midland Associations, Dr. Lewis Bailey (Chief Inspector of Alkali Works), Mr. F. Napier Sutton, and Mr. W. B. Leech (Engineer of the Beckton Station). The Loyal Toast was honoured at the call of the Chairman.

POINTS FROM THE SPEECHES.

The CHAIRMAN proposed "The Southern District Association of Gas Engineers and Managers." To them he extended a hearty welcome to Bournemouth, and on behalf of the assembled company voiced appreciation of the presence of the Mayors of Bournemouth, Poole, and Christchurch. Nowadays the gas engineer had to be a man of high efficiency and training. Besides gas-making, his duties demanded a knowledge of all branches of mechanical and constructional engineering, and of chemistry and electricity. On the administrative side he had to deal not only with his men but with the consumers; and commercial training was necessary for buying and selling such things as coke, sulphate of ammonia, and tar. Added to this at Bournemouth was water engineering, with its many problems. He sometimes wondered the Engineer did not get confused, fill his holders with water, put his gas through sand filters, soften the gas, and attempt to purify the water with oxide. [Laughter.] These Association meetings gave opportunities for the exchange of ideas and the examination of new processes. He had been interested to note that Mr. Moon had touched on several processes of purification, oil cracking, &c., in his presidential address. With the toast he coupled the name of Mr. Moon. The Directors were highly gratified



and the Intervening Streets through which the Ropeway Conveyor will run.



THE LUNCHEON PARTY ENTERTAINED AT THE BRANKSOME TOWERS HOTEL.

at his being elected President of the Association. The greatest credit was due to him for his design and planning of the new works—carried out without the aid of a consulting engineer. Mr. Cash made appreciative references to Col. Woodall, whose presence on the Board was of such advantage to them; and to Sir Arthur Duckham, once on the staff of the Company—they felt proud that he was with them that day. They were proud, too, that the Engineers of Croydon, Barnet, and Worthing were old Bournemouth men. They had always had first-class officers.

The PRESIDENT replied. On behalf of the Southern Association he thanked the Chairman and Directors for their great hospitality. In his opinion these meetings were able to be of value because the gas industry was not hampered by internal competition, and what he might call the territorial limitations of gas companies allowed free discussion on methods and efficiencies. Gas engineers realized that they were all together, not merely to sell gas, but to render public service. He appreciated the broad outlook of his Directors, who understood that gas engineers could not get on just by watching their holders go up, but that they had to go about and discuss things elsewhere.

Mr. R. ROBERTSON, of Bristol (Vice-President of the Association), gave the toast of "The Local Boroughs;" and, incidentally, amused the company. On their busman's holiday, he said, they had been trying to find the secret of success which attended the Bournemouth undertaking; and he thought they should put the Bournemouth Company on to show the electricity industry how to develop their business without a subsidy. In eulogizing the boroughs of Bournemouth, Christchurch, and Poole, he found a point of similarity between the latter two—at Christchurch the Priory, at Poole the gas-works! Both were responsible for the dissemination of light; and, if he might say so, both had something to do with heat—one showed how to produce it, the other how to avoid it.

Their Worships the MAYORS responded; the Mayor of Bournemouth congratulating the Company upon their enterprise. In his younger days the site of the Pitwines Works was nothing but harbour mud. His Worship of Christchurch remarked that a few years ago they had had the good sense to change from electricity to gas, and they had no reason to complain. The Mayor of Poole said that the Company provided one of the links between the boroughs. Poole had fine opportunities for expansion, and one day it might be a larger consumer of gas than Bournemouth.

The Chairman with Engineers of Companies in which he is interested.

LEFT TO RIGHT: Mr. P. G. G. Moon, Mr. S. O. Stephenson (Worthing), Mr. Wm. Cash, Mr. W. J. Sandeman (Croydon), Mr. A. Caddick (Croydon), Mr. Hasledine (Barnet).

Sir ARTHUR DUCKHAM, K.C.B., proposed "The Bournemouth Gas and Water Company." As an old Bournemouth man, it gave him great pleasure to give the health of the Company; and he was delighted to see present two of his old chiefs—Col. Harold Woodall and Mr. T. S. F. Gibson. He considered that the Bournemouth Company had done more than any other for the progress of the industry. Two points of their policy especially struck him. The first was that they had led the way in establishing the new relationship between gas companies and their consumers, which had at one time been very different from what it was now. The second point was that they had always shown great courage and a wealth of ideas. He felt sure that Mr. Moon would have one of the finest works in the country.

Mr. WILLIAM CASH responded for the Company. Kind things had been said about the Board of Directors, which, he confessed, comprised experts in almost every relevant direction. In this regard Mr. Cash mentioned specially Sir Charles Morgan, a great engineer, Sir Charles Jessel, financier and gas administrator, Mr. Honoratus Lloyd, K.C., and Col. Harold Woodall, with his local knowledge. The Company's great problem was to meet the growth in the demand for gas. In 1894, their output was 208 million c.ft.; in 1904, 527 millions; in 1914, 1016 millions; in 1924, 1791 millions. In 1904 they had 14,149 consumers, and in 1924 36,362. The charge on the capital was, at present, no more than pre-war. After mentioning the Company's co-partnership scheme and their service of the consumer, Mr. Cash concluded with a reference to the charms of Bournemouth and the adjacent boroughs.

Mr. MOON, at the close of luncheon, announced that in the course of the afternoon's drive they would pass the Swanage Gas and Elec-

tricity Works—an excellent example of the joint supply of the two commodities. He pointed out that since the inception of joint working there had been an increase of 117 p.ct. in the consumption of electricity, and at the same time an increase in gas consumption.

The band of the Bournemouth Gas and Water Company played, on the lawn of the hotel, an excellent programme of music during and after luncheon; and a photograph of the party was taken before leaving for the drive. The latter, in the perfect summer weather which favoured the visit, was to Swanage, and led by Corfe Castle and through a countryside full of natural features of interest.

It is needless to say that the visit was greatly enjoyed by all present, and that many thanks are due to the Bournemouth Gas and Water Company, to Mr. Moon, Mr. Smith, and all who worked to make it a success; and the large attendance of members and visitors must have been gratifying to the hosts, especially in view of the visit's immediate proximity to "Institution Week."

CALORIFIC VALUE AND GAS TESTING.

By NORTON H. HUMPHRYS.

The observations under this heading (see *ante*, p. 528) comprise items with which all who have had practical experience in manufacturing and supplying gas subject to the provisions of the Gas Regulation Act are likely cordially to agree; but also some that may be regarded as of doubtful character. Objection will not be made to the soundness of a proposition that the gas sent out from any one works should be uniform in calorific value and specific gravity (to which the supply pressure at the inlet of the consumer's meter might be added), or to the inadequacy of official tests, no doubt correctly conducted, but so far apart that they fail to indicate a fair average, and may consequently tell against uniformity. At an early stage of experience in carrying-out the requirements of the 1920 Act, on a small works where the official visits were limited to four per annum, the fact was evident that the official annual average might differ by as much as ten units from the average of the works bi-weekly tests, a sufficient margin to cause undeserved stigma of liability to penalty; and that, under such conditions, the costly and cumbersome official calorimeter set is a white elephant, so far as official use is concerned. That it will be a great acquisition to an intelligent and energetic manager is another story. Better and more satisfactory results could be secured by the weekly or bi-weekly use of a simple, self-contained, and portable direct-reading apparatus that could be operated by any intelligent lad, of which appliances several varieties, claimed to be accurate within 2 p.ct., are now on the market. The average of the daily readings obtained from an instrument of this class is at least as near the mark as the official four-item annual average.

Where is the need for a costly and elaborate set of apparatus, if the operation procedure is such that the results obtained by it are not within 2 p.ct. of a correct presentment?

As a means of securing information respecting the extent of amplitude between maxima and minima, also as affording a portable and comprehensive record covering a period of years, which may be placed on view in the office or board-room, the graph illustrated on page 529 can be highly recommended. Weekly readings are readily included on a sheet of moderate dimensions, covering the entire year's operations; and three or more years may be shown on the same chart, by the use of different coloured inks. The facility for comparison is far greater than can be afforded by paged record, and a useful addition is a blank space at the foot, for entry of averages, coal used, and other details.

According to personal experience, a jump of 40 B.Th.U. or more between the quality one day and the next is both undesirable and avoidable. I have never met the obsequious consumer who takes off his hat and expresses polite gratitude for a reduction of 100 B.Th.U. or so in the quality of his gas supply; but have reason to believe that fluctuations extending to 40 B.Th.U. or more create dissatisfaction that is none the less real if not definitely stated to the clerk at the complaint counter or to the meter inspector. Many consumers have an innate dislike of making complaint, or believe the same to be useless, but they are impressed with the difficulty as an inherent and unavoidable defect peculiar to town gas, and business is thus prejudiced.

In exceptional circumstances, an undertaking "under excellent management" may be compelled to supply some 30 B.Th.U. below the declared value for a sufficient time to necessitate a corresponding swing of the pendulum in the other direction in order to recover the average. But that such is a fair generalization as applied to everyday practice throughout the country, I do not believe; having found that an output of 25 million c.ft. per annum can be comfortably worked, year in, year out, within a 25 B.Th.U. margin, which, as experience accumulates, will doubtless be reduced. The facilities for uniformity increase with the scale of operation. Any engineer, excellent or otherwise, who exceeds 20 to 25 B.Th.U. may be advised to give full attention to the causes of variation.

There is room for wide differences of opinion respecting the need for, or the advantages obtainable by, the adoption of one compulsory standard of calorific value throughout the country. Its advocates occupy an ambiguous position. Some seem to regard it as a new thing, forgetting that the gas industry had settled down for at least 25 years prior to 1920 to a uniform 14 candle (No. 2 "Metropolitan" burner) illuminating power, and that a national standard has thus been afforded a prolonged trial. For various reasons some exceptions existed, but the extent to which the 14 candle standard was adopted amply sufficed to illustrate the advantages or defects inherent in one fixed standard. Among other things, a leading feature in the Gas Regulation Act, 1920, is an advance on the uniform quality, in response to complaints as to the limitations thereby involved, in the way of free selection of materials and processes, towards giving the consumer the best possible value at the least cost. With continual increase both in extent and variety of the available materials and processes, this objection is not less important in 1925 than 1919. The 14 candle quality was arraigned both at the works and on the district. The works manager had one hand tied behind him; and 14 candle was not necessarily the best for the consumer. The Act introduced full liberty in respect of both these matters, not only at the start, but for alteration, if thought desirable, at reasonable intervals. Up to the present, undertakings coming under the 1920 Act have followed the line of least resistance, for the greater part, and continued to work without important alteration to existing practice, not accepting a declared value that varies from 14 candle (considered to be equivalent to 500 B.Th.U.) by more than 10 p.ct. One reason may be that gas undertakings were for the most part crippled by war conditions and needed to recover normal status before considering important changes; or thought that the wiser plan was to await better facilities in the matters of material and labour. Many who are inclined to take advantage of the new regulations do not at present feel at liberty to do so, and the majority who retain practically the former quality would be ill-advised to discard lightly the wider door opened by the 1920 Act; for, when clear of present embarrassment, they may have opportunity for full consideration of the value that would secure the greatest advantage both to their customers and to themselves.

If there exists such a thing as one fixed value that is equally desirable under all the various conditions of gas consumption, it will gradually acquire increased importance and prominence as the survival of the fittest; but the abandonment of all the benefits to the industry which are attendant on the right to change the declared value at any time is a heavy price to pay for the doubtful advantages that would follow the adoption of a national standard, and which, by the way, were not strongly in evidence at any time previous to 1920—nor has anything to the contrary been specially noticeable at a later period.

The clauses in the 1920 Act were not intended for the exclusive assistance of the undertakers. The interests of the consumers were viewed in correct perspective. While there is little difficulty in making out a case, on their behalf, in favour of full liberty, it is not such an easy matter to plead the cause of a national standard. The authors of the 1920 Act correctly assumed that, as business men, the directors of gas undertakings, so far from seeking to force an unacceptable value which for other reasons might be desirable, would look for one that would promote sales by giving general satisfaction. The introduction of one fixed value throughout the country would in many cases call for more extensive changes in the way of replacing existing pipes, fittings, and burners than have been necessitated by the operation of the 1920 Act. Consumers would not be willing to bear the expense. Many gas undertakings would be forced to accept responsibility for large outlay which did not carry corresponding advantage, and might result in actual loss.

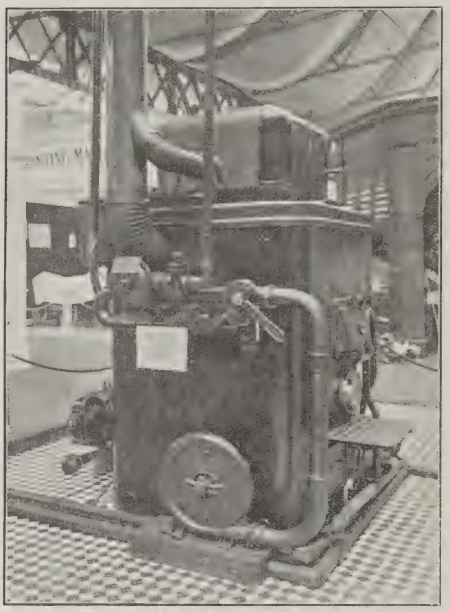
Much has been said about the selection of any Tom, Dick, or Harry as capable of efficiently carrying out the duties of an official gas examiner, with little or no regard to qualification. To quote one instance, a point was made of the selection of the owner and occupier of a small public house. The fact that the accepted candidate was a retired master gas apparatus erector, who, after many years of travelling, desired to settle down in quiet, but possessed an intimate knowledge of the gas industry and had at times taken entire charge of a gas-works, was evidently unknown to the objector. On the whole the appointed officials appear to have discharged their duties to the satisfaction of all parties concerned; and I have not heard of any returns being disputed on grounds of incompetence or negligence. The only objections hitherto published take the form of irresponsible comment by aggrieved parties who have experienced trouble with the gas supply, due to local defects, or, after a few years' enjoyment of a "slow" meter, have been provided with a substitute that complies with the requirements of the Sales of Gas Acts.

Smoke Pollution and the Nations.—The Czechoslovakian Academy of Agriculture have put a proposal before the International Institute of Agriculture at Rome for the establishment of an international commission to study legal and other measures for the prevention of damage due to smoke.

PRINTERS' EXHIBITION.

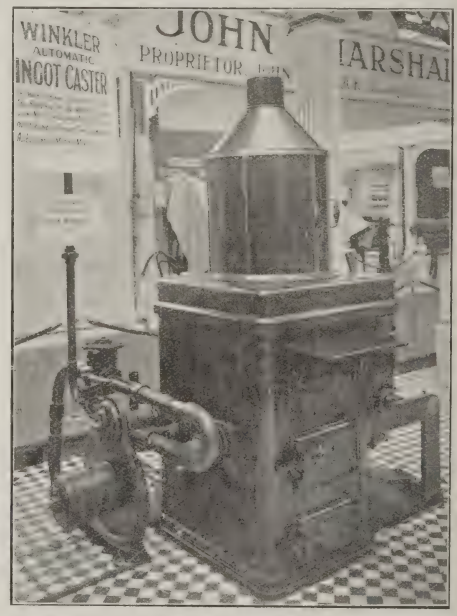
Use of Gas in the Trade.

The ordinary member of the general public cannot help but be surprised at the scope of the printing trades. There is no industry which has developed more rapidly in recent years than the printing industry; and Britain does not lag behind in this respect. It is not necessary here to go into any detail in connection with this specialized trade; but it is interesting to note, from the point of view of our own gas industry, that the printing trade has been almost fully converted to the use of gas wherever the employment of that fuel is possible in their industrial processes. It is also interesting that some of the most recent advances in printing machinery have incorporated, where possible, gas firing equipment, and that the literature supplied by such makers of complicated machinery includes accounts of the advantages of the use of gas on their machines.



The Winkler Automatic Casting Machine.

It is not generally realized that the printing trade in London has been converted to the use of gas. There were on view at the Printers' Exhibition, recently held at the Royal Agricultural Hall, the latest applications of gas in the printing trade. Practically the whole of this development has occurred during the last three years; and this has been made possible by demonstrating that gas can be applied to large-scale metal melting with enormous advantages over solid fuel, and by introducing equipment which requires for the same work done anything from 20 to 50 p.ct. less gas than was previously the case.

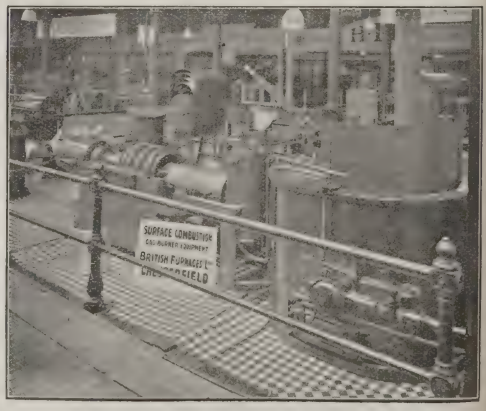


The Winkler Automatic Ingot Caster.

On the stand of Messrs. W. J. Light & Co., of Nos. 36-38, Whitefriars Street, London, E.C. 4, were the Winkler automatic casting machines, which are claimed to have the biggest outputs of any appliances on the market. Metal was being melted and cast at the rate of 200 lbs. of stereotype per minute, which is 33 p.ct. above the normal capacity of the machines. The gas consumption on this furnace is 570 c.ft. per hour during the working period of 6 hours, and 60 c.ft. per hour during the rest of the 24 hours when the metal is kept in a molten condition. The pot has a capacity of 2 tons of metal; and this quantity is melted-down, and raised to a temperature of 600° Fahr. in 1 hour from cold. The gas consumptions on this furnace can be taken as being 1 c.ft. for 10 lbs. of metal melted during the working period, and 1 c.ft. for each 6 lbs. melted when the gas consumption during the 18-hour holding period is taken into account. The furnaces are well insulated, and are heated by means of burner equipment supplied by British Furnaces Limited, of Chesterfield; the gas being at town pressure, and the air at 12 in. pressure.

Another piece of equipment shown in actual operation on the same stand was the ingot caster. Similar results are obtained

A Stand showing Three Gas-Fired Furnaces.



The Pony Autoplate.

by means of gas to those obtained from the automatic casting machine. The capacity of the pot is 900 lbs., and it has a bottom discharge. It is claimed that this furnace has the highest output of ingots of any caster on the market.

All plant on this stand having gas-fired equipment was sold on the first day of the exhibition, and further orders have been received from printing offices in Glasgow, Cardiff, Leicester, and Blackpool.

Another of the leading stands showing printing machinery which requires furnace equipment was that of the Linotype and Machinery Company, Ltd., of No. 9, Kingsway, London, W.C. 1. This Company supplied Junior and Senior Autotype machines, and they demonstrated the use of the "Pony" autoplate machine. This equipment was also sold on the first day of the exhibition, and others are on order. Similar efficiencies are obtainable on this autoplate machine to those on the Winkler machine.

The following is a list of some of the newspapers and printing offices in which British Furnaces equipment has been installed: "Daily Express," "Daily Chronicle" (London and Leeds), "Daily News," "The Star," "Daily Mirror," "Daily Sketch," "Evening Standard," "Daily Sketch" (new buildings), Amalgamated Press, St. Clement's Press, Dellagana & Co., Cassell, Ltd., Wm. Clowes & Sons, "Morning Post," "Manchester Guardian," Crabtree & Sons, Leeds, "Sydney Morning Herald," Bell Punch Printing Company, Ltd., "Brighton Herald," "Yorkshire Evening Argus," and "Glasgow Evening News."

There are over 100 installations at the present time in London alone. Most of the equipment consists of specialized burners to which are attached patented inspirators, in which the automatic mixing of theoretical proportions of air and gas is ensured. The equipment requires gas at town pressure, and air from fan pressure. One concern alone in London is saving over 300,000 c.ft. of gas per month in its equipment, as compared with previous apparatus in use; and there has been no case of a cracked pot since the installation of the surface combustion principle. This has brought about a saving in this particular firm's case of about £2000 a year. In the majority of instances, however, the conversion has been made from solid fuel to gas, as few concerns had previously used gas in their processes.

GENERAL SALES PROPAGANDA.

By H. D. MADDEN, Engineer and Manager of the Cardiff Gas Company.

[A Paper before the Wales and Monmouthshire District Institution of Gas Engineers, May 28.]

When our President approached me in reference to a communication for this meeting, I had some diffidence in the choice of subject, but ultimately decided on a paper that would deal with showrooms and the value of publicity and propaganda by the judicious use of such prominently placed premises.

In the first place, the practice has been, and rightly so, to have the gas offices and showrooms in the principal thoroughfares of the town, and to provide the most attractive windows for the display of fittings and general gas-consuming apparatus. The ultimate object of this provision and display is largely, and more often solely, to increase the sales of gas; and it is noteworthy how effective these measures are throughout the country.

Are we content with the present-day business and uses of the showrooms, or shall we ask whether there are potentialities worthy of consideration and development? Unhesitatingly I answer that there are. In the first place, no gas-consuming apparatus should be shown or offered for sale unless it has first been tested and found eminently suitable and efficient in use with the quality of gas supplied to the district. The types should be carefully tested under conditions of pressure, with the actual gas provided; and this should rigorously be kept to a standard calorific value, and regular specific gravity and composition. With care exercised in manufacture, it is possible to reduce to negligible factor figures the limit of deviation from the predetermined values. Recognizing this, the Cardiff Gas Company recently arranged a physical laboratory wherein all domestic and industrial appliances are tested and carefully examined. We are thus able to deal with problems in more exact ways. Moreover, the outdoor staff are afforded every facility to visit this laboratory and gain first-hand knowledge of the methods of testing and the results obtained.

Give the salesman the best and most efficient apparatus, and eliminate all appliances which primarily may appear cheap, but ultimately prove troublesome and inefficient, and thereby cause annoyance, and result in dissatisfied consumers.

The showroom should be the place where the consumer can always call for advice and help, meeting salesmen he knows and who have his full confidence. Remember, also, that consumers call there to pay their gas accounts. If a friendly and good spirit prevails between the officials and the consumers, the company and the industry benefit. Generally speaking, this spirit of service and goodwill does strongly exist, and is being fostered and furthered by the salesmen's meetings and the Junior Gas Associations. Both are doing excellent work in this direction, and also in the education and technical advancement of sales staffs—most necessary factors to-day.

Every employee of the gas company who meets consumers is a potential commercial traveller for the company he represents, be he collector, inspector, or gasfitter; and it is vitally important for the industry that the men in these branches should be carefully educated, trained, and equipped with a sound knowledge of the application of the products the undertaking manufactures. At school we used to write out the phrase "Knowledge is Power"; and this can be applied to the staffs of gas undertakings. Widen the view-point, and give the gasfitters, foremen, inspectors, &c., facilities to see how the gas is made, the care taken in its production and purification, how and why it is tested, and the bearing on its use and application. If this is done, it will be found that the outdoor staff will respond, and take a great interest in their daily routine, to the greater satisfaction of the consumer, and the ultimate benefit of the undertaking. In other words, give them a wider interest than the common round and daily task. Consider the human element, and make them interested and enthusiastic gas men. At the same time offer scope and encouragement to the individual.

In Cardiff, my Directors have tried this. Arrangements were made for the outdoor staff to visit the works in groups, and see the actual manufacturing processes, supplemented by a series of lantern-slide lectures throughout the winter months. These lectures dealt with raw coal, manufacture of gas, production of coke and sulphate, &c., and finally with the application of gas to domestic and industrial use. Several members of this District Association have attended some of the lectures, and will bear out the large enthusiastic attendances, the great interest taken, and the knowledge gained.

In this preamble it has been my desire to indicate that the fullest possible use of showrooms and propaganda sales work cannot be made unless the outdoor staffs have had good opportunities of learning of the application of the commodities provided by their respective undertakings. It will be found that acquired wider knowledge arouses in them enthusiasm and strong belief in the industry they serve.

Essentially the uses of gas are of primary importance, and should be at the fingers' ends of every member who has to meet the consumer in any capacity. There is, however, another side, products—*viz.*, coke, sulphate, &c. Examine the published balance-sheets of any undertaking. It will be noted that the revenue from coke takes a very important place; but does it show the figure we should like to see? The answer is in the negative.

Coke has very wrongly been considered a "Cinderella" among fuels. Why? Because we have not given it the attention it deserves or the publicity it warrants. Generally speaking, it has been sold in its raw state. The charges against the sales of the gas itself are very heavy, but coke, the ideal smokeless fuel, when properly prepared, has received in the past but scant attention. The charges against it are very small, and chiefly confined to the costs of loading; nothing, or practically nothing, being chargeable to its preparation or development. And then wonder is expressed at the position to-day!

Manufacture the best coke possible by selected and blended coals, and then give it publicity in the offices and showrooms. Let every consumer who comes in, whatever his business, see an exhibition of clean, good coke, in graded sizes for all applications, put up in attractive form, with proper literature as to its uses ready to hand. It will then begin to sell itself. Stress, however, must be laid on its exhibited appearance—the samples should be clean, well housed, and attractive to the eye. This method will do much to popularize, and further the uses of, coke for domestic and other work; and if carefully handled, it will compete with, and largely take the place of, anthracite in closed stoves and water-heating apparatus. It is astonishing how effectual is this form of publicity; but the showroom staffs must be in possession of correct knowledge regarding the suitability and uses of the different graded sizes, and be able to advise the consumer intelligently.

For the past year we have made this a point in our lectures, and have utilized our five showrooms and offices to exhibit the graded sizes as effectively as possible. From our experience, this publicity has been eminently successful in popularizing and stimulating the local sales of coke for many divergent purposes.

Since adopting this policy, we have taken a large number of orders in the showrooms, by reason of the publicity given to coke. Fig. 1 indicates an all-coke window at one of our offices, showing the fuels, methods of use, and appliances, both domestic and industrial.

Experience has already shown that local sales can be largely stimulated, and that the showrooms can enormously assist the sales of coke, and tend to put this valuable fuel and asset in a much higher and firmer position. The same may be said of the co-operation of the showrooms in giving publicity to the

FIG. 1.—AN ALL-COKE WINDOW.

sales and uses of sulphate; but the staff must have some intelligent knowledge of the subject. Recently my Company offered neutral dry sulphate in 7-lb. linen bags, with the instructions for use printed on the back. Prominence was given to the product in all showrooms; and the result was gratifying. In a few weeks over 1500 individual sales were made, in addition to many inquiries. Publicity brought this valuable fertilizer to the eye of the public; and they purchased heavily locally. The prominence given has also brought us inquiries for small quantities of one and two ton lots from small-holders many miles away. In addition there were, in that period, a large number of inquiries for information and literature, which will probably mature. In the town and surrounding districts, amateur gardeners, farmers, and others have awakened to the fact that gas companies make this splendid fertilizer; and the goodwill of our business can also enter into their gardening pursuits, if the showrooms make it possible. There is a still wider local field for this commodity in the form of lawn sand, which will find a ready sale in most of the towns and districts where there are large numbers of small grass lawns to the residences.

In moving among even educated people, it is appalling to find the ignorance displayed in conversation relative to the great services the industry renders to the country and in the homestead. The extravagant views held by the unthinking public (they have never mentally advanced beyond the lighting stage) regarding the expected uses and ultimate powers of electrical energy, would make even the most hardened electrical salesman blush. Propaganda by newspaper advertisement is good, but publicity in the offices and showrooms is better, more persistent, and lasting. Slowly but surely the public are realizing that our sister industry has a relative and wonderful position in the world, but also that the gas industry is filling an important place in our national and home life which no method of electrical application can ever hope to displace without leading to national danger and disaster.

Conservation of coal, the constructive distillation of coal for products for national requirements, heating, agriculture, road-making, and also defence—and, more important still, the 80 p.ct. thermal efficiency figure of the gas industry's method of coal usage—should be given the utmost publicity at all times in every office at which a gas consumer calls. Fig. 3 illustrates a case—we have one in each office and showroom—by which we keep this important fact before the public eye. Residual products of our industry's processes of constructive distillation of coal are exhibited.

FIG. 2.—SHOWROOM PUBLICITY.

Fig. 3.—A Show-Case of Gas Products.

Remember that in propaganda work you must keep on telling and hammering-in the facts until the public get an opinion firmly established in their minds. The British public have not yet realized that electric energy production yields at its best practice only 19 p.ct. of the total energy of the original coal used, with no residuals except ashes, and that normally only 10 p.ct. of the total useful heat of the coal is available for the use of the consumer. The truth regarding national coal conservation should receive its meed of publicity by showroom propaganda.

Then again, there is the work of public education regarding the matter of smoke abatement. The offices and showrooms can exert a powerful influence in forming public opinion on this important matter; and I think this is a subject in which the gas industry plays the leading part. The public have not yet mentally visualized this fact and the important value of increased sunshine, though, by the tremendous appreciation and the growing uses of gas and coke, it is evident there is an awakening in this direction, if partly with the object of solving some of the domestic problems. There is a direct relationship between smokeless towns and individual health; and the public will awaken to this fact if we give them the opportunity to learn, by persistent propaganda in our offices and showrooms, aided by intelligent advertising work. Fig. 4 shows an interested crowd at our Queen Street Office—a crowd indicative of several weeks' interest in our special line of propaganda work.

The interpretation is, therefore: Make your showrooms miniature Wembley gas shows, and, as the Americans say, "tell the world" the manifold services that the gas industry can render to the nation in the conservation of our coal, and the application of gas to domestic, industrial, gardening, agricultural, and road-making pursuits, and also the many other directions wherein we can render service, in the best possible sense of the word, to the public we serve.

Fig. 4.—Outside the Queen Street Office, Cardiff.

The salesman in the office must be trained to be the "Fidus Achates" of the consumer in every possible direction; and the showrooms and offices, coupled with the intelligent knowledge and equipment of the salesmen—a knowledge which the industry itself can and must provide—are a great asset to this end. Some may say this policy is only possible for large undertakings. I state definitely that publicity and propaganda for the sales of gas and products are possible for, and equally vital to the best interests and advancement of, any undertaking, be it small, large, or medium in size. Individual undertakings should draw upon such organizations as the British Commercial Gas Association, the National Gas Council, and the British Sulphate of Ammonia Federation, for the help, guidance, and assistance which they may require in the furtherance of their sales. Though these organizations do magnificent work, and are basic resources, they cannot be expected to do the detail work of local publicity and propaganda, which must necessarily fall to the lot of the individual undertaking. All should co-operate in local publicity.

Discussion.

The PRESIDENT (Mr. W. H. Johns, of Swansea) said the paper had been very interesting, and offered ample scope for discussion by managers of works of all sizes.

Mr. J. H. CANNING (Newport) said Mr. Madden had again made them his debtor by a paper, the chief merit of which was that the "preacher practised what he preached." There was nothing the author recommended to them for their consideration which he had not put into effect very successfully at Cardiff. He had fairly exhaustively gone over the whole question of general sales propaganda as regards gas, coke, and other residuals; and it would be impossible, to deal with the paper in detail. He would like, however, to pick out one or two salient points, as matter for emphasis rather than discussion. The importance had been stressed of providing the most attractive showrooms for the display of fittings; and his (the speaker's) own experience backed this up. The more attractive they could make the window, the better would be the results. It was found at Newport that, when they could arrange a "live" or moving exhibit, it had a more pronounced effect than anything else in attracting the public. The paper really, he thought, might be summed-up in one brief sentence—the education of the public and the education of the staff. Upon these two points depended the success or otherwise of the undertaking. The author very rightly said that the general public, though they had been using gas for something like a century, were profoundly ignorant of its modern developments, and were consequently rather apt to be taken by the electricity propaganda. Gas people should not hesitate to keep on drumming into the public the many good points of gas, because no success in advertising could be obtained without constant repetition and perseverance. These were the great elements of success in advertising. The author had given them excellent advice with regard to the sale of coke; and the success that had been attained at Cardiff in this respect had been most gratifying. It seemed to him that they could all to a large extent, by following the advice given, promote their coke sales. By grading the coke, and by making the public aware of its vast possibilities, they could sell a great deal more of it in their districts than they were doing at the present time.

LOCAL EXHIBITIONS.

With regard to propaganda and advertising, there was one matter which Mr. Madden had not specifically included, and that was local exhibitions. At Newport much benefit had been derived from taking part in the travelling exhibitions which came along from time to time, and sometimes arranging purely gas exhibitions. Certainly this had had the effect of promoting sales. It was true that on several occasions their electrical competitors had exhibited under the same roof; but this was all to the good. Where the public had an opportunity of comparing the services rendered by both industries, gas people need have no fear whatever of the ultimate result. Some of them had been present a few days previously at the opening of a very interesting exhibition promoted by Mr. Jackson at Neath; and this, he was glad to learn, was giving excellent returns, in good attendances and large sales.

POLITICAL PROPAGANDA.

At the present time they had to face a particularly powerful phase of what one might call political propaganda in favour of their competitors. He did not think there was any need to go into this in detail. They all knew quite well what not only this Government, but two others he believed (all the political parties, in fact), had put forward as being a remedy for some of the existing social ills—namely, the granting of an enormous subsidy to their competitors, on the plea that the supply of cheap electrical energy all over the country would bring about a restoration of trade. He ventured to assert emphatically that no development of the electrical resources of this country would ever secure such a result, and that the present depression in trade arose from deeper-seated causes which were well known to those in power; but to put it plainly, they had not got the honesty to tell the public what these causes were. Unfortunately, to-day they had very few Statesmen and very many politicians; and there was a vast difference between the two. One of the chief arguments in favour of the development of cheap electricity in this country was that other people had developed their electrical resources, and consequently this country should do so. The truth was that, in general, electricity had only been widely developed in countries where considerable water power was available and at the same time coal was dear. In this country there was not the water power available, and coal was comparatively cheap; so that the conditions were quite different. One could well imagine that, in a country where

coal cost anything from £3 to £5 a ton, and water power was at hand, considerable economy could be effected by electrification; but in this country, where the only source of electrical energy was coal, and taking into account the fact that electricity yielded at best less than 20 p.ct. of the total energy of the coal, how could electric power show any economy as compared with the present use of raw coal? It might be said that electricity had not been given a chance; but it had been tried in this country. It had been pointed out by Mr. R. G. Clarry, in a very able speech in the House of Commons a few days previously, that the North-East Coast was supplied now with electricity at a price which would compare with the cheapest supply in any other part; and yet the industries were even more depressed, if possible, there than elsewhere. But it was not necessary to go to the North-East Coast for an example. Those who had gone over the great Ebbw Vale Works would have noticed that they were obtaining electricity from blast-furnace gases for practically nothing; and the same thing applied to the Powell-Duffryn concern, where they were producing from coke-oven gases electricity at quite a nominal figure, after deducting the value of the residuals. Yet, unhappily, these two undertakings were suffering from depression as much as the others. Therefore, he asserted that it had in no way been proved that electricity was going to be the panacea for industrial ills people were endeavouring to make out. Some of the greatest electricians objected very much to the exploitation of their industry by politicians. Pushing electrification could not bring about the abolition of smoke. Of course, in many cases electric power could be substituted for steam; but it must be remembered that steam was used in many industries for other purposes than power—purposes for which it was essential. Again, there were thousands, or even millions, of furnaces in this country used for metallurgical processes; and never would electricity be able to carry out the work done by these. With regard to boilers required for steam generation only, and metallurgical furnaces, gaseous fuel was the sole solution. As for cheap electricity solving the domestic smoke problem, this was even more hopeless. Some years ago the great Dominion of Canada, possessing almost unlimited water power, went into this matter, and they did so in a scientific manner. The whole subject was submitted to the Honorary Advisory Council for Scientific and Industrial Research at Ottawa; and their report, which might be consulted by anybody, pointed out that the entire power of Niagara was insufficient to heat the one city of Toronto. He might quote from the report these few words: "It is therefore hard to conceive of a time when electric energy will compete successfully and on a large scale with coal, oil, gas, &c., for heating." Then it was claimed that it would be an advantage to electrify the railways of this country. It was quite true that in Italy, with large water power resources, it had been practically necessary to electrify railways; but in this country there would be no economy whatever in doing so. Up to the present he did not think that a single responsible railway engineer had looked kindly upon the project, except in special cases and for short distances.

THE TRUTH ABOUT GAS.

As against all this, the gas industry had many advantages to offer. Instead of the less than 20 p.ct. of the heat energy in coal which the electrical people obtained, the gas-works recovered, in a form available for the use of the public, something in the neighbourhood of 80 p.ct. of the heat value contained in the original coal, and, in addition, immensely valuable residual products. They all knew the gas industry was not going to decay; but supposing the country was so misguided as to permit it to do so, all the essential things derived from these residual products would have to be imported by the various industries dependent upon them, who would probably have to "pay through the nose" for what they required. This was a position which could only be contemplated with the utmost disquietude. Mr. Madden had referred to the question of national defence; and in this connection it was remarkable to find that the public, just as they had already forgotten to a great extent the men who went to the front and fought for them, had also forgotten the industry which came forward at a time of national emergency to the support of the country. He did not wish to stress the matter unduly; but they would remember the following words of the late Lord Moulton: "Without the direct aid of the gas industry and the assistance of the knowledge which had been acquired by those who had devoted their lives to it, it would have been perfectly impossible for this country to wage the campaigns of the last three years, or even for any but a trifling time to resist the overwhelming flood of enemies that was poured upon it." In conclusion, he thought that the gas industry neither wanted a subsidy for itself, nor did it want to see a subsidy given to its competitors. The electrical industry was not in such a parlous condition that it could not secure money for its own development; and if the Government would only give both industries a chance, there would be nothing to complain of. The gas industry had no wish to belittle the immense service electricity could render in certain fields; but there were also other fields in which gas was infinitely superior. If the Government would just allow the two to compete with one another, without subsidizing either, it would be to the public good; and both would be able to develop their respective fields for the benefit of the country and its inhabitants.

Mr. W. CLARK JACKSON (Neath) remarked that the paper was very timely, because gas engineers even now were apt to consider their works first, second, and sometimes third; whereas they should at all times remember there were the consumers to be attended to. It was only by persevering in the education of the public that they could hope to develop the industry as it ought to be developed. Sustained publicity was essential; it must not be taken up, put aside for a time, and then taken up again. Unfortunately, many of them had difficulty in persuading boards of directors or members of councils as to the absolute need for the provision of adequate showrooms. He had himself laboured this point with his Council for a number of years. He had a small showroom which had done remarkably good work considering its size; but it was not sufficient for its purpose. Reference had been made by Mr. Canning to the exhibition at Neath. This was a great success, and the cookery lectures evoked much interest. They must strive all the time to get to the public. They knew themselves what could be done with gas, but the general public did not know. The photographs accompanying the paper would be particularly useful to the members.

Mr. A. E. DAVEY (Aberdare) referred to statements which had been made regarding the possibilities of low-temperature carbonization in this connection. He said it seemed to him that the great aim of people fostering these electrical schemes was to connect them with low-temperature carbonization.

Mr. R. J. AUCKLAND (Cardiff) thought the great value of Mr. Madden's paper was in its particularization. They had the "B.C.G.A.," who advertised in a general way, and in a manner which individual undertakings would find it impossible to do, for the good of the whole industry. But each undertaking could derive further benefit by particularization of the wares it had to put before the public. What was needed was to press home particular points in particular directions; and Mr. Madden had shown how this might be done with respect to residual products. Very large success had been achieved by him at Cardiff in this way; and other undertakings would similarly benefit by organizing specialized campaigns in certain directions.

THE SALESMEN'S CIRCLE

Mr. B. J. BELL (Cardiff) said he would like to take the opportunity, as Secretary to the local Salesmen's Circle, of appealing for stronger support. Of late the Circle had not been getting from the district the support to which it was entitled. If the efficiency of the undertakings depended upon the education of their staffs such meetings should have the fullest support. He hoped everything possible would be done to augment the attendances, so that such discussions as took place might be to the benefit of all concerned. It was of the utmost importance that there should be a better balance of attendance from the various undertakings, if the Circle was to be of the greatest possible value.

Mr. J. PROSSER JONES (Caerphilly) pointed out that, in addition to showrooms, publicity could also be advanced by means of literature. The showroom was very nice to look at, but many people would pass it by. What he did, in addition to showroom work, was to put a little advertisement on every gas bill sent out; and this advertisement was altered each quarter. This brought to the notice of consumers apparatus which perhaps they had not heard of before. Showrooms were, of course, essential; but they must be accompanied by propaganda in the form of literature.

The PRESIDENT proposed a hearty vote of thanks to the author, and said it was very important that all connected with gas undertakings in that area should do everything they could to cultivate sales of residuals in their own districts, instead of sending them outside. By so doing, they would assist in maintaining prices at reasonable level, with resultant benefit to the whole of the undertakings in South Wales. If they would take the trouble to send coke round the town in small lots by motor van, as had been done in certain cases, it would probably meet with success. They all realized that there was a very great future for gas; and, notwithstanding all that had been said about the development of electricity in Canada and other places, he had been given to understand that there was a progressive gas undertaking at the very foot of Niagara. If gas could meet competition at a place like Niagara, where power was practically free, it should be an incentive to the industry in this country, where things were different, to "put its back into it." He believed Porthcawl and Port Talbot were now entering into schemes for the provision of electricity. If the gas undertakings still maintained propaganda work, he did not think they would find that the introduction of electricity would affect them very much; but it was essential that the work done by the gas undertaking should be prominently put before the public, not once or twice a year, but practically daily.

HOUSE-TO-HOUSE CANVASSING.

He found in Swansea, at any rate, that the house-to-house canvasser was as good an advertiser as anyone, provided he knew his job. If he could get an interview with the housewife, more orders could be got in this way than in any other. At a recent exhibition in Swansea the Gas Company secured the largest number of votes of any exhibit. They must not forget the fact that it was not considered by some of the leading electrical engineers of the day to be a paying proposition to erect super-stations and distribute electricity therefrom over long distances.

The HON. SECRETARY seconded the vote of thanks, and drew attention to the fact that he had a collection of slides and a lecture on "Gas Manufacture," which anyone could have the loan of on applying to him.

THE AUTHOR'S REPLY.

Mr. MADDEN said it was always a pleasure to him to prepare a paper for the Institution. It was true that the "B.C.G.A." carried on the general propaganda; but each particular undertaking must be responsible for the details. This was the great point he wished to bring out. Literature and house-to-house canvassing were invaluable. In Cardiff they made tremendous use of literature; and much business accrued there from house-to-house canvassing. The output of fires and cookers, due to propaganda and publicity, was nearly three times as much as was the case before. He wished to pay a tribute to Mr. Bell, his District Superintendent, who worked so hard to make the Queen Street window a live one, that it won three prizes in Cardiff Shopping Week. The Company had shown industrial appliances, &c., at the local Engineering Exhibition, and had been astonished at the amount of interest taken in their stand. At agricultural shows, and such like, they had a marquee, and showed sulphate, and crops grown on sulphate. The Sulphate of Ammonia Federation came handsomely to their aid with literature in this connection. They also got the farmer interested in graded coke, and prepared tar for painting out-houses. The matter of low-temperature carbonization was one they must not allow to slip out of their hands. If there was any desire for low-temperature carbonization fuel—and there might be—the proper place to make it was at the gas-works, where they had nine-tenths of the plant that ac-

counted for the capital cost of low-temperature carbonization. Those who had been privileged to hear the able address of Mr. Milne Watson at the annual meeting of the National Gas Council felt that the case for the gas industry was in the best possible hands. ["Hear, hear."] But they must all get in a body behind him, to help him at every time and in every place. The most loyal support throughout was essential.

WALES AND MONMOUTHSHIRE JUNIOR GAS ASSOCIATION.

Treforest Low-Temperature Carbonization Plant.

At the invitation of Mr. D. Muir, M.I.Mun.E., Engineer and Manager of the Pontypridd Gas Department, the members of the Wales and Monmouthshire Junior Gas Association visited the low-temperature carbonization plant at the Treforest Gas-Works, on Saturday, May 23. Dr. S. R. Illingworth conducted the members over the plant and explained the various processes, following which an adjournment was made to the Municipal Buildings for a meeting, at which the President, Mr. B. J. BELL, took the chair, being supported by Mr. D. Muir, Dr. S. R. Illingworth, and Mr. King-Hiller.

The minutes of the previous meeting were confirmed; and the PRESIDENT extended a welcome to Mr. King-Hiller. He remarked that the Association had again been favoured by the opportunity afforded the members of observing the new plant at the Treforest Gas-Works, which was of much interest, particularly to those engaged on the manufacturing side of the industry.

Dr. S. R. ILLINGWORTH then delivered the following

ADDRESS.

I was invited by Mr. Muir to speak to you on low-temperature carbonization. We are all aware that the carbonization of coal is passing through a transition stage, due to the economic conditions under which we now labour. The carbonization of coal produces three main forms of fuel—viz., solid, liquid, and gaseous. Each type varies within limits. In regard to coke, we can ring the changes from a product of extreme hardness and limited combustibility, down to coke produced at the lower temperatures. The carbonizing works of the future, and the gas-works in particular, must, as Dr. E. W. Smith points out, become more and more a fuel works, supplying solid, liquid, and gaseous fuel of a type to meet local demand. Low-temperature carbonization of coal is one means of treating coal, producing certain products peculiar to itself; and only so long as these peculiarities are of economic value in competition with other methods, has it a place in practical politics. I make these remarks in the hope that you appreciate that there is, or should be, no antagonism between any of the several phases of coal carbonization. Low temperature has failed in the past to win a place in the sun, due to three specific reasons:

(1) The fuel has lacked a robust nature.
(2) The swelling of the coal in the process of carbonization has retarded or inhibited facile discharge from the retorts.
(3) Due in the main to the slow transference of heat throughout the charge at low temperatures, carbonization in bulk has not been a feasible proposition. Narrow-section retorts have been employed, and the consequent small capacity has resulted in high labour costs and concurrent high capitalization on the output.

Defects (1) and (2) are closely related, both as to cause and remedies. In 1909 I had recourse to the blending of caking and non-caking coals in connection with certain work in carbonization at low temperatures. More recently, as the result of purely academic work on certain coking coals commenced in 1918, the cause of the swelling of the coals became evident to me. Blending of coals, and also a process of pre-heating a bituminous coal alone, were worked, to avoid swelling and to produce contraction. Briefly, we can say that a bituminous coal commences to form coke at temperatures from 400° to 550° C. The temperature is a function of the carbon-hydrogen ratio; those coals of higher carbon-hydrogen ratio having the higher initial temperature of coke formation. The initial formation of coke is the more intimately concerned with the decomposition of the γ component—*i.e.*, that portion of a coal ultimately soluble in pyridine, and also in chloroform and benzene. Whether or not this be a primary constituent of coal, we will not discuss on this occasion. The γ compound is of a resin-like nature. It melts, conferring plasticity on the coal mass, at a temperature slightly below that of decomposition. All types of γ compound are decomposed as such at or below 450° C. Thus the initial formation of coke is completed below this temperature, which becomes some 100° higher on a practical scale, in order that the necessary temperature gradient exists within the charge. There exists within the coals a further series of components, referred to as the β type. These are of cellulosic nature. Their chief characteristic for the moment is the fact that they decompose at lower temperatures than the γ. The result is that the coal in the plastic state is distended by the volatile matter evolved from these β compounds, the action of which is analogous to the yeast in dough. Since these β compounds are the main cause of the swelling of the bituminous coals, and, further, since they are decomposed at lower temperatures than the γ compounds, it becomes possible to eliminate them from the coal at a temperature sufficiently low to avoid serious decomposition of the cementing material—*i.e.*, to avoid a coherent mass and serious impairment of the cementing power of the coal. This preliminary treatment of the coal is completed at an economic rate at temperatures in general around 400° C. The waste heat from the carbonization proper is of sufficient intensity and amount to accomplish this end. Consequently the pre-heating operation is analogous in function to an economizer on a boiler.

Coals in general evolve their volatile matter within two characteristic temperature ranges. One of these is below 500° C., the other is in the region of 760° C. I have referred to these as nodal points. The lower nodal point (*i.e.*, the one below 500° C.) varies with the carbon-hydrogen ratio of the coal. The higher nodal point is practically constant in all coals. The lower nodal point is around 275° C. for the lignite type of coals with a volatile about 45 p.ct., and the temperature at which it occurs increases with decrease of the volatile of the coal, until in the case of the anthracites (volatile under 6 p.ct.) it has ceased to exist. Now two facts operate in the swelling of coal: (1) The occurrence of a plastic state; (2) the amount of volatile matter evolved within the plastic layers of the coal when such plastic layers are undergoing decomposition. The persistence of the plastic layer is a question of the amount of γ component. The volatile evolved within this layer is a matter of the substances which undergo decomposition at or below temperatures at which the characteristic γ decomposes. You will appreciate that, if a coal with a very low nodal point (say, around 300° C.) be admixed with a caking coal, the plastic layers of which persist at 400° to 450° C., then the volatile from those substances which contribute to the nodal point at 300° C. will have been evolved from the coal prior to decomposition of the plastic layer, and will hence exert no distending influence on the coal. Moreover, the γ compound will have become diluted with the residue from the less stable coal, and hence the distending influence due to subsequent evolution of its own volatile will be minimized. It so happens that the coals poor in quantity and in quality of cementing material—*i.e.*, the non-caking or weakly-caking coals—are either possessed of a nodal point which occurs at a low temperature, or else, if they be non-caking coals such as the dry steams and anthracites of South Wales, they are possessed of no nodal point at all. We are thus able, from a knowledge of the nature of the gamut of coals, either to blend them or, in the case of bituminous coals, to preheat them so that the final product for carbonization has a specified nature in regard to γ content and the volatile matter evolved at temperatures below 500° C. Briefly, the general salient feature is that the γ content must not fall below 5 p.ct., and should not exceed 10 p.ct. Coal in this condition does not expand on carbonization, but contracts. While thus facilitating discharge from the retorts, it also gives a carbonized product of greater density and hardness.

I have touched on these points. They are not specific to low temperature alone, but appertain to all phases of carbonization. It is of interest to note that the highly-prized gas coals, such as those of South Yorkshire, are possessed of the specific features enumerated above as conditional to the non-swelling of the carbonized product. It is appreciated that other investigators have addressed themselves to these problems.

The third inherent drawback to low temperature has been attacked along a number of lines, which may be enumerated as follows:

(1) The method of the internal heating of the coal while the charge is at rest—*e.g.*, the Maclaurin method, whereby producer gas generated in the lower part of the retort heats the overlying charge by virtue of sensible heat carried upward by the gas. In this case fine coal such as duff cannot be used without briquetting. Moreover, the gas evolved is of a low calorific value.

(2) Internal heating with agitation of the charge—*e.g.*, the Nielsen process, wherein the charge is in a rotary retort through which hot gases are passed. The rotation tends to produce breeze.

(3) Briquetting of the charge—
(*a*) by pressure—*e.g.*, Sutcliffe process;
(*b*) by pressure *plus* heating of the coal—*e.g.*, Fuel Research method, &c.;
(*c*) by pressure and binder—*e.g.*, Fisher.

(4) Briquetting *plus* internal heating, or briquetting and heating the retort externally. The briquetted fuel is carbonized more rapidly than in the mass, due to the large free space for the gases evolved or introduced into the retort.

(5) Use of special forms of cast-iron retort.

(6) Heating in thin layers, as in the lead bath process of Caracristi.

Preliminary operations prior to actual carbonization naturally increase the total cost of production. These costs have to be offset on balance by such factors as greater throughput per capital unit of retort, increased yields of products, enhanced value of products, &c. These factors can only be assessed by actual works operations and tests against market conditions,

guided, of course, by previous experience as to renewals, maintenance, &c., in cognate procedure now in operation.

Briefly, then, from the modern trend of low-temperature carbonization, or in more general terms the carbonization of coal to produce a more mobile range of products to meet requirements for smokeless fuel and a desire for liquid fuel, the operations we have to visualize are:

(*a*) Preliminary treatment—viz., one or more of the processes of blending, preheating, drying, and briquetting.
(*b*) Charging operations in retorting.
(*c*) Retorting.
(*d*) Discharging and cooling of fuel.
(*e*) Condensing and recovery of bye-products.

Mr. Nielsen recently stated that the capitalization per ton for low-temperature retorts must not exceed about 10s.; and in this connection I take it to mean 10s. per ton capacity, with no additional cost for rendering the product marketable. With this view I agree.

We have endeavoured to bear in mind the general points outlined above in designing the plant you have seen this afternoon. We have arrived at this stage by three steps: (*a*) The laboratory stage, mainly concerned with the fundamental characteristics of the gamut of coal, and the influence of such on the behaviour of coals when carbonized. (*b*) The experimental stage, which aimed at testing our theories on a semi-commercial scale, and subsequently arriving at an economic design of plant to make them successful commercially. This we carried out at our experimental station alongside the Maritime Coke Ovens, from whom we drew our gas supply. We received every courtesy from their Manager, Mr. T. Watts, B.Sc. (*c*) The commercial scale. Our first commercial unit, as you have seen this afternoon, is erected at the Gas-Works, Treforest. You will note that we have refitted a bed of the intermittent vertical retorts, initially installed there by Messrs. Robt. Dempster & Sons, Ltd., of Elland. Messrs. Dempsters carried out this scheme for us, and we have received every assistance from their Managing Director, Mr. Broadhead, and Mr. Toogood and his staff. It is not my purpose here to describe all details of the plant. You have seen it in operation; and when we refit the whole installation of these intermittent verticals, the contract for which has been placed, it is our intention to invite the Wales and Monmouthshire District Institution of Gas Engineers and Managers to inspect the plant.

We are using a brickwork retort, and the heat is taken into the charge by H-section conductors made of cast iron. Each conductor is independent and is under no stress. Further, any one conductor is easily removed. Our ovens at Pontypridd are 9 ft. 6 in. long; and since, due to these conductors, we carbonize in five to five-and-a-half hours, our output per oven in the 24 hours is practically 7 tons. It may be of interest to remark that a brickwork oven without conductors, and of the width (14 in.) we use, normally takes some 28 hours to carbonize at corresponding temperatures. In these circumstances the fuel is over-carbonized at the oven walls, and under-carbonized in the centre. The fuel we make is homogeneous throughout, and the volatile is from 5 to 6 p.ct. The retorts are heated either by producer gas or by gas from the process. We have utilized the same charging gear as formerly employed for the bed when working for ordinary gas-works practice, and our labour costs are correspondingly low. Discharge from the retorts is facile, since, by blending or preheating, we guarantee shrinkage of the fuel. You will notice that the coal passes in continuous cycle from the siding, through the retorts, thence as smokeless fuel to wagons.

The yields of products we obtain are of normal nature. All types of coal can be used, provided one is bituminous. The lower the volatile, the greater the fuel yield, but the lower the gas and the oil yields. Broadly speaking, from the Welsh steam type of coals—volatile (say) under 20 p.ct.—we obtain 83 p.ct. of fuel, some 6 to 8 gallons of oil, and about 3500 c.ft. of gas (B.Th.U., unscrubbed, 750). With the higher volatile coals such as are used in the gas industry we obtain about 70 p.ct. of fuel, some 18 gallons of oil, and 5500 c.ft. of gas. One point in connection with the gas yield might be mentioned. The low-temperature gas yield is approximately 40 therms per ton from the higher-volatile coals, as against 80 therms from the high-temperature treatment. We have established that, on the same floor space and within the same cubic capacity as that previously taken for a ten-ton per day throughput of coal at high temperatures, we are obtaining twice the throughput of coal at low temperatures. Consequently the gaseous therm yield is roughly the same per 24 hours; but, of course, twice the weight of coal has to be handled. The therms are too "concentrated," and will need diluting with a weaker gas for distribution. If, however, gas has to be transmitted far—say, under a system of high-pressure distribution—such gas might be more economical, since, per cross-section of pipe, the therms transmitted would be greater. Maybe in future we shall centralize gas production at larger works, and distribute to substations.

In addition to this we can scrub (from the gas) some 2½ gallons of light hydrocarbons, benzoles admixed with naphthenes, suitable for motor purposes. We have not installed a benzole recovery plant at this stage, but we shall do so on the larger basis.

Ammonium sulphate is a problematical asset. True, due to drying the coal, we have an 8 to 10 oz. liquor, but I fear that in the future synthetic ammonia may render the recovery of ammonium sulphate from the liquor unremunerative.

The tendency in the past has been to concentrate attention on one or other of the chief products derived from coal, and regard this as the dividend asset. Nowadays we are regarding all the products from a basis of greater relative importance. Mobility of procedure is the desideratum. The solid form of fuel produced by low-temperature carbonization has a far greater market mobility than ordinary coke in its present form. The product we market is used as a domestic fuel in the open fire and kitchen range, for central heating, in bakers' ovens, for steam raising, and in anthracite stoves. Independent steam trials show that the fuel is equal to South Wales best steam coals. Low-temperature processes thus offer a means of satisfying the solid, liquid, and gaseous demands. The crux of the matter is that the local demand for solid fuel in competition with coal and coke will be such that the straight gas from the carbonization, when diluted with water gas, will furnish not less than the amount of gaseous therms required by the region in which the solid fuel is marketed. This visualizes nothing but a low-temperature process as the source of gas. One sees no reason why the two processes of high and low temperature should not work side by side, each finding its own level. If the demand be for low-temperature products, then this process will become established, if production and capital costs are within economic range. Low temperature enables a wide choice of raw material at a cheap rate in the form of all classes of small coal.

Discussion.

Mr. T. A. CANNING (Newport), in proposing a very hearty vote of thanks to Dr. Illingworth for his address, said he would like to have some further information in regard to the relative economies of preheating and blending coals, the maximum permissible ash content of the coal used, and the nature of the residue left by the fuel when consumed for domestic purposes. In regard to the figures put forward by Dr. Illingworth, the rate of depreciation was certainly liberal. Mr. Canning said that the future of the industry rested not only on gas sales, but also on the profitable disposal of their bye-products.

Mr. V. T. BLAKE (Cardiff) seconded the vote.

The PRESIDENT cordially supported the vote of thanks. The primary duty of a gas undertaking was to provide gaseous fuel in a form suitable for use in its district. Recently some anxiety had been occasioned many undertakings in disposing of solid fuel; but at Cardiff they had met the situation by grading. Dr. Illingworth had said that super gas-works might be created. It had been observed, however, that the distribution of gas beyond 20 miles was likely to prove more costly than the freightage of solid fuel and its carbonization at local gas-works. Assuming that cheap solid fuel was being produced capable of being utilized under all conditions, and at the same time a cheap gas was being made, what would be the effect one upon the other? With regard to the coal carbonized, would the reduction of 10s. per ton in price compensate for the loss of output in gaseous fuel? In his opinion there was a market for smokeless fuel.

Dr. ILLINGWORTH said the question of pre-heating or blending was largely determined by local conditions and the price paid for coal. With regard to the ash content of coal, under existing conditions one had to be satisfied with a maximum of 7 or 8 p.ct. No cinders whatever remained after the use of the solid fuel.

The PRESIDENT, in calling upon Mr. D. Muir to deliver his address, remarked that no one had done more to promote the welfare of the Junior Gas Association than had their host of that day.

METHODS ADOPTED TO DEAL WITH LEAKAGE IN COLLIERY DISTRICTS.

By D. MUIR, of Pontypridd.

The question of unaccounted-for gas is one which constantly demands the attention of gas engineers, but more particularly those situated in mining areas, where subsidence is prevalent. In such areas, broken mains and drawn joints become at times a veritable nightmare. All unaccounted-for gas is not due to leakage, as it consists of losses incurred when connections are being made on the distribution system for the purpose of repairs or extensions, joints and mains leaking, defective meters, public lamps remaining lit after their scheduled time, and difference in temperature between the works and consumers' premises. Where gas is leaking on the distribution system, it is a dead loss to the undertaking, and a source of danger and a nuisance to the general public.

The points enumerated are to be found in any normal undertaking; but in mining areas, where there is a continual movement of the ground, the work entailed in repairing mains and joints is considerable. The Pontypridd area of supply, being situated in a mining area, is no exception; and I will give you briefly the methods adopted to reduce the quantity of unaccounted-for gas in Pontypridd.

In the first place, I had the station meter tested, and found this correct. The holders were then subjected to an examination, and any leakages repaired. This satisfied me that no leakage took place at the works. Then the consumers' meters on the district were tested and overhauled; and the result of

the tests showed the numbers of meters fast and slow were fifty-fifty.

Attention was then directed to public lighting. I found that, as a result of low-grade gas having been supplied due to war conditions, the burners had been rimered out, and were passing double the quantity of gas they originally passed. This, however, was not being charged for, and alone accounted for about 4 million c.ft. annually.

After this matter had been rectified, I turned my attention to the mains and services. In our worst areas I installed Thorpe's diagrammatic meters. These have proved beneficial, as the diagram on the meter shows the hourly rate of flow, and when the flow exceeds the normal it is a good indication of a break in the main.

From observations made when services were bare for inspection, I came to the conclusion that a large number of services were in a very bad condition. I have accordingly re-laid whole streets of services; and it was really a revelation to find the number of services which were absolutely riddled with holes.

In one section of our area, I found a considerable quantity of gas being lost on a 10-in. cast-iron main. I accordingly stripped every joint, and no less than 90 p.ct. required setting-up. These joints had drawn due to subsidence. After a lapse of two years, one particular section again showed signs of drawn joints; and I felt convinced that it would be useless to keep setting-up joints on this particular spot. I therefore decided to fix Dresser split clamps over the spigot and socket joints. These consist of two split clamps, one of which acts as an anchor behind the shoulder of the socket, while the other presses into position a rubber clamp gasket, which is faced with strong duck. These clamps fit the ordinary lead joint; care being taken that the lead joints are well set-up to leave a slight recess into which the gasket can be fixed. These clamps have proved satisfactory; and no further trouble has been given on this particular 10-in. main.

In the Pwllgwaun area of our district, weekly trouble was being experienced on a 6-in. cast-iron main, due to subsidence. Some idea of the subsidence taking place may be gathered from the fact that the Colliery Company are continually repairing the houses in this street. The 6-in. main was continually breaking, and drawn joints were the order of the day. At last the trouble was so acute that a gang of repairers were there every week. After careful consideration, I decided to re-lay this main with solid-drawn steel main with plain ends and Dresser steel pipe couplings. The 6-in. Dresser couplings consist of two pressed-steel flanges, two rubber packing rings or gasket, one steel middle ring, with centre bead for perfect centring, and six bolts and nuts. These couplings combine flexibility and strength, and allow for contraction and expansion, as well as ground-settling. The Dresser steel flange is pressed from solid plate, and is therefore an endless ring, with no weld to break or open-up. The thickness of the metal on a 6-in. Dresser coupling is approximately ¼ in.; and the length of the middle ring is 5 in. The 6-in. main in question has been laid for four months. Up to the present no leakage has been found on it, and I do not anticipate any.

Prior to deciding on Dresser couplings for this particular job, I carried out a test with an 8-in. coupling connecting-up two lengths of 8-in. steel main with blanked ends; the total length being over 70 ft. I then pumped gas into this main up to 50 lbs. pressure, and found same to stand-up absolutely tight. The supports were then knocked out below the coupling, allowing it to drop 2 ft. 3 in. in the centre of the pipeline, and no leakage took place. The pipeline was again brought back to the horizontal, and still remained tight. I also tried the joint up to 150 lbs. pressure, and it remained bottle-tight.

Where movement of the ground is continually taking place, it is customary to find either the joints drawn with subsidence or the mains fractured, due to squeeze set-up. I have found Dresser couplings to act in both cases, owing to the contraction and expansion allowed with them.

In certain parts of our district, the mains are being pushed their whole length towards the other side of the road. This results in services on one side being pulled out of the main, and on the other side being buckled-up. To overcome this, I have made the connections from the main to the service with two brass fittings connecting a stout piece of S-shaped lead pipe. A better method is by the use of pressure Dresser couplings. These consist of a piece of 1¼-in. steel tube drawn down and threaded to 1¼ in. to enter the main. The other end has a flange welded on; the tube protruding for 3 in. past this flange. This tube is again drawn down to allow a 1-in. pipe to pass inside. A flange and rubber gasket with two bolts complete the joint. In use, the pressure coupling is screwed into the main in the usual way, the 1-in. service pipe passed through the flange inside the tube, and then tightened-up. This allows the service to draw-out for a distance of nearly 3 ft. without leakage when the main is being pushed away, and, on the other hand, allows the service to travel in nearly 3 ft. when the main is being pushed towards the service. This method has proved very satisfactory, and has eliminated our trouble in cases of the position of the main shifting.

The methods briefly enumerated here have proved beneficial, and have brought the unaccounted-for gas figure down to the lowest point since 1908. Even in cases where subsidence is not prevalent, I believe trouble is often experienced with drawn joints nowadays, due to the much heavier road traffic setting-up vibration. Dresser couplings would be very suitable in such cases. From my experience with these couplings, I have adopted them in the laying of new mains; and I find that, owing to their great flexibility, it is possible to wipe-out a good number of specials on the work.

I trust that these few notes may be of interest to the members of the Association, as I am sure such difficulties as we experience in Pontypridd are common to a number of undertakings embraced in your field of activities.

Discussion.

Mr. KING-HILLER, on being asked to speak, said that Mr. Muir should be congratulated upon the fact of his being the first gas engineer in Britain to discover the utility of the Dresser joints. His (Mr. King-Hiller's) experience with the joint dated back to 1910, when he went out to Canada to investigate a natural gas proposition which resulted in the formation of a large company and the laying of 170 miles of 15-in. steel main on which Dresser couplings were employed. The main was completed in six months, and careful test disclosed only one slightly leaking joint. The gas issued from the well at a pressure of 850 lbs. per sq. in.—being governed-down to 250 lbs. per sq. in., and, passing along the mains at this pressure, supplied Calgary and towns *en route*. The pressure at the end of the main was 50 lbs., which was governed-down to the town distribution pressure of 5 in. The question of leakage on distribution systems largely resolved itself into one of jointing. Run-lead or lead-wool joints could not remain permanently gas-tight, owing to the effect upon them of temperature changes. He had recently had an opportunity of observing what he presumed was the effect of the heavy traffic on gas mains in some of the chief thoroughfares in London, which were being relaid, and numerous joints were being reset.

Mr. COLLINS (Swansea) asked whether the testing of meters was carried out *in situ*, or were the meters brought to the works? With regard to public lighting, the experience of Pontypridd was, he thought, fairly general throughout the country, as a result of war conditions, and he would like to know if the burners were changed, or simply the nipples. On the point of service inspection, what system was adopted to ensure that every service was right, and was going to remain right? The method adopted in carrying-out repairs on slit collars would be of great advantage to many. He thought the Dresser couplings admirable; but, of course, in normal areas they were not faced with subsidence to the same extent as in colliery districts. In Swansea they had trouble in one area; but this had been overcome by the laying of welded-steel mains.

Mr. J. WOOD (Pentre) said that in clamps of which he had experience the rubber had perished. What would the effect be with the Dresser coupling in the event of this happening?

Mr. WILLIAMS mentioned that at Abertillery subsidence had brought about compression, resulting in the end of the main being forced right through the other joint, and the pipe splitting.

Mr. CANNING (Newport) said they appreciated Mr. Muir's kindness to the Association, and his readiness to assist them at all times. In regard to the Dresser joints, he would like to have some information regarding the life of the rubber packing.

Mr. A. H. SHEPHERD (Swansea), on behalf of the Association, asked Mr. Muir to accept a very hearty vote of thanks for so ably assisting them, not only that afternoon, but at all times since the inception of the Association.

Mr. D. M. JOHN seconded the vote. Leakage, he said, was a most serious problem in colliery districts, and in addition meters gave a deal of trouble. He had experienced difficulty with certain makes of meters of a particular period, but was not aware whether this applied generally.

Mr. MUIR said he appreciated the kind remarks which had been made. Replying to the various points raised, he stated that the testing of meters was carried out *in situ*. The burners of the public lamps were of the old upright pattern; and he had taken the opportunity of discarding these, and having them replaced by inverted burners. With regard to the inspection of services, if, after duly attending to the mains in certain areas, leakage was still taking place, the services were tackled wholesale, as generally they were also found to be too small. In respect of the rubber joint, observation had been made on a joint which had been in use for a considerable number of years, and no deterioration had taken place. He had every confidence that the rubber would stand. In the case of compression on mains, the Dresser joints would be found of advantage.

Following the meeting, the members were entertained at tea.

Gas for Cooking Potato Chips.—It is learned from "Industrial Gas" that in the vicinity of Baltimore a distributor of potato chips has developed a considerable parcel-post business with merchants in the smaller towns, which has been made possible by means of an interesting method of preparation. Cooking potato chips so that they will retain their flavour depends, it has been discovered, almost entirely on the kind of fuel used for the purpose. Gas in connection with surface combustion cookers seems to have solved the problem. In the production of potato chips, one of the most essential points is that the oil in which they are cooked should be kept uniformly at a temperature of approximately 360° Fahr. Too low a temperature of the oil will cause them to absorb an excess of oil before being properly cooked. Too high an oil temperature results in the majority of the chips becoming too dark before the rest have attained the desired colour. Gas was finally adopted owing to the uniformly ideal conditions assured by its use as a fuel.

NATIONAL ILLUMINATION COMMITTEE OF GREAT BRITAIN.

Report for the Year 1924

From Mr. H. Buckley, Hon. Secretary, we recently received the following report for 1924 of Lieut.-Col. Kenelm Edgcumbe, the Chairman of the National Illumination Committee of Great Britain, which was presented at a meeting of the Committee on Jan. 29 last.

The work of the Committee during the past year has been principally concerned with business arising from the Sixth Session of the International Commission on Illumination, which was held at Geneva in July, 1924. In this connection the Sub-Committees on motor-car headlights and on symbols and nomenclature prepared reports for presentation at the meeting. As regards the former, the view put forward by the British delegates, that it would be premature to propose standardization at the moment, was adopted. The symbols proposed by the British Committee were adopted, and several recommendations of the Committee dealing with definitions were approved. The British Committee was represented by the Chairman (Lieut.-Col. K. Edgcumbe), Dr. Kerr, and Messrs. H. Buckley, W. T. Dunn, L. Gaster, C. C. Paterson, J. M. G. Frezise, J. W. T. Walsh, and R. Watson. Unfortunately Mr. Butterfield, Mr. J. G. Clark, and Mr. P. Good were prevented from attending. Representatives of France, Italy, Switzerland, the United States, and observers from Japan and Poland attended the meeting.

Reports of the meeting prepared by various members of the delegation have appeared in the technical periodicals [see "JOURNAL," Vol. 167, pp. 446, 642, 697; Vol. 169, pp. 150, 219, 349, 538, 606; *ante*, p. 467]. The following decisions were arrived at as a result of the meeting:

(1) The International Commission recommended for international adoption as the primary standard of light the brightness of a black body operated under conditions subject to accurate specification, and further recommended that the National Laboratories be asked to take steps:

(a) To formulate standard specifications for the construction and operation of the black body as a primary standard of light;

(b) To fix upon a definite figure for the brightness as a function of the temperature of such body, expressed in international candles per square centimetre.

(2) A Sub-Committee was appointed to draw-up a vocabulary dealing with illumination.

(3) The Commission provisionally recommended certain values for the visibility factor.

(4) The Sub-Committee on heterochromatic photometry was asked to include in its work the study of the properties of absorbent screens.

(5) A Sub-Committee was appointed for the study of colorimetry.

DEFINITIONS.

(6) The following definitions were adopted:

(a) *The Transmission Factor* of a body is the ratio of the flux transmitted by the body to the flux incident upon it.

(b) *The Absorption Factor* of a body is the ratio of the flux absorbed by the body to the flux incident upon it.

(c) *The Reflection Factor* of a body is the ratio of the flux reflected by the body to the flux incident upon it.

The flux reflected according to the laws of specular reflection is called specularly reflected flux, and the corresponding reflection factor is called the factor of specular reflection. The flux diffused—*i.e.*, that sent out in directions other than that of specular reflection—gives the diffuse reflection factor. The total reflection factor is obtained by considering the whole of the flux reflected by the body.

(d) *The Total Flux* of a source is the flux emitted by that source in all directions.

(e) *The Upper Hemispherical Flux* of a source is the flux emitted by that source above the horizontal plane passing through its centre.

(f) *The Lower Hemispherical Flux* of a source is the flux emitted by that source below the horizontal plane passing through its centre.

(g) *The Mean Spherical Intensity* of a source is the average value of the intensity of that source in all directions in space.

(h) *The Mean Upper Hemispherical Intensity* of a source is the average value of the intensity of that source in all directions above the horizontal plane passing through its centre.

(i) *The Mean Lower Hemispherical Intensity* of a source is the average value of the intensity of that source in all directions below the horizontal plane passing through its centre.

(j) *The Mean Horizontal Intensity* of a source is the average value of the intensity of that source in all directions in the horizontal plane passing through its centre.

(k) *The Reduction Factor of the Mean Spherical Intensity* of a source is the ratio of the mean spherical intensity to the mean horizontal intensity.

(l) *The Efficiency of a Source* is the ratio of the total luminous flux emitted to the total power consumed. In the case of an electric lamp it is expressed in lumens per watt. In the case of a source depending upon combustion it may be expressed in lumens per thermal unit per unit of time.

(m) *The Visibility Factor* for monochromatic radiation is the ratio of the luminous flux to the corresponding energy flux.

The relative visibility factor of a monochromatic radiation is the ratio of the visibility factor of that radiation to the maximum value of the visibility factor.

(n) *Brightness*. The brightness in a given direction of a surface emitting light is the quotient of the luminous intensity measured in that direction by the area of this surface projected on a plane perpendicular to the direction considered. The unit of brightness is the candle per unit area of surface.

NOTE.—The above definitions are translated from the official French text. The official English translation will be published later.

SYMBOLS.

(7) The following symbols were adopted:

Luminous flux . . .	F	Transmission ratios .	τ
Candle-power . . .	I	Absorption „ . .	α
Illumination	E	Reflection „ . .	ρ
Brightness	B	Visibility factor . . .	K

(8) It was decided that at the next session a meeting should be devoted to papers and discussion on the art of illumination and the furtherance of good lighting.

(9) It was decided that questions relating to street lighting should be considered at the next session, and the National Committees were asked to study the subject and to transmit their communications to the Central Office at the earliest date possible.

(10) The report submitted by the Chairman of the Advisory Committee on the lighting of factories and school buildings was recommended as a basis for regulations or recommendations on the lighting of factories and school buildings.

(11) The National Committees were asked to study the question of glare from motor-car headlights, and to send their communications to the Central Office in ample time for the next session.

The following Committees have now been appointed by the International Commission; the representatives of Great Britain thereon being shown in brackets:

Heterochromatic Photometry and Colour Screens—(Dr. E. H. RAYNER).
Definitions and Symbols—(Mr. J. W. T. WALSH).
Lighting of Factories and Schools—(Mr. L. GASTER).
Motor-Car Headlights—(Lieut.-Col. K. EDGCUMBE).
Colorimetry—(Mr. T. SMITH).

It was decided to reduce the annual contribution payable by each country in view of the probable increase in the number of constituent countries. Great Britain will now pay about £77 per annum instead of £113 10s.

The establishment of a Sectional Committee on Illumination by the British Engineering Standards Association, mentioned in last year's Report, has now been carried out. The British National Committee forms the nucleus of this Committee which also includes twelve representatives of Government Departments, Manufacturers' Associations, and Technical Institutions. Five Sub-Committees dealing respectively with photometers, nomenclature and symbols, illumination glassware, fittings, and street lighting have been set up and have held a number of meetings.

Mr. Walter Waugh, Chigwell Hall, Essex, and of Coronation House, Lloyd's Avenue, E.C., chemical merchant, of Messrs. Blagden, Waugh, & Co., and Messrs. Walter Waugh & Co., left estate of the gross value of £322,010, with net personalty £257,670.

BUXTON CLAY CONVENTION.

Ceramic Society's Meeting.

In connection with the Clay Convention, organized to meet at Buxton, the spring meeting of the Refractory Materials Section of the Ceramic Society was held at the Palace Hotel, on May 19. There was a large attendance, and the proceedings were opened with Mr. J. HOLLAND in the chair.

A recommendation from the Council was adopted, by which North Yorkshire, Durham, and Northumberland were constituted a new district; and three members were elected on the Council to represent the district. It was announced that the autumn meeting would be held at Wembley, as last year. Mr. FRANK WEST, of the Derbyshire Silica Firebrick Company, Ltd., was elected President of the Ceramic Society, and occupied the chair for the remaining portion of the session.

The first item on the lengthy programme of papers was one on "Manufacture of Magnesite," by G. H. REED. In the absence of the author, this was taken as read, and will duly appear with the others in the "Transactions" of the Ceramic Society.

HEAT INSULATION.

Next came a valuable contribution by A. T. GREEN, on "The Heat Insulation of Kilns and other High-Temperature Installations." After a discussion on the losses of heat through kiln walls by conduction, radiation, and convection, the author proceeded to consider the possibilities of avoiding some of this loss by means of insulation—more especially in high-temperature work. The insulating materials available for use in high-temperature work consist mainly of slag wool and diatomaceous earth products. Slag wool has only a very limited application for such work, so that diatomaceous earth products furnish the bulk of high-temperature insulators. Diatomaceous earth, diatomite, kieselguhr, or infusorial earth, as it is variously called, consists essentially of silica; but the natural deposits contain variable proportions of impurities, such as lime, iron oxide, clay, &c., the presence of which is liable seriously to reduce the insulating efficiency of the material in practice.

The essential properties of insulating materials for high-temperature work are low thermal conductivity and high porosity. As a satisfactory guide for successful working, the coefficient of thermal conductivity should range between 0·00025 and 0·00050 at 400° C. The high insulating properties of such materials are in large measure due to the nature and quantity of the pore spaces, the size and disposition of which influence the heat conductivity. It is worthy of note that slag wool with a porosity of 88 p.ct. is not so good an insulator above 450° as diatomaceous earth brick with a porosity of 75 p.ct.; the pores in the latter material being much more minute and disconnected and evenly distributed. Most good insulators have an apparent porosity of between 70 and 80 p.ct.

Pure diatomaceous earth is highly refractory, and retains its porosity at about 1250° C. The presence of lime, iron oxide, clay, &c., in the finely-divided material leads to easy vitrification, with consequent high shrinkage and great decrease in the insulating properties. Slag wool is not reliable for insulating purposes above 700° C. For high working temperatures, a diatomite material containing at least 93 p.ct. of silica and less than 2 p.ct. of lime is necessary.

Insulating methods are extensively used in the iron and steel industry, resulting in fuel economy. In the gas industry the value of insulation is receiving keen appreciation; the results being fuel economy, with increased comfort of the workers in vertical retort plants. The effect of insulation of the tops of the settings by a layer of insulating bricks has resulted in a surprisingly great improvement in working conditions. In some works the fronts of the settings are similarly covered by a layer of insulating bricks. Incidentally, this insulation must give more uniform temperatures round the retorts, as well as some conservation of heat. Many gas engineers are now placing the insulating materials in the walls (instead of on the outer surface), with a view to greater heat conservation and even temperature distribution. In the "GAS JOURNAL" for Nov. 28, 1923, J. S. Thorman, in a paper read to the Southern Association of Gas Engineers and Managers, showed conclusively how insulation makes a waste-heat boiler system very efficient.

In his concluding remarks, the author stated that the selection of insulating material for high-temperature work cannot be based on insulating efficiency alone. It is absolutely essential beforehand to have a complete knowledge of the circumstances of its future use, particularly regarding the face temperature to which it will be subjected. The following data will then serve well in the selection: (*a*) The coefficient of thermal conductivity of temperatures between 300° and 800° C., or the insulating efficiency based on a test simulating industrial conditions; (*b*) percentage porosity, with some description of the nature of the pore-spaces; (*c*) refractoriness (*i.e.*, specification test), with the temperature at which the material disintegrates or otherwise loses its structure; (*d*) crushing strength as an indication of the mechanical strength.

"A Note on the Structure of a Fused Fireclay Crucible," by W. J. REES, B.Sc., F.I.C., was taken as read, and will be published in due course. Mr. REES read a paper by W. HUGILL, B.Met., and himself, on "The Effect of Repeated Burning on the Structure and Properties of Lime-Bonded Silica Bricks." In all, eleven reburnings were made. The results indicate the importance of the "soaking" period of the burn, especially of the first burn. There is very little change in volume after the first burn. Porosity falls steadily down to the seventh burn, with little subsequent change. Crushing strength increases notably to the seventh burn, and after the sixth burn a gradual increase in toughness is very noticeable. Lengthening of the "soaking" period of the burn will decidedly increase the mechanical strength of the bricks.

REFRACTORINESS AND AFTER-CONTRACTION.

Next followed a valuable paper by T. F. E. RHEAD, M.Sc.(Manc.), A.I.C., and R. E. JEFFERSON, M.Sc.(Manc.), A.I.C., of the Birmingham Gas Department, entitled "Notes on: (1) Testing for Refractoriness and After-Contraction; (2) A Few Experiences with Refractories in Vertical Retorts."

In the first part reference is made to difficulties arising in connection with the Institution of Gas Engineers' Specification. The test for refractoriness, first adopted in 1912, and modified in 1922, still leaves the possibility of different results being obtained for the same material, owing to the material being heated (1) to the specified Seger cone or (2) to the actual squatting temperature. A further modification is now proposed as follows: "A definite size of cone ground to the same shape as a Seger cone, with one edge perpendicular to the plane of the base, is heated with the base horizontal to the specified Seger cone, taken from the furnace, and examined with a straight edge, to see whether it shows signs of bending—this bending or matrix running out constituting the definitions of signs of fusion. The rates of heating and oxidizing are as before." It is proposed to call this "The Gas Engineers' Refractoriness Safety Test," to save confusion with the better-known squatting test.

From a routine testing point of view for commercial use, the above safety test offers several advantages: (1) It shows the softening of the material at a somewhat lower temperature than the squatting test. (2) With the squatting test it is very difficult to judge from the appearance in the furnace whether the material is being overheated, and a second test is often necessary. (3) By stopping the heating of the test-piece at the minimum specified zone, the wear and tear on the furnace is minimized. (4) It is much easier to stop a test at a given temperature when using a series of Seger cones than to stop when the test-piece itself shows signs of bending, rounding, or tip touching base. This is because of the additional information given by the behaviour of other Seger cones of the series. (5) The correct rate of heating during the last 100° to 120° C. is a matter of considerable difficulty—especially with a gas-heated furnace. This difficulty is increased the higher the temperature to be attained, owing to the diminishing head of heat between the flame temperature and the test-piece.

The chief signs of fusion which can be detected by the naked eye are: (1) Glazing of surface; (2) bending of test-piece; (3) swelling; (4) loss of angularity of edges; (5) matrix running out; (6) flowing. Many tests by different laboratories seem to show that with fireclay, silicious, and silica refractories a suitably shaped test-piece, heated under specified conditions, begins to bend, or the matrix runs out, either before or as soon as the other signs of fusion appear—with the exception of surface glazing. Mere surface glazing could not be held to represent failure. The amount of bending is the depth of the chord formed by placing a straight edge against the bent edge of the cone.

The refractoriness safety test has two important functions: (1) It determines whether a material has any claim to be classed as a refractory when tested under certain standardized conditions. (2) Being a moderately quick test, it gives the purchaser a fairly reliable check as to the constancy of quality of refractories coming from any particular maker. Too much must not be expected from the test.

The after-contraction test is probably the most important test in the present specification. It throws light on the correctness or otherwise of the heat treatment already given to the refractory by the manufacturer. Unfortunately, the correct interpretation of this test has been shown to be full of pitfalls; the result being affected by furnace design, as well as unequal heating, &c. From results obtained by the authors, it seems questionable whether determining the after-contraction at the one temperature of 1410° C., as per specification, is sufficient with certain refractories—*i.e.*, the composite fireclay-silica brick.

REFRACTORIES IN VERTICAL RETORTS.

Part II. of the paper gives some particulars relating to (1) measurements of the expansion of a vertical setting while being brought into commission; and (2) observations made during the dismantling of a vertical retort setting. The results and observations are discussed in some detail.

A second paper by W. HUGILL and W. J. REES was entitled "The Influence of Iron Oxide and Iron Sulphides on the Rate of Quartz Conversion in Commercial Silica Brick Manufacture." This was taken as read. The results of the investigation showed that the presence of iron oxide or iron sulphide had a favourable effect in increasing the rate of quartz conversion with the same heat treatment, and also in increasing the mechanical strength of the bricks.

Papers by Messrs. L. S. THEOBALD, B.Sc., A.R.C.S., and

A. T. GREEN were also taken as read. They were entitled "Observations on the Elimination of Carbonaceous Matter from Fireclay Bricks" and "An Investigation of the Changes taking place during the Industrial Burning of Fireclay Bricks." They had special reference to bricks made of Stourbridge clay, a Yorkshire fireclay, and a Scottish fireclay, and contained much useful data, &c.

The last paper to be read was by J. & W. B. MITCHELL, entitled "Laboratory Furnace for High Temperatures." This gave an account of a new type of electric furnace in which a metallic resistor is used in the form of a molybdenum wire wound round a small tube; a special contrivance being employed for protecting the metal from the baneful effects of high temperatures. This type of furnace is available for refractory testing, and also for other laboratory purposes, such as metal melting and the standardization of pyrometers at the high-temperature points.

A cinematograph film of the Derbyshire Silica Works was prepared to illustrate the process of the manufacture of carbonizing plants for gas-works.

YORKSHIRE JUNIOR GAS ASSOCIATION.

Visit to the Wakefield Gas-Works.

The Association visited the works of the Wakefield Gas Light Company on Saturday, the 6th inst., with the object of seeing the work of erecting a new bench of horizontal retorts, consisting of six settings of ten retorts arranged in five tiers. The new bench will replace seven settings of eight inclined retorts.

The retort house was built 25 years ago, and contained a bench of inclined retorts consisting of nine settings. Three settings were added in 1908. The horizontal thrust on the discharging side of the inclined settings has distorted the retort house wall; the maximum distortion being 6½ in. As the movement of the wall in the year 1923-4 amounted to 1 in., it was decided where possible to build massive buttresses against the walls. These buttresses are 26 ft. high, 14 ft. at the base, and 23 in. thick, built into the pilasters of the building, which are 20 ft. apart.

It was further decided to remove the inclined retorts, which were worn out, and replace them with horizontals—this work to be done in two stages in separate years, as the Company possess no other carbonizing plant. The horizontal plant is so designed that no thrust from expansion will be carried to the retort house walls; the charging and discharging floors being entirely free from the retort bench.

In order to proceed with the work of demolishing the old settings of inclines, it was necessary to build a new chimney with which to work the remaining five settings, as the flue to the old chimney left the inclined settings at right angles under those to be removed. This chimney was built during last autumn and winter, being completed just in time for its appointed task.

Work was commenced on Feb. 1 by Messrs. Drakes, Ltd., to whom the carbonizing plant and stoking machinery, together with the generating plant, were entrusted. The first section of three settings should be ready for gas making on Sept. 1, and the remaining three settings on Oct. 1. The completed scheme will consist of two benches of six settings of tens. The existing coal plant will be used for a few more years. The coke will be dealt with by a retort-house conveyor to each bench—each feeding to the centre of the house into a yard conveyor arranged at right angles, which will convey the coke either into an existing ferro-concrete hopper or on to the yard as desired. The conveyors are of the "De Brouwer" type, being made by Messrs. W. J. Jenkins & Co., Ltd., of Retford. A 20-KW. generating plant in duplicate is being installed to provide the current for the stoking machinery. The coal conveyors and the coke conveyors will be operated by steam.

The two benches of retorts will have a capacity of 2½ million c.ft. of 500 B.Th.U. gas per day; the output of the superseded plant being barely 2 million c.ft. daily. It may be interesting to mention the fact that the gas sold for the year ended Dec. 31 last showed an increase of 7·37 p.ct. over that sold in the preceding year.

The visitors saw a blue water gas plant under process of reconstruction, and at the same time a duplicate plant in operation. New exhausters made by Messrs. G. Waller & Son, Ltd., and a rotary scrubber by Messrs. W. C. Holmes & Co., Ltd., were also inspected.

Tin Decorating by Gas.—It is stated by the "Intercolonial Gas Journal of Canada" that a large tin decorating works in New York some little while back scrapped an antiquated heating system, and substituted for it modern gas-fired ovens. During the first year this resulted in a fuel saving of $160 a month for four ovens. In addition, two men were shifted to other work, which represented a saving of $55 weekly. At the same time production was increased 17 p.ct. In this way, the new equipment actually paid for itself during the first twelve months of use.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Ventilate the Bath-Room.

SIR,—I have read with interest the paragraph entitled "Ventilate the Bath-Room" in the issue of the "JOURNAL" for May 27 (p. 583).

The suggestions made by your correspondent were, I think you will agree, fully covered in the Report and Specification submitted by the Gas Appliances Specification Sub-Committee to the National Gas Council in May, 1924—see paragraphs 5, 7, and 8 on p. 5 of the Report; also a paragraph on p. 10 of the Specification, headed "Instruction Plate for use with Geysers with Automatic Dual Valves."

INTERESTED.

June 3, 1925.

THE PARAGRAPHS REFERRED TO.

(5) In the opinion of the Sub-Committee the existing type of instruction plate, constructed of a brass plate with stamped lettering, is not sufficiently legible, and it is recommended that an instruction plate (preferably of enamelled iron, with white letters on a salmon-red background) should be affixed to the geyser immediately over the spout, lettered in accordance with the Specification.

(7) *Ventilation.*—It is essential that the room in which the geyser is fitted should be adequately ventilated in such a manner that the ventilation may not be interfered with, but remain permanent. The vent pipe must be rigidly fixed, and not less in diameter than the flue spigot at the top of the geyser, and carried into the nearest chimney flue or through the external wall. In the latter case a suitable terminal or outside wind-guard must also be fixed. When a chimney is not available, or is defective, and the geyser is fixed immediately under a well-ventilated roof space, the flue pipe may be carried through the ceiling and fitted in the manner described in the Book of Instructions for fixing geysers issued by the National Gas Council. No geyser should be fixed without a baffle in the vent pipe, as near to the ceiling as possible.

(8) Two Instruction Cards should be supplied with each geyser—one for the fitter and the other for the user—containing full instructions for the fixing and use of the geyser.

Instruction Plate (for Use with Geysers with Automatic Dual Valves).

This plate to be affixed immediately over the spout and to be enamelled with plain lettering (preferably with white letters on salmon-red background) as follows:

1. WELL VENTILATE THE ROOM.
2. Swing out the burner.
3. Turn on gas tap and light burner jets.
4. Swing in the burner slowly.
5. Turn on water tap slowly.
6. TURN OFF GAS BEFORE ENTERING BATH, and again MAKE SURE that room is WELL VENTILATED.

Heating Bath Water by Electricity.

SIR,—Having received an illuminating publication from you without any cost to myself, I suppose it is only right for me to give you a therm's worth of energy in return. It is rather surprising that some of my recent doings in Leeds should be so extensively known to you, but that my pioneer efforts on your behalf should be unrecognized.

Some ten years ago I had a brain-wave that coal-fired boiler plants at public baths—even granting a thermal efficiency on test of 75 p.ct.—were hopelessly uneconomical and wasteful, by reason of the intermittent character of our business. Owing to the good offices of the Chairman of a Gas Company, I was able to go pretty thoroughly into the matter of water-heating by gas with Mr. F. W. Dye, who was considered to be a most able man, and who had sufficient vision to see that in the heating of water for public baths there was unlimited scope for the gas engineer.

Unfortunately, the particular period was an awkward one for any sort of capital expenditure, and so the germ could not develop. Our idea was a battery of gas boilers sufficient in number for our busy periods, with an arrangement that only one could be utilized for our least busy periods, and that one be thermostatically controlled to give a minimum fuel consumption. Immediately I was able to put the idea into operation, the system was installed. Two very small establishments were dealt with in this way; the amount of water being heated per annum approximating two million gallons. This was only a small beginning; and I would suggest that it did not require a "real live" engineer, but, on the contrary, anyone who was not dead any higher than his boots, to see the wonderful vista of a huge business for the gas people.

Let us see what happened. The Out-Door Manager of the local Gas Company was extremely interested in the experiment, and in working-out fuel costs allowed for the usual trades discount of 35 p.ct. After the plants had been installed, I was surprised to find that the Board of the Company refused to allow me more than the general discount of 2½ p.ct., because public baths were not down on their list of "special trades"; and yet a trouser presser using a single gas-iron came under this special rate. In spite of repeated protests and pleadings, the Company turned a deaf ear.

The "real live" sparks from the wires of Poplar having come into contact with something that was in pretty bad "odour," had to get busy and do what was considered, and by your remarks is still considered, impossible. Poplar, you say, was wrong. The immediate effect was a special reduction of 10 p.ct. in the price of gas. An electric boiler was installed, and then the Gas Company gave way, and allowed the full 35 p.ct. discount. That is the finish of this story, and the "might have beens" have ended.

Regarding my paper, it is not so very surprising to me, after my previous experience, to find that the gas industry is still without "real live" people; for if they had not been "dead from the boots up," they would surely have quoted the free advertisement therein given:

> "When my Committee . . . I installed a series of small gas boilers. The success of this system may be judged by the fact that the cost per bath for gas worked out at 2·23d., at the cost of 3s. 9¾d. per 1000 c.ft., against a coal cost of 5·4d. per bath."

I had not intended to be cynical; but on opening your "JOURNAL," and reading your "Memoranda," I came across the word electricity so often that I wondered if you were out to "boost" your business opponents.

I would just like to say that I am not subsidized by either gas or electricity undertakings, and the personal antipathy of editors towards each other does not interest me at all. I heat about 50 million gallons of water per annum; and the fact remains that the gas people just threw this business away—and who knows how much more?

L. JEFFERSON-HOPE,
Chief Superintendent.

Baths and Wash-Houses Department,
Metropolitan Borough of Poplar,
Roman Road, London, E. 3,
June 2, 1925.

[Reference is made to this subject in the "Electricity Supply Memoranda" to-day.—ED. "G.J."]

REGISTER OF PATENTS.

Apparatus for Lighting Gas.—No. 232,645.

TODMAN, J. C., of Acton, W. 3, and METCALFE, F. E., of Waltham Abbey.

No. 27,600; Aug. 1, 1924.

This invention relates to apparatus for lighting gas by the interposition of a glowing filament in the path of the gas as it emerges from the burner.

The patentees claim: A combined gas and electrical switch for use in gas lighting apparatus comprising the combination with a gas cock of a stationary insulated electrical contact ring and a contact piece moved outwardly into sliding contact with the inner surface of the ring by the initial movement of the parts when the operator exerts a pressure to turn on the gas.

Grids for Purifiers.—No. 232,791.

SPENCER, J. A., of Southall.

No. 12,068; May 16, 1924.

This invention relates to the construction, arrangement, and combination of elements forming grids, for gas purifiers, of the type in which two rows of bars are separated by bearer bars so that the rows break joint; and the object of the invention is an improved construction whereby a series of pockets is formed between the two rows of bars in each grid, which assist in supporting the purifying material in superimposed layers, prevent each layer from unduly settling and varying in density, or the upper layer from falling or settling upon and compressing or increasing the density of the layer below. Only one upper grid is necessary in purifiers 4 ft. deep above the bottom grids, or two upper grids for purifiers 5 ft. or 6 ft. deep.

The grid embodies two rows of bars for supporting the purifying material. The bars are arranged a pre-determined distance apart in each row upon tie rods or cross-pieces of timber which pass through mortised holes therein, and are prevented from shifting their positions by dowel pins or nails. A layer of these support-bars with their cross-pieces is arranged upon each side of bearer bars or distance pieces running at right angles, and the bars in each row are so arranged relatively that they break joint with the bars in the other row.

The design of the grid is fully described and illustrated in the specification.

Purification of Gas.—No. 233,011.

COBB, J. W., and HODSMAN, H. J., both of Leeds.

No. 308; Jan. 4, 1924.

This invention is for an improved process of purifying fuel gases relying upon the use of contact materials, such as iron oxide or iron oxide containing materials, in a heated state for effecting the partial oxidation of hydrogen sulphide by the free oxygen of the gas. According to the claims, the process comprises subjecting the gases to the action of contact materials, such as iron oxide, adapted to secure the partial oxidation of the hydrogen sulphide under conditions of temperature and humidity which will ensure that the free sulphur formed shall be carried forward from the contact bed and that the latter maintains its activity, and utilizing ammonia to enable the removal of sulphur dioxide present after partial oxidation of the hydrogen sulphide to be effected by condensation and washing operations.

The ammonia content of the gas is adjusted to ensure that, under the conditions in which the treatment with hot iron oxide and the further treatment of the gas is carried out, the acidic oxygen containing sulphur compounds may be effectively removed.

After subjecting the gases which have passed through hot iron oxide to condensing and washing processes, they may be passed through a cold oxide purifier to remove any residual hydrogen sulphide.

The patentees give the following example of working. A coal gas prepared for town supply, the composition (by volume) of which when purified would be substantially as follows, was treated:

CO_2	3·0 p.ct.
C_nH_m	2·5 ,,
O_2	1·0 ,,
CO	13·0 ,,
CH_4	24·5 ,,
H_2	37·0 ,,
N_2	19·0 ,,

The gas entering the purification apparatus, in which the iron oxide was maintained at a temperature of 300° C., contained per 100 c.ft. 140 grains of ammonia, 570 grains of H_2S, and 1·9 p.ct. by volume of oxygen. On leaving the apparatus, 50 grains of ammonia, 80 grains of free sulphur as H_2S, and none as sulphur dioxide, and 0·5 p.ct. of oxygen were present in each 100 c.ft. of the gas after washing.

MISCELLANEOUS NEWS.

GAS SUPPLY OF PLYMOUTH.

In Plymouth there are two separate gas undertakings—one at Devonport, the property of the Corporation, and the other at Plymouth, belonging to a Company. Plymouth became possessed of its own gas undertaking when, ten years ago, it spread its tentacles westward and took the naval and dockyard town of Devonport within its grasp. When the Gas Committee presented a favourable report of the undertaking to the Town Council last week, several members urged that its prosperity was an argument in favour of municipalization, and suggested that the acquiring of the Plymouth Gas-Works should be considered.

The Chairman of the Gas Committee (Major J. Clifford Tozer) stated that during the past year the undertaking had made a net profit of £10,524, which would be transferred to the reserve fund. They had had a record output of 792 million c.ft., and had reduced the price of gas by 2d. per 1000 c.ft. His Committee recommended that the salary of the Gas Engineer (Mr. W. P. Tervet) should be increased from £725 to £800 per annum, and thereafter by annual increments of £25 to £850. In arriving at this decision, the Committee had been guided to a large extent by the satisfactory position in which they found the undertaking. The success was in a large measure due to the activities of the Gas Engineer, who had held the position for seventeen years, during which time the output had been trebled.

Mr. E. W. Perry congratulated the Chairman of the Gas Committee on the "magnificent report," and suggested, after such a fine record, they should now acquire the Plymouth Gas-Works, so that the Plymouth ratepayers could join in the pæon of praise. Alderman J. J. H. Moses said things commonly necessary should be commonly owned. Those things essential to the lives of the people should be controlled by the people, and not be in the hands of certain individuals so that they might "squeeze profits." The result of their gas undertaking justified what the Labour Party had been advocating. Mr. G. P. Dymond said the reason why the Devonport undertaking was so prosperous was because it had by its side the evidence of what could be done by private enterprise, so far as the Plymouth Gas Company were concerned. It was not a question of ownership, but efficiency in management. It did not matter whether it was publicly or privately owned.

The minutes were approved.

BURNLEY GAS DEPARTMENT.

In his annual report, Mr. J. H. Clegg, the Gas Engineer to the Burnley Corporation, states that there was a net profit of £38 after payment of capital charges. The price of gas had been 8½d. per therm, and the year's result was far better than was anticipated. The gas sent out showed an increase of 1·85 p.ct., and the gas unaccounted for was 4·52 p.ct. of the make. The sales by prepayment meter were increasing annually, being now 46 p.ct. of the total. After dealing with the slump in residuals, Mr. Clegg states that the department are giving more attention to domestic consumers of coke, and by this hope to lessen the difficulties. If, he says, every gas consumer used a hundredweight of coke per month, there would be no necessity to export a single ton. The production of ammonia was not high enough in his estimation, and he attributed the loss to the inefficiency of the present scrubbing plant, and its small capacity. The sulphate plant was very old, and not now efficient, besides being unable to cope with all the production of ammoniacal liquor last year. A Pelouze and Audouin extractor was now being fixed to improve the results, or, at any rate, to prevent further decline. The average value of the gas supplied was 479 B.Th.U. The waste-heat boiler had relieved the strain on the Lancashire boilers, which had been overworked for some years. By its use, 1600 tons of coke had been saved. The pan ash washer had already recovered 340 tons of coke, and saved £65 in cartage to tip. The full value of these recent installations would not be realized until the coke market was more normal. The new 3 million c.ft. gasholder had been put into use; and when the new governor house was completed this month, gas could be served direct from that station. The whole of the street lamps, with the exception of 28 high and low pressure lamps, had been fitted with controllers, and greater regularity of lighting had been obtained, and a reduction had been made in the number of mantles used. During the past year, sixteen beds in the inclined retort house were reset, and during the present year a further ten settings would be renewed. This would recondition half their plant for a further period of approximately five years. The remaining carbonizing plant and C.W.G. plant was now ready for scrapping, and was very unreliable. These remarks applied also to a portion of the subsidiary plant; and unless the first unit of the new plant at Old Hall was ready for gas-production in the winter of 1926-27, it would be necessary to expend a substantial sum of money on the present works to ensure a proper supply of gas adequate in quantity and quality.

BOLTON CORPORATION GAS ACCOUNTS.

Reporting to the Town Council upon the results for the year ended March 31, the Bolton Gas Committee state that the quantity of gas made was 1,217,213,000 c.ft., compared with 1,178,961,000 c.ft. in the previous year. Mr. Thomas Glaister, Chairman of the Committee, puts on record his appreciation of the support given to him by the Committee, and congratulates the Engineer (Mr. W. J. Smith, B.Sc.) and his staff on their whole-hearted co-operation.

The accounts, prepared by Mr. W. J. Jeffries (the Borough Treasurer) show a gross profit of £66,750. The sum of £14,000 has been placed to the depreciation and renewals fund, the revenue contributions to capital amount to £4008, and a balance of £24,387 remains to be carried forward.

ROCHDALE GAS MANAGER'S RESIGNATION.

Mr. T. Banbury Ball Disagrees with the Policy of the Gas and Electricity Committee.

Reference is made elsewhere in this number of the "JOURNAL" (see p. 719) to the resignation of Mr. T. Banbury Ball, Manager of the Rochdale Corporation Gas-Works, owing to his disagreement with the policy of the Gas and Electricity Committee, who recommended that electricity only should be supplied to 66 Corporation houses to be built. The policy of the Committee—which had been endorsed by the Housing Committee—was debated at a meeting of the Town Council last Thursday.

Alderman BLOMLEY, moving the adoption of the minutes of the Gas and Electricity Committee, said he should feel that he was very remiss in his duty, as Chairman of the Committee, if he did not refer to the resignation of his old friend, Mr. Ball. He would allude to the matter briefly, but none the less sincerely, because during the years he (the speaker) had been a member of the Council he had had the highest regard for Mr. Ball. As a public official, Mr. Ball had rendered exceedingly good service to the ratepayers; and he regretted very much the reason for Mr. Ball's retirement. They knew that the time came for men to retire from public service and from a life of activity, and on behalf of the Committee he could only say they deeply regretted the decision Mr. Ball had come to. ["Hear, hear."]

Alderman WATSON, referring to the Committee's decision to instal electricity only in 66 new Corporation houses, asked whether the Committee had had any communication with the prospective tenants with reference to the matter.

Alderman DIGGLE wished to know whether the decision was come to after hearing both sides.

Alderman DAVIDSON remarked that he supported the question put by Alderman Watson. He would also like to know the circumstances which led to the resignation of Mr. Ball.

Alderman BLOMLEY replied that he was not aware of any request that gas should be supplied to these dwellings. The Committee considered the whole question, and had acted in the usual business fashion. There had been no change of procedure between the Gas-Works Sub-Committee and the Electricity Sub-Committee in dealing with the various questions which had been brought before them. Consultations between heads of the departments had not been held on any previous occasion. Each Manager had brought forward what he thought right and proper for the success of his department. Such communications had been very carefully considered; and the decisions of the Committee and Council had been carried out.

Alderman WATSON was surprised that, in a manufacturing town like Rochdale, the Gas and Electricity Committee should decide against installing gas in 66 Corporation houses. He had raised strong objection at the meeting of the Housing Committee to this decision. Electricity was very useful in a house, but every one could not afford the extra few shillings a week to pay for electric fittings. What would happen, he asked, if, as had occurred, the electric supply failed for some hours—say, when dinner was being cooked? He hoped the Committee would consent to instal gas in these houses.

Councillor R. TURNER said he had hoped the Chairman would have told them something about the experience of other places, which had adopted electricity and no gas in a number of houses.

Alderman WYCHERLEY (the Chairman of the Housing Committee) pointed out that if the electricity supply failed when dinner was being cooked, the tenants would have the coal fireplaces to fall back upon. Looking at the question from the point of view of the Corporation, he understood that in many of the houses there was a very small consumption of gas for cooking purposes. The Housing Committee had ascertained that the following Corporations had installed electricity only (with coal-burning fireplaces) in a number of their houses: Hackney, Woolwich, Newcastle, Glasgow, Marylebone, Norwich, Bolton, Sunderland, Haslingden, and Manchester. A great deal had been said about the cost of installing electricity in these houses. Before deciding the Committee went into the question of cost, and, taking everything into consideration, they were of opinion that the sum was a very modest one, and within the reach of all the people in the town. As compared with gas, electricity was cleaner, healthier, and he believed it was now no more expensive in consumption, than gas. In the case of a particular house among those on the Spotland Estate, in which there was electric lighting and electric power, the cost was: For the September quarter, 15 units for lighting and 219 for power, which cost 1s. 9d. per week; December quarter, 2s. 7d. per week; March quarter, 3s. 7d. per week. He was given to understand, and he could substantiate it from his own personal experience, that it was possible to do the cooking and washing under the modern conditions as to electricity in an ordinary house—ordinary cooking and ordinary washing—for not more than 2d. and 3d. for both on one particular day. He did not think it would be argued that this was beyond the reach of the working man. Surely the Council ought to look forward; and the Committee were of opinion that electricity was a thing of the future, and gas to a large extent a thing of the past.

Alderman DAVIDSON prefaced his remarks with a tribute to Mr. Ball as an old and valued servant with a fine record of service. By his work and his high character, he had gained the respect, the esteem, and the goodwill of everyone with whom he had come in contact. Even the grounds of Mr. Ball's resignation did him credit; for what better proof could be had of a man's keen and conscientious devotion to his department than the action he had taken? He had made a sacrifice, and had shown that he really lived for his department. ["Hear, hear."] It did seem strange that the Council should be asked to go out of their way to say or do anything which would depreciate the gas undertaking in the eyes of customers or ratepayers. In some towns that had been mentioned the gas supply was in the hands of private companies, whereas in most cases the electricity supply was in the hands of the corporation. One could well understand the corporation pushing its own commodity in those circumstances, because in some cases they were out to purchase the gas undertakings, and by reducing their value to get them on the best possible terms. In Rochdale, however, the Corporation owned both these monopolies; and yet they had gone out of their way—by the present policy—to say that gas was played out. At the same time the Gas Committee were proposing to spend £40,000 or £50,000 on their undertaking. In his opinion a very strong case was made out for a separate and independent committee to control the gas-works. He was afraid there might be some difficulty in getting a first-class man to undertake the management of the Gas Department if the Corporation was going to say that they were biased in favour of electricity. Mr. Wycherley had said that the income from gas in respect of the Corporation houses was very small, and that the tenants had really settled the matter themselves. He had heard it stated in the Finance Committee that the gas accounts of these houses were as low as 3d. per house. What were the facts? The capital expenditure on 557 houses for electricity was £5076; for gas £5093. The income from electricity was £141, and from gas £1332, or £2 6s. per house —representing a return of 26 p.c. of the capital outlay. Mr. Wycherley said that there was a small consumption of gas for cooking purposes in these houses; but as a matter of fact there were over 400 gas cookers in use in the 557 houses. No gas was available for lighting because electric fittings had been put in. He hoped the Committee were right in their calculations, and that taking into account the cost of appliances the electricity service would be no dearer than gas. The rents of these houses were high enough; and if on top of the rent the tenants were going to be forced to pay more for electricity than they would have had to pay for gas, it would add very materially to the cost of living. By excluding a gas service from the housing estate the Corporation was virtually proclaiming that gas had been played out, and he was rather disturbed by the proposal.

Alderman CLARK said no one regretted more than the Committee themselves the attitude which had been taken by Mr. Ball. Alderman Blomley and himself had been deputed by the Works Sub-Committee to wait on Mr. Ball and ask him to withdraw the reason given for his resignation. They tried by every possible means to persuade him to do so, because they felt that the service which he had rendered to the Corporation and the town was too good to be spoiled by a reason of this kind. The Committee regretted exceedingly that Mr. Ball should have adopted this as a reason for giving up. The Committee believed that there was a great future for gas as well as for electricity. But on the present occasion the Committee, he believed, were acting in the interest of the Corporation, and the Housing Committee were also of that opinion. They believed that they would be able to save something like £30 or £40 per house by adopting the policy which was recommended. In these circumstances were not the Committee justified in trying an experiment which had already been tried in a number of other towns? One often heard random statements about the cost of electricity, but, as the Council knew, it was a commodity which was coming nearer to the pre-war price than any other commodity he could mention.

Mr. LORD said the Committee were merely desirous of making an experiment. He added that the installation of a dual service of gas and electricity on the Spotland Estate had been criticized by the Ministry of Health, who were of opinion that one service was redundant.

The minutes were passed; Alderman Watson alone opposing them. Similarly, after discussion, the minutes of the Housing Committee were approved—Alderman Watson dissenting.

SAFEGUARDING OF INDUSTRIES ACT.

Gas Mantle Inquiry.

The Committee appointed by the Board of Trade (and presided over by Sir Frederick Mills) to consider the application of the Incandescent Mantle Manufacturers' Association for an import duty on foreign gas mantles resumed their inquiry at the Offices of the Board of Trade, in London, on Thursday, June 4. (The previous proceedings were reported in our issues for May 27, p. 610, and June 3, p. 678).

The whole of the morning session of over three hours was occupied by a long cross-examination of Mr. G. P. H. Soper (for the Mantle Manufacturers' Association) by Mr. Macaskie (who represented the importers opposing the application).

Mr. Macaskie's first questions were put with the object of obtaining an admission from Mr. Soper that the prices of British mantles were fixed by the Association. It was not one of the objects of the Association, said Mr. Soper, to fix prices at which mantles should be sold to wholesalers and retailers. There was an agreement between some of the members of the Association with regard to prices, but the whole of the members of the Mantle Manufacturers' Association were not members of the body who sold at agreed prices. He agreed that a suggestion to the effect that travellers of British manufacturers found no competition from other British manufacturers because prices were fixed between them was substantially correct.

Mr. MACASKIE suggested that, if the British manufacturers had the market to themselves, protected by a very large duty, the price to the consumer would go up very considerably.

Mr. *Soper* felt certain that it would not; the British manufacturers were business men, actuated by ordinary commercial honesty. Even if they were not, however, they had in mind that the duty, if imposed, would be operative only during the pleasure of Parliament, and there might come a time when they would have to ask for it to be renewed.

Asked if he would agree that the German mantle was as good as the British, Mr. Soper said that when he had last compared them his tests had shown that the British mantles were slightly better, but not appreciably better, than the German.

With regard to the importance of the industry from the national point of view, witness said that mantles were used by 8½ million consumers. The number of people who benefited was more than 8½ millions. Another reason why the gas mantle industry was important was that gas at the present time was probably the predominant

source of artificial light in this country. Without the gas mantle, the gas as produced to-day could not be used for lighting.

Mr. MACASKIE pointed out that witness had said that a duty was necessary because the industry in this country was being destroyed by unfair competition, and he asked how it was able to exist before the war, when competition from Germany was keen.

Mr. *Soper* replied that the manufacturers could not carry on their businesses indefinitely in the way they were doing at present. Replying to further questions, Mr. Soper would not agree to the suggestion that the gas mantle industry was a declining one. He admitted that electric light was a serious competitor, but it had not made any material difference, so far as the manufacturers could see, in sales of gas mantles up to the present. If they lost sales in one direction, they picked them up in another; and it was everybody's experience that there was an increased sale of gas burners.

On the question of what was considered to be importation in normal and abnormal quantities, witness said that, having regard to the importance of the industry, he considered that 10 or 15 p.ct. of the total home consumption was a normal amount which might be allowed to come in. The duty should not be of such a heavy nature that it would exclude all foreign mantles, and if only 10 or 15 p.ct were coming in now, he did not think the present application would be made. Asked why he did not suggest that all imports should be stopped, he said he wanted to be fair; British manufacturers did not object to fair competition. He would not agree with Mr. Macaskie that the British mantle industry constituted a trust.

Mr. MACASKIE then put questions with regard to the amount of capital invested in the industry, and ascertained that it was turned over once in 2 or 2½ years at present values. He suggested that that was not a very satisfactory position for an efficiently-conducted industry. The capital invested was about 1½ millions.

Witness pointed out that large extensions of equipment had been made at war-time costs.

The CHAIRMAN said the point was that, if the manufacturers had to carry out extensions again, they would not do it when such high costs were prevailing. He agreed that the Committee had to determine whether the industry was carried on efficiently, but not whether the manufacturers had paid too much for their efficiency.

It was suggested by Mr. Macaskie that there was room for speeding-up production, but witness did not think so. The girls did an honest day's work for their wages, and he had not detected evidence of "going slow" in any factory. Mr. Macaskie suggested that output might be improved by about one-third without much difficulty, but Mr. Soper considered that impossible. Witness did not agree that there were at present too many mantle factories, and that the best two factories could cope with the present home consumption more efficiently and more economically than the existing six factories. In his view, the factories now running could supply the whole of the home demand comfortably, working on full time.

Suggestions were then made by Mr. Macaskie that the German mantles imported into this country were actually offered for sale at 24s. or 25s. per gross, which would compare with the 26s. per gross, the lowest price at which British mantles were offered. Therefore, it was ludicrous to suggest a flat-rate duty of 10s. per gross on German mantles. Mr. Soper did not agree, because the price of 24s. or 25s. represented a profit on re-sale.

Asked by the Chairman why he did not object to Dutch competition, witness said that *bona fide* Dutch competition was very small, and, to be perfectly frank, the manufacturers felt they would have more difficulty in making out a case against Holland than against other countries. As to the possibility of sending British mantles to Germany, he said the import duty into Germany was about 8s. or 8s. 6d. per gross, and nothing but price prevented British manufacturers from selling in Germany. As to the suggestion that the British mantle manufacturers controlled the thorium trade, witness said that one of the mantle manufacturing companies had an interest in thorium, but did not control the price.

In re-examination, witness said that if the demand on the thorium nitrate, ramie yarn, and clay ring factories in England were decreased, they might have to close down, or charge more for their products. He knew of one ramie yarn factory and two or three thorium nitrate factories which had closed down, due to decreased output.

OPPONENTS' EVIDENCE.

Mr. *George C. Sharp* (Agent for the Export Gasglühlicht Gesellschaft, of Berlin) said in evidence that he sold mantles for the German firm to wholesalers and retailers in this country. He handed-in a confidential statement showing the number of mantles which he had sold since 1922, and the prices at which he had sold them. The average import prices of German mantles in 1924 and 1925 which had been given by the applicants, and taken from the Customs returns, he did not regard as representing accurately the prices at which the mantles were sold or offered for sale in this country. They were misleading because they were average prices, and did not state what mantles were referred to. Cheaper mantles than the ordinary standard mantles were imported from Germany; and if they were included in the Customs returns, they would reduce the average prices. Though he had heard statements as to the obliteration of the statement of country of origin on boxes containing foreign mantles, he had not found evidence of this.

MR. TALBOT CROSS-EXAMINED.

Mr. *H. Talbot* (General Manager, Welsbach Light Company, Ltd.) was recalled for cross-examination. At the request of the Committee, he handed in the balance-sheets of the Welsbach Company for the last five years.

The CHAIRMAN, after examining these, said the dividends had been reduced from 15 to 5 p.ct., and a dividend was still being paid on the ordinary shares, chiefly out of reserves.

Witness was cross-examined by Mr. Macaskie as to the information he had given at the previous hearing regarding the wages paid in German factories, and it was suggested that the information was inaccurate. Mr. Talbot said he had every reason to maintain confidence in his figures. He did not wish to disclose publicly the sources of his information, but handed to the Committee a confidential statement of that information, showing the sources from which it was obtained.

With regard to wages paid to girl employees in Germany, Mr. Macaskie said that the amount paid to workers under 19 years of age was 5d. per hour, as against the figure of 2·78d. given by Mr. Talbot, and for those over 19, 5¼d. per hour, as compared with Mr. Talbot's figure of 4¼d.

Questioned as to the prices at which German mantles were sold in this country, Mr. Talbot produced copies of reports from travellers of the Welsbach Company relating to customers who had bought German mantles, and stating the prices at which they were bought. These prices ranged from 18s. to 28s. per gross.

OPPOSITION EVIDENCE RESUMED.

Mr. *Louis Scal* (Director of Messrs. Littleton, Rose, & Co., Ltd., General Traders, of London) gave evidence for the opponents, and said that before the war he was the sole selling agent in this country for the Auerlicht Company, of Austria. The Company did not import at present, because they could not make it pay. He also gave figures as to the prices at which that Company's mantles had been sold here.

The CHAIRMAN remarked that what they had to find out was whether the competition was unfair, and whether the English factories were efficient.

Mr. MACASKIE said he wanted to make it clear that the selling price of German mantles in this country was 24s. or 25s. per gross, as compared with the price of about 21s. which was given by the applicants as the selling price of German mantles.

The CHAIRMAN said the Committee were satisfied with that evidence.

Herr *Heinrich Zeigler* (Managing Director, Deutsche Gasglühlicht Gesellschaft, Berlin), in evidence, said that his Company produced 50 p.ct. of the gas mantles now manufactured in Germany, and before the war they controlled the Welsbach Company. The deposits of monazite sand at Travancore, which it was said were in German hands, had been lost to the Germans. Thorium was sold in Germany at present at 10s. per kilo, and the key industries duty when imported to this country amounted to 33⅓ p.ct. of that; on a gross of mantles it represented about 9d. He agreed that the price of ramie yarn was about the same in Germany as in this country. With regard to wages, he gave details of the increases which had been made since 1923, and said that the hourly rate paid to girls over 19 years of age, including the employers' contribution towards insurance premiums, &c., amounted to the equivalent of 6d. per hour, which compared with 6¾d. per hour paid in this country. As to efficiency in Germany, he said that the quantity of mantles produced in a given time by a given number of workers had increased since 1923. He had not seen the Welsbach and Falk-Stadelmann works at Wandsworth and Earlsfield since before the war; but if they were at present equipped as well as they were before the war, he should say that his own Company's works were as good as those. His works in Germany were equipped with modern installations.

Dealing with the consumption of gas mantles in Germany, he considered that at present it was about half what it was before the war. In reply to Mr. J. Arthur Aiton (a member of the Committee) he said that he had not taken account of Germany's territorial losses, but, even taking these into account, he considered the reduction in the consumption of mantles was about 45 p.ct. His Company's exports to Holland had decreased since the war to a greater extent than the consumption in Germany had decreased.

Replying to questions by the Committee, witness said that labour represented about 30 p.ct. of the cost of production of the mantle. The wholesale price in Germany of similar mantles to those sold here at 24s. 6d. per gross was 21s. 6d. per gross. The carriage, freight, and insurance charges between the German factory and the English port of discharge were about 3s. per gross, so that his Company did not sacrifice anything between the two countries. As to the import duty on mantles imported into Germany, he was indifferent as to whether or not that was taken off. He was giving evidence in the present instance because his Company were responsible for more than 50 p.ct. of the mantles imported into this country.

The CHAIRMAN said he was not in a position to make a bargain, but asked witness whether, if this country and Germany entered into an agreement not to impose an import duty into either country, he would be prepared to beat the Britisher on his own ground.

Witness agreed. As to the number of employees, he said that two years ago, when labour was cheap in Germany, his Company employed from 1000 to 1100 workers; to-day they employed 760, and obtained a greater output.

The CHAIRMAN obtained a promise from the witness to produce at the next sitting of the Committee copies of the recent wages agreements made.

Witness, replying to Sir John Barran (a member of the Committee), said there was nothing in the nature of State control in Germany, and there was no restriction on export. With regard to the consumption of mantles, he said it was the experience throughout the world that less gas burners were used than previously, and that electricity was taking the place of gas for lighting. Great Britain might be an exception.

This concluded Herr Zelgler's public evidence, and he gave information to the Committee privately with regard to costs of production.

In the course of a discussion as to the evidence which will be heard at the next sitting, the Chairman said attention would be directed mainly to wages and costs of production abroad. Further evidence as to the selling prices of foreign mantles in this country, which the opposition have available, was held over for the time being, and will be given if it is considered necessary. Commenting on the question of the alleged deception of British users through the obliteration of the notice of country of origin from the mantle boxes, the Chairman intimated that this fell to the ground as soon as samples of these boxes were examined.

The Committee were of opinion that it was not necessary to hear evidence from Poland, though they did not wish to exclude it.

The Committee adjourned until Tuesday, June 9.

SOUTH SUBURBAN GAS COMPANY'S CO-PARTNERSHIP.

Meeting at the Crystal Palace.

On Saturday last, the co-partners from the various stations of the South Suburban Gas Company met each other and the Directors and officials, at the annual gathering at the Crystal Palace, which is always so much looked forward to by them as an opportunity of showing their faith in co-partnership, as a chance for social intercourse, and as holding out promise of a thoroughly enjoyable afternoon. This year's meeting proved no less enthusiastic, and no less successful in every respect, than its predecessors; but there was one matter on which keen regret was eloquently expressed and even more deeply felt—and that was the absence of Mr. Charles Hunt, who, as the Chairman of the Company, and a thoroughly staunch supporter all along of the enlightened policy which is followed in that undertaking, has endeared himself to all who are in any way connected with it.

Quite early in the afternoon, co-partners, with their wives and children or sweethearts, filled the large theatre in the Palace, and thoroughly enjoyed a concert by the Livesey Hall Silver Star Minstrel Troupe—a large company who proved themselves as expert in their parts as one could possibly wish, under the musical direction of Mr. G. Piper. At the co-partnership meeting which followed, Sir J. FORTESCUE FLANNERY, Bart., presided, and he was supported on the platform by the other Directors, together with the leading officials of the Company and of the co-partnership.

CO-PARTNERSHIP AS A CURE FOR UNEMPLOYMENT.

The CHAIRMAN, on rising, expressed his pleasure at seeing so large an attendance, and his regret—and the regret of all of them—that their dear old friend, Mr. Charles Hunt, was not well enough to be with them. His health had of late not been what they would all have desired. Every one of them would look forward to the possibility of his restored health, and his coming among them once again, with all that geniality and friendliness which had distinguished him for the last quarter of a century in connection with this Company. With each year, as it rolled by, their faith in co-partnership as a system and as a remedy grew and increased. They heard much in the present day about unemployment, and knew that there were something like a million or more of willing workers throughout the country who were without work, however gladly they would take it. It was a serious national misfortune—a problem most difficult to understand and to remedy. Orders were going abroad which a few years ago would have come to this country as a matter of course; and he had often marvelled that the great remedy which they and others in the gas industry had demonstrated by example had not been more generally adopted throughout the manufacturing trades of this great country. It was a remedy by which every worker had a direct interest in the ultimate results of his employment, so that if the whole enterprise was successful he would share in the profits, and feel that every exertion he had made had been a contribution to the common fund from which he is not excluded, as he was by the present system other than co-partnership. By this system of co-partnership, economic production would be increased. The gas industry had led the way, and the South Suburban Gas Company was well in the front rank. It was now nearly thirty years—certainly a quarter of a century—since he first became associated with the late Sir George Livesey in connection with co-partnership. It was just thirty years—from 1894 to 1924—that the record of co-partnership had existed in this Company. The total amount of bonus—quite independent of, and in addition to, the ordinary full standard wage—in these thirty years that has been distributed, not as a gift, but as a matter of contract and right, among the workers of the Company, had been no less than £108,000. This was a very large sum, even over a period of thirty years. To-day the co-partnership system of their Company had 66 pensioners, who held as stockholders £15,000, or an average of over £200 each, in the Company. People might talk about old-age pensions, and about what the State did for them, but where could one find anything equal to this? Here were 66 pensioners—not all of them of the full age, but some in bad health—and the Company did not say to these pensioners: "Have you got other money? Have you anybody else to help you?" Not at all. If they had a claim through age or the state of their health, never mind what they had in the Company, the pensions were awarded according to rule. There were certain very strict rules—and necessary rules, of course—so that justice might be done towards those who continued to work and produce the money that paid the pensions to those who received them. But whenever there was any doubt as to whether a rule applied, the benefit of that doubt was given in favour of the man, and against the Company. Another development to which he ought to call their attention was the reduced number of accidents in the course of the working. This reduction, he believed, might be attributed to several causes. First of all, as they gained experience, they got to know what to avoid so as to secure "Safety First." Secondly, the system of inquisition—of a formal examination—into every accident that took place, be it small or great as regarded injury to the man involved, was thoroughly and carefully carried out. Anybody was heard who could give testimony about the accident, or as to what could be done to prevent a similar happening in the future, and every possible investigation was undertaken. Now they were reaping the reward of this system, because the number of accidents had decreased; and he looked forward to the time when this decrease would be even greater than had been the case up to the present. The workers themselves saw that "Safety First" was a prime consideration—a duty to those who were dependent upon them, a duty to themselves, and a duty to the co-partnership system. A man should run no unnecessary risks. This recognition had been, as he believed, one of the contributing causes to the reduction in accidents—which testified also to the steadiness of the men and their very great care. He never came to a meeting connected with co-partnership without recalling the saying of Sir George Livesey, the father of co-partnership, that the worker was at first a slave, next a wage-earner, and then a co-partner or share in the enterprise. They had reached the third stage; but they had not yet reached the top. There were many good workers who were worthy of co-partnership, but who had not yet been afforded entrance into the nest. But the system was well established; and again he said if any doubt was raised as regarded rules on the question of the admission of any individual to co-partnership, this doubt would be decided in favour of the man, so that, after reasonable trial of his skill and his steadiness, and his worth and deserving to become a co-partner, the co-partnership agreement would be given to him.

CO-PARTNERSHIP FUNDS AND ACCOUNTS.

Mr. JOHN BAKER (Secretary of the Co-Partnership Committee) then submitted the co-partnership account for the year 1924, which showed that the amount of bonus credited to 1407 co-partners was £11,617—being at the rate of 4¾ p.ct. on salaries and wages. The savings exceeded the withdrawals by £1300. A summary of the co-partnership accounts from 1894 to 1924 showed total bonus credited £108,028; and net savings £23,711. With interest, &c., the total sum was £140,903. Of this, £111,754 had been invested in stock, leaving a balance of £29,149. In addition to this balance of £29,149, 1125 co-partners now held £84,988 of ordinary stock of the Company, and 66 pensioners £15,228 of stock. He again pointed out how important it was that all employees possessing over £100 should make a will. The number of accidents which occurred last year was much smaller than in the previous year. The figures were: Last year, 74 accidents, equal to 41 per 1000 men employed, as against 96 (or 60 per 1000) for 1923. This was a reduction of nearly one-third.

THE WORKS COMMITTEE.

Mr. F. CARTER (Secretary of the Works Committee), in presenting the report of the Committee, drew attention to a recent statement of Mr. Baldwin, that an employer who failed to comprehend human nature was not fit to be a leader of men—that the management of the concern was not scientific if it failed to recognize the man in the employ. Mr. Baldwin said that, if they were to make any progress, employers must recognize the necessity for consulting their employees to a far greater extent than they had done in the past; they should offer consultation to the workers on routine, management, and other questions. Again, Mr. Baldwin said there was room for a more intimate relationship in industry than had been experienced in the past. Well, the co-partnership system of this Company was a shining example of all, and more, of the things that Mr. Baldwin thought would stand for progress. They had had for many years that more intimate relationship to which Mr. Baldwin had referred. The Works Committee had always meant far more than mere consultation; they had had powers of a far wider nature than this. They had the power of making representations on behalf of all or any of the workers; they had power to negotiate any matter that came up; and there had been times when the Committee had even had judicial powers. The object and the motive with which the Committee started their work in 1918 were still their object and their motive. He hoped that before very long practically every employee in the Company would have an opportunity of becoming a co-partner.

On the proposition of Mr. T. ANSET, seconded by Mr. F. REED, the report of the Works Committee was adopted.

VIEWS OF DIRECTORS.

Dr. CHARLES CARPENTER remarked that he was very glad to have a chance of again expressing his belief in the principles of co-partnership. He had known Sir Fortescue Flannery for a great many years, and during the whole of that time as an ardent preacher and supporter of co-partnership; and it was a great pleasure to find that his enthusiasm grew greater the longer his association with co-partnership continued. He would also take the opportunity of adding his voice to the regrets which had already been expressed at the absence of Mr. Hunt. Like the Chairman of the present meeting, Mr. Hunt had loyally and consistently, from the very first day of his association with the Company, supported the co-partnership principle; and he thought it would be a kindly act on their part that afternoon to send a message to Mr. Hunt expressing the regret of all the co-partners at his not being present, and assuring him of their continued gratification at his loyal support over so long a period of the co-partnership principle.

Mr. W. G. WALLER seconded the proposal that they should send a letter of sympathy to their beloved Chairman. He also thanked Sir Fortescue Flannery and the other Directors for their very kind invitation to the co-partners that day. There were some present who had come over a hundred miles to attend; and this showed the great interest that was taken in these yearly gatherings. If co-partnership were universally adopted in this country, there would not be over a million of men out of work to-day. They must make of co-partnership a continued success, and then the prosperity of the Company would be assured.

The CHAIRMAN: I shall ask you now to vote upon the motion that a letter of goodwill and encouragement be sent to Mr. Charles Hunt, expressing thanks for his past services to us, and the hope that he will soon be among us again. That is carried unanimously.

Col. J. H. BORASTON also expressed regret at the absence of Mr. Charles Hunt, and his own belief in the principles of co-partnership. He thought these principles were extending gradually throughout the country. In a time of stress in industrial matters such as was now being passed through, men's minds—both employers and employed—were beginning to turn less to their rights and more towards their duties and responsibilities to each other. This, to his mind, was the underlying motive of co-partnership.

Mr. HAROLD GUNDRY remarked that a meeting of this description brought home to one the strength and vitality of co-partnership. As each year came round, he thought they realized more and more the importance of co-partnership to the country. However great an optimist a man might be, he could not think that all was well with industry at the present moment. There was much unemployment. Unfortunately there were dissensions between capital and labour, and foreign countries were quick to notice their chance, and were hurrying to take advantage of the situation and oust this country from the markets of the world. The remedy was co-partnership, which linked

together all parties in true comradeship. One of the most important ingredients of co-partnership was that there should be representation on the Board of Directors, because a man could not feel himself really in partnership if he had not, by himself or his representative, an interest in the management of the undertaking. What their Company had done other companies could do; and he hoped that before long every important undertaking in this country would adopt the great principle of co-partnership.

Mr. JOHN TERRACE (the Chief Engineer) and Mr. WILFRID WASTELL (the Secretary) made some observations particularly affecting the co-partners of the Company, after which a "Safety First" badge and several diplomas were distributed among the drivers of the Company.

Mr. MORRIS INGHAM proposed a hearty vote of thanks to the Directors for their attendance that afternoon. The co-partners, he said, looked forward keenly to these occasions, when they could meet not only their fellow workers, but also the Directors of the Company. [Applause.]

Following Sir Fortescue Flannery's acknowledgment of the vote, the company were entertained at high tea.

NEW GAS-WORKS FOR BURNLEY.

Mr. H. E. Byrne, of the Ministry of Health, conducted a Government inquiry at Burnley last Thursday into the Corporation's application for sanction to borrowing £250,000 for the construction of new gas-works at Old Hall.

The Town Clerk explained that, while the nominal capacity of the existing works was 4½ million c.ft., actually it was not possible to rely upon making more than 3 millions; and as the highest consumption in one day had already reached 3¾ millions, it was clear that the present plant was inadequate to meet the town's present requirements, not to speak of future needs. The total storage capacity was 5½ millions, or 1½ days' supply of gas. The outstanding loans amounted to £117,478. Last year there was a net profit of £28, against £13,827 the year previous. The Gas Engineer said this difference was due to a depression in the industry which had been felt throughout the country; and in consequence the Council had decided to increase the price of gas to cover any possible deficiency. The Inspector drew attention to the fact that the estimated total expenditure was £300,500; and the Town Clerk said that next month the Council intended to apply for aid from the Unemployment Grants Committee. They would then pass a resolution dealing with the difference.

The Inspector said the Council ought to face the facts squarely. The Town Clerk then asked that the application should be regarded as for £300,500.

The gas undertaking, it was stated, had contributed to the relief of rates since 1864 £207,426. The Council had already acquired 23 acres of the land required for the site of the new works. Referring to the old plant at Lanebridge, the Town Clerk said it was very much congested, and had no railway facilities, which meant dependence on canal transport. The Council were of opinion that new works were the most economical proposition, as the old plant, which was installed over thirty years ago, was in an unreliable condition. Maintenance charges consequently were very high, and risk of breakdown considerable; in fact, the Gas Engineer assured him that it would be difficult to meet existing demands if there was a breakdown.

There was no opposition to the application.

GAS EXHIBITION AT NEATH.

A highly successful gas exhibition was held recently by the Neath Corporation Gas Department, at the Gwyn Hall, Neath. The exhibition was opened by the Mayor (Councillor Richard Jenkins), who was supported by members of the Gas Committee, Mr. W. Clark Jackson (Engineer and Manager), and a number of engineers and managers of works in South Wales—including Mr. W. H. Johns (Swansea), Mr. J. H. Canning (Newport), and Mr. J. E. Kenshole (Merthyr Tydfil). The Mayor spoke of the energy and skill put into the gas undertaking by Mr. Jackson; and in the speeches of Mr. Johns, Mr. Canning, and Mr. Kenshole, reference was also made to the excellent work done by Mr. Jackson, both on the works and on the district—it being remarked that Neath ought to be proud of having such an Engineer.

The exhibition consisted of four demonstration rooms, set-out as dining room, drawing room, kitchen, and bathroom. They were furnished in a tasteful manner by the South Wales Furnishers, and fitted with the latest designs of gasfittings, gas fires, hot water equipment, &c. There were also a number of tableaux displayed around the hall representing the usefulness of gas, and two large stalls—one showing heating and cooking apparatus, and the other gasfittings. The cooker stall was arranged by Radiation Ltd., and the gasfittings by Messrs. Falk, Stadelmann, & Co., Ltd. Cookery lectures and demonstrations were given twice daily by Mrs. Dora Rea.

During the week it remained open the exhibition was attended by approximately 6000 people, and the turnover of business in sales amounted to about £1200.

A children's essay competition was also organized; 24 selected scholars (12 boys and 12 girls) from each of the schools in the district taking part in this. The essays were of a high standard, and caused great interest, as was shown by the large attendance of parents and scholars at the final lecture, at the conclusion of which the prize-giving took place—the prizes being presented by Mrs. Jackson, the wife of the Gas Engineer.

Excellent results have accrued from a series of lectures and demonstrations on the use of gas in cookery at the showrooms of the Alliance and Dublin Consumers' Gas Company. Miss Bonham Carter was the lecturer and demonstrator, and she had large and interested audiences.

WHESSOE FOUNDRY AND ENGINEERING COMPANY.

Satisfactory Results in Difficult Year.

The Fifth Annual General Meeting of the Whessoe Foundry and Engineering Company, Ltd., was held last Friday at 8, Frederick's Place, Old Jewry, E.C., Mr. H. S. SMITH-REWSE presiding.

Mr. S. LANGFORD (Joint Secretary) having read the notice convening the meeting and the report of the Auditors,

The CHAIRMAN said: Gentlemen,—I regret that our Chairman is absent to-day, owing to the illness of his wife abroad, and your Directors have asked me to take the chair in his absence. I presume that, as usual, I may take the Directors' report and accounts as read. [Agreed.]

The results of the past year are, I think, on the whole, satisfactory. At our last meeting we expressed the hope that the trade depression was showing signs of improvement; but, unfortunately, the outlook at present still seems far from clear. Prices are still very keenly cut; and it is only by the closest attention to efficiency and economy in manufacture that we have been able to maintain our profits on such a comparatively satisfactory level through a difficult period.

There are no alterations in our balance-sheet from last year to which I should draw your attention, except that our work in progress has fallen; but I am glad to tell you that since the date of this balance-sheet we have received our fair share of orders, which should keep the works employed.

NEW MANAGING DIRECTOR.

During the year we suffered a very great loss by the death of our Managing Director, Mr. Alfred Coates, who had been connected with the works practically since boyhood, and to whose energy and ability the success of the Company must in large measure be attributed. This loss at such a time of depression in trade was bound to increase our difficulties; and I think we should congratulate our management and staff on the manner in which, in spite of this sad event, they have succeeded in carrying on the work.

I am glad to say that we have been very fortunate in securing the services of Mr. R. B. Hodgson (who to-day is Director and General Manager of Messrs. Ashmore, Benson, Pease, & Co., Ltd.). He will join the Company as Managing Director on the 1st of July, when the Directors propose to elect him to a seat on the Board. Mr. Hodgson has had great experience of the trade in which this Company are engaged, and I am glad he is able to be present with us to-day.

I now beg formally to propose the adoption of the report and accounts. I will ask Mr. Cripps to second the motion; but before putting it to the meeting, I shall be glad to answer any questions.

The Hon. A. H. SEDDON CRIPPS seconded the resolution, which, in the absence of questions, was carried unanimously.

The CHAIRMAN: I now have pleasure in moving: "That a dividend of 10 p.ct., free of tax, as recommended by the Directors, be paid for the year ended March 31, 1925;" and if you approve of this, the dividend warrants will be posted to-morrow.

Mr. CLAUDE M. SPIELMAN seconded the motion, which was unanimously approved.

Mr. HARRY CLAYTON proposed the re-election of Mr. H. S. Smith-Rewse as a Director, which was seconded by the Hon. A. H. SEDDON CRIPPS, and passed unanimously.

The Auditors (Messrs. Peat, Marwick, Mitchell, & Co.) having been re-appointed, the proceedings terminated.

Flats Specially Built for Gas Fires.

A new departure in flat construction which, owing to its great saving in costs, is likely to be widely adopted, is to be introduced in a block of labour-saving flats at Knightsbridge Court, Knightsbridge. The foundation is being laid in this thoroughfare of a ten-storey building, which will embrace sixty labour-saving flats of varying dimensions, each specially constructed for the use of gas fires. The chief novelty from an architectural point of view is the abolition of the chimney. In place of wide brick chimneys, narrow flues constructed with "Nautilus" cast-concrete gas flue-blocks will be installed. These blocks have been approved by the Ministry of Health and the London County Council. By dispensing with the ordinary chimney, structural economies will be effected. In doing away with foundation concrete, brick footings, projecting chimney-breasts, trimmers, skewbacks, arches, concrete hearths, and large brick chimney-stacks, it is estimated that about 500,000 bricks will be saved. On each stack the economy will be as much as £100.

Omagh Gas Undertaking.—The past year's working of the Omagh (Co. Tyrone) Gas-Works shows a profit of £1479, as compared with £1679 in the previous year, the decrease being attributed to a reduction in price of gas from 6s. 8d. to 5s. 10d., which came into operation in the March quarter, and the increased expenditure on gas cookers and retorts.

Nelson Gas Department.—In his report for the year ended March 31, Mr. James Mitchell, Engineer and Manager of the Borough of Nelson Gas Department, says that the net profit was £7277. The total quantity of gas made was 531 million c.ft., all of which was coal gas. The net income from residuals amounted to £20,715, compared with £25,078 last year, which gives a return of 15s. 4d. per ton of coal carbonized, as against 17s. 11d. last year. As compared with the previous year, ordinary meters show an increase in consumption of 1·77 p.ct., and prepayment meters 6·69 p.ct., making a total increase of 4·31 p.ct. The unaccounted-for gas stands at 4·1 p.ct. During the year 354 gas cookers, boilers, fires, &c., were sold outright, and 624 appliances on the hire-purchase system. The Brierfield installation of vertical retorts has been reconstructed, and the expenditure has been fully compensated by an increased production of gas and residuals per ton of coal carbonized.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

Business has entirely failed to benefit from the Whitsuntide holiday, and many collieries extended the break beyond the Monday. Idle time has been more than ever rife, and notices are still being given almost daily. Prices have been lower than ever, and buyers who have orders to place for prompt shipment can more or less make their own terms.

It is becoming more and more obvious that the collieries will just have to carry on as best they can, and cut losses as far as possible, until the crisis which is bound to come at the end of the present agreement.

Gas coals, like all others, are in very meagre demand. Wear Specials quote 18s. 9d., and best qualities 18s. 3d. to 18s. 6d. f.o.b. These prices are purely nominal, and prompt sales are subject to negotiation. Seconds, likewise nominally, are 16s. 3d. to 16s. 6d. Unscreened coking is 15s. 9d. to 16s. 3d., and a very limited market; supplies of all qualities being freely offered. Best Durham bunkers are weaker, and obtainable at 16s. 6d. to 16s. 9d.

The loss to collieries at these f.o.b. prices amounts in most cases to shillings a ton, and still they are too high to compete successfully for such limited business as is offering in the Continental markets.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

There is no material alteration in the Yorkshire and Lancashire coal trade this week.

Gas coals continue to be placed on the contracts over twelve months, and evidently there is a feeling that the next four weeks or so is the time to purchase owing to the general uncertainty likely to prevail throughout the trade during the next few months. Prices continue to vary, and there does not seem to be a generally stabilized price list, such as existed in more normal times.

House coal is naturally in small request, while there does not appear to be any improvement among the larger coal-consuming industries. The iron and steel trades may have a chance of recovering to some extent, seeing that furnace coke is now being put on the market at much reduced figures. This will enable British competitors to be more successful in the near future. Low prices continue to rule for the commoner grade fuels, and it remains to be seen what effect this will have after the holidays.

The shipping outlook continues abnormal. Although low figures are quoted for the various qualities, exporters report that there is no chance of an improvement for some time. With the possibility of increased working hours and the consequent reduction in the cost of production, it may be, however, that towards the latter part of the summer there will be an improvement.

The Humber bunker and export prices (f.o.b. usual shipping ports) are: South Yorkshire.—Hards, Association, 19s. 6d.; screened gas coal, 17s. 6d. to 18s.; washed trebles, 18s. to 19s.; washed doubles, 16s. 3d. to 16s. 9d.; washed singles, 15s. to 15s. 6d.; washed smalls, 10s. 9d. to 11s. 6d.; unwashed doubles, 15s. 6d.; rough slack, 10s.; smithy peas, 18s. to 19s. 6d. West Yorkshire.—Hartleys, 16s. 6d. to 18s.; screened gas coal, 16s. 6d. to 18s.; washed trebles, 17s.; washed doubles, 14s. to 15s.; washed singles, 13s. 6d. to 14s. 6d.; washed smalls, 10s. 6d. to 12s.; unwashed trebles, 16s.; unwashed doubles, 12s. to 13s.; rough slack, 9s. 6d. to 10s.; coking smalls, 9s. to 10s. Derbyshire and Notts.—Top hards, 19s. to 19s. 6d.; washed trebles, 17s. to 17s. 6d.; washed doubles, 16s.; washed singles, 14s. 6d. to 15s.; washed smalls, 10s.; unwashed doubles, 14s. to 14s. 6d.; rough slack, 9s. 6d. to 10s. Yorks, Derbys, and Notts.—Screened steam coal, 15s. to 17s.; gas coke, 19s. to 20s.; furnace coke, 15s. 9d. to 16s. 6d. per ton.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Many gas undertakings are anything but eager to complete contracts for the new term. The course of the market gives some encouragement to the belief that by delaying they risk nothing and may enforce better conditions. Colliery managements that take the market position as standardizing prices of gas coal at from 2s. to 3s. below those which ruled a year ago are being told that supplies can be arranged with some of their competitors at a reduction of 5s. This is considered an exaggeration of the slump.

It is evident that some collieries are prepared to shade late prices rather than lose contracts. Stabilized prices are not to be expected in prevailing conditions. But a drop of 5s. is considerably more than collieries generally are prepared to entertain. It is suggested that the price agreed last year for high-grade coal is being compared with the price now quoted for low-grade coal to arrive at the difference of 5s. Notwithstanding the suspension of output during the Whitsun holiday, supplies of all descriptions of fuel continue greatly in excess of demand. Values have, therefore, further depreciated.

Iron and steel producers have not sufficient orders to warrant more than a partial re-starting even of the plants that were in operation down to the eve of the holidays. Further closing down of pits appears to be inevitable, and at many of these where coal getting has been resumed working hours are being further curtailed.

The half-yearly meeting of the Lampeter Gas Company was held last week—Major Harford presiding. The Directors submitted their report and balance-sheet for 1924, which showed a profit of £291. It was decided to apply this towards the reduction of the accumulated debt of previous years; the Directors being unable to pay a dividend.

TRADE NOTES.

New Holder at Clevedon.

Messrs. Thos. Piggott & Co., Ltd., of Birmingham, have secured the contract for a three-lift gasholder and framing, to replace one of the existing holders at the Clevedon Gas-Works, Somerset. The work is to be carried out under the direction of the Engineer, Mr. J. Harger Pye.

Cambridge Instrument Company, Ltd.

This firm have published a new list describing "Cambridge" automatic temperature regulators. Readers of the "JOURNAL" will be interested in the apparatus described, which has important applications in practically every branch of industry. Though the catalogue deals almost exclusively with the regulation of temperature, the regulators described can be applied with equal efficiency to the automatic control of humidity, pressure, and other physical conditions.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *June* 8.

There is no change to report in the position of pitch, the price of which remains unaltered.

Creosote also is unchanged at about 7d. to 7½d. per gallon.

Solvent naphtha, 95/160, is 1s. 9d. per gallon.

Pure benzole and pure toluole is 1s. 11d. to 2s. per gallon.

Tar Products in the Provinces.

June 8.

Markets for tar products generally are still very dull. There is practically no business doing for prompt delivery, while prices ruling are generally so low that there is no inducement to manufacturers to contract for forward.

Pitch is still very quiet indeed. Sales are reported on the Continent on the basis of 39s. to 40s. per ton f.o.b. England.

Creosote is steady. There is not a very large demand for home consumption, while as regards export buyers appear to have covered their immediate requirements, and apparently prefer to wait before booking for the latter part of the year.

Benzole is in good request at full prices.

Solvent naphtha is in good demand, and contracts are reported to the end of the year at fair figures.

Carbolic acid crystals are still neglected, and crude carbolic acid is very dull and difficult to sell.

Naphthalene continues depressed by the prices quoted by Continental manufacturers.

The average values for gas-works products during last week were: Gas-works coal-tar, 26s. to 31s. Pitch, East Coast, 39s. to 40s. f.o.b. West Coast—Manchester, 34s. to 35s.; Liverpool, 35s. to 36s.; Clyde, 38s. to 39s.; Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8½d.; crude, 65 p.ct. at 110° C., 1s. to 1s. 1d. naked at makers' works; 50-90 p.ct., naked, North, 1s. 7¼d. to 1s. 8¼d. Toluole, naked, North, 1s. 6½d. to 1s. 7½d., nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 5¾d. to 6d.; salty, 5½d. to 5¾d.; Scotland, 5¼d. to 5½d. Heavy oils, in bulk, North, 6½d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality, 2½d. per minimum 40 p.ct., purely nominal; "B" quality unsaleable.

CONTRACTS OPEN.

Coal.

The Tipton Urban District Council are inviting tenders for the supply of 12,000 tons of gas coal. [See advert. on p. 757.]

The Denbigh Gas and Coke Company are inviting tenders for about 1900 tons of best screened gas coal. [See advert. on p. 756.]

The Teignmouth Urban District Council Gas Department are inviting tenders for the supply of 2500 tons of coal. [See advert. on p. 756.]

Tenders are invited by the Evesham Corporation for the supply of from 500 to 8000 tons of best screened gas coal. [See advert. on p. 756.]

Tenders are invited by the Keighley Corporation for the supply of about 35,000 tons of best screened gas coal, nuts, and slacks. [See advert. on p. 756.]

The Gas and Water Undertaking Committees of the Borough of Saffron Walden are inviting tenders for the supply of gas and steam coal. [See advert. on p. 756.]

Tar and Ammoniacal Liquor.

Tenders are invited by the Gas Committee of the Loughborough Corporation for the purchase of their surplus tar and ammoniacal liquor. [See advert. on p. 756.]

EXTENSIONS.

New Purifiers for Blackpool.

It is proposed to put down two new purifiers at the Blackpool Gas-Works, subject to the Unemployment Grants Committee authorizing a grant. This will entail application to the Ministry of Health for sanction to borrow £5500.

Questions Investors Should Ask.

One of the largest gas companies on the Pacific Coast recently issued a leaflet urging the advisability of prospective investors securing answers to the following twelve questions before placing their money in any enterprise of which they possess no personal knowledge: (1) Is the industry well established—that is, safely past the experimental stage—and showing a healthy growth? (2) Is the investment backed by actual physical property sufficient to justify the company's capitalization? (3) Has the security paid interest or dividends consistently over a period of years, and is it now yielding a satisfactory return, rather than carrying an indefinite promise of dividends at some time in the future? (4) Is the business stable in character, dealing in commodities for which there is at all times a ready market? (5) Is the territory in which the company operates progressive, presenting favourable opportunities for future development? (6) Does there exist an active market for the security, so that stockholders may sell their holdings at any time if occasion requires? (7) Has the business a sufficient working capital to meet any contingencies which may arise, even in those periods of industrial depression which inevitably occur from time to time? (8) Is the security of such character that your bank will accept it as collateral for loans? (9) What is the character of the company's management and personnel? (10) Is the enterprise of sufficient size to withstand the stress of active competition from other companies engaged in similar business? (11) Is there any assurance that the money paid for purchase of stock actually will be invested in the business, instead of going into the pockets of promoters? (12) Is complete information regarding the company's progress and operations available to stockholders?

Irish Gas Price Reductions.—The Newry Urban Council have reduced the price of gas by 5d., to 5s. 5d. per 1000 c.ft. Gas for heating and cooking purposes has been reduced in price by the Coleraine Urban Council by 5d., to 4s. 2d. per 1000 c.ft. In Strabane the price of gas has been reduced by 9d., to 6s. per 1000 c.ft.

Newbury Gas Department.—Owing to a reduction in the price of gas, the surplus on net revenue account for the past financial year of the Newbury Corporation Gas Department amounts to £281, as compared with £2452 for the previous year. The Auditor states that the cost of production and distribution compare favourably, and carbonization results show a substantial improvement. The percentage of unaccounted-for gas has been substantially reduced.

Malta and Mediterranean Gas Company, Ltd.—The audited accounts for the year ended March 31, which will be presented at the meeting next Tuesday, show that, after appropriating the sum of £4000 to reserve, the amount standing to credit of profit and loss account is £13,704. The Directors propose the payment of the dividends on the first and second preference capital, and a dividend of 3¾ p.ct. (free of income-tax) on the ordinary capital—making, with the interim dividend, 6 p.ct. for the year.

Leek Gas Undertaking.—At a recent meeting of the Leek Urban Council, the report of the Gas Engineer (Mr. R. H. Ginman) for the year ended March 31 was considered and approved. It was recommended that the price of gas to ordinary consumers in Leek be reduced to 3s. 6d. per 1000 c.ft., less a discount of 6d. per 1000 c.ft. for prompt payment, and that the price to ordinary consumers at Rudyard be reduced to 4s. 6d., with the same discount. It was also recommended that the discount allowed to prepayment consumers in Leek be advanced from 5d. to 8d. per 1000 c.ft., and to prepayment consumers in Rudyard from 4d. to 7d. per 1000 c.ft. The net results of the year's working showed a loss of £1900.

Lytham St. Annes Gas Department.—The accounts of Lytham St. Annes Gas Department show a loss of £1381 on the year. The revenue was £57,284, and of this £57,879 came from the sale of gas, £14,221 from residual products, and £3594 from services, fittings, &c. Gas sales show a decrease of £2000, and those of residual products £500. The total expenditure was £46,846, compared with £57,168 last year, while the costs of manufacture were reduced to £32,863, from £34,263. Distribution expenses fell from £13,638 to £7341. This year the gross profits were £10,438, against £4598 last year; but sinking fund and interest charges were £11,819, compared with £7567. The net loss last year was £2950.

Progress at Workington.—Alderman F. Hall (the Chairman of the Workington Corporation Gas Committee), submitting the annual report of his Department to the Town Council, congratulated Mr. Hedley Hoy (the Engineer and Manager) on the results attained. He said the progress made was of such a character as could not have been possible unless the coal had been wisely selected, the carbonizing plant up to "concert pitch," and the management and employees keen and reliable. The make of gas had been nearly 183 million c.ft., or 7½ millions more than in the preceding year; the make per ton of coal having been 20,396 c.ft., or 479 c.ft. more. The gas sold per ton was 19,058 c.ft., or 82·1 therms. The vertical retort installation has worked satisfactorily during the year.

Price of Gas at Hereford.—At the last meeting of the Hereford Town Council, the Gas Committee reported that, "in consequence of the serious slump in the value of residuals, amounting in the financial year just ended to £1067, and of the estimated further fall in value of £2400 during the current year, the Committee were compelled to recommend the Council to increase the price of gas, as from June 24, 1925, from 4s. 3d. to 4s. 9d. per 1000 c.ft., less the usual discount of 3d. per 1000 c.ft. for prompt payment. A corresponding increase was recommended to consumers on the prepayment system viz., by reducing the discount from 1s. to 6d. per 1000 c.ft." Mr. Oatfield, who moved the adoption of the report, in the absence of the Chairman (Alderman C. Witts), mentioned that, whereas the income from residuals per 1000 c.ft. of gas was 11d. in 1904, and 2s in 1921, it was only 8d. last year. During the past two years, the Committee had endeavoured to give the citizens cheap gas, which had resulted in serious losses; and now they thought it fair to ask consumers to pay a reasonable price. The report was carried.

STOCK MARKET REPORT.

THE weakness of gilt-edged stocks was the feature of the week on the Stock Exchange, for which various reasons have been assigned. The failure of the recent new issues and the possibility of a new conversion scheme being attempted are the principal of these reasons; but the fact remains that there have been many large sellers, and the absence of compensating buyers has resulted in a general depreciation all round. The outlook is not improved by the knowledge that other important loans will appear on the market at an early date. There is a silver lining to every cloud, and there were a number of purchases by trustees of stocks that are rarely available.

There is nothing of note to report in the other principal markets. Foreign Government and Foreign and Home Rails were all quiet. Industrials were colourless except the popular issues. Tobaccos, Real and Artificial Silks all improved. Courtaulds rose above the £5 mark. Imperial Tobacco, Dunlops, and Allied Newspapers all showed increases on the week. Electric issues have obtained a good deal of advertisement of late by reason of the various grandiose schemes that are being promulgated. The dividends have been gradually improving, but consideration should be given to the heavy capital expenditure that is being incurred.

Transactions in the Gas Market were less than usual, and the changes in the quotations were unimportant. The Imperial Continental ordinary is gradually losing the inflated value that arose out of the special distribution. The present average price—14½—on an estimated permanent return of 10 p.ct. would yield 6·66 p.ct.

An issue is announced of £8000 6½ p.ct. Irredeemable Preference Stock at a minimum of par by the Wells Gas Light Company.

The following transactions were recorded during the week:

On Tuesday, Alliance and Dublin 63, Commercial 3 p.ct. debenture 57½, Continental Union 34, European 6⅞, 7, Gas Light and Coke 83⅜, 83⅜, 84⅛, 4 p.ct. preference 79, 79½, Hastings and St. Leonards 3½ p.ct. 75⅝, Imperial Continental 148, 150, 151, 153 *ex* div., Montevideo 68, Primitiva 9s. 10½d., 10s., South Suburban 5 p.ct. 95, Tottenham "B" 95.

On Wednesday, Gas Light and Coke 83½, 83⅜, 84, 84⅛, 84⅜, 4 p.ct. preference 79½, Imperial Continental 147, 147½, 149 *ex* div., Montevideo 67, 68, 68½, Primitiva 10s. 1¼d., South Metropolitan 93⅜, 94¼, Tottenham "B" 95, 5½ p.ct. preference 104¼, 104½, Wandsworth 130, "B" 110, Epsom stock 112. Supplementary prices, Colonial Gas Association 7 p.ct. preference 18s. 6d., Gravesend and Milton 65.

On Thursday, Alliance and Dublin 65, Bombay 97s. 6d., British 111, Gas Light and Coke 83⅜, 83⅜, 84, 84¼, 3½ p.ct. maximum 62⅜, 4 p.ct. preference 79, Imperial Continental 147½, 148, 148½, 148⅜, 149 *ex* div., Montevideo 68½, 68¾, Primitiva 9s. 9d., 9s. 10½d., 10s. 3d., South Metropolitan 93⅜, 93⅜, 94, 94¼, 6⅜ p.ct. debenture 103½, Wandsworth "A" 130, "B" 110, 5 p.ct. Epsom stock 112.

On Friday, Bournemouth 6 p.ct. preference 11⅛, 11⅜, Brentford "A" 96⅞, Brighton and Hove original 167, Continental Union 33⅛, European 6⅞, Gas Light and Coke 83¼, 83⅜, 83⅜, 84, 3½ p.ct. maximum 62½, Imperial Continental 149 *ex* div., Primitiva 9s. 9d., 10s., South Metropolitan 93⅜, 6½ p.ct. debenture 103⅞, South Suburban 5 p.ct. 96, Southampton 5 p.ct. 80½, 80⅜. Supplementary prices, British, Norwich 3½ p.ct. mortgage debentures 62, 62½, Reading 5 p.ct. 82, 82½, Redhill "B" 82, 82½, Southgate and District 5 p.ct. debenture 98⅛, 98½.

Money was perhaps easier in Lombard Street. Old day-to-day loans were renewed at 3⅜ p.ct. and declined later to 3½ p.ct. The Treasury Bills average rate rose again from the previous week's rate of £4 6s. 4·48d. to £4 7s. 6·62d. p.ct.

The continued weakness of the franc dominated the Foreign Exchange Market. With both Paris and New York selling, the value fell to 103.05 on Saturday, finishing about a franc less. Belgian francs suffered in consequence, and closed at 104.10. Italian lire were 122½ to the £. Sterling on New York was very steady. Business was done at 4.86⅛, but closed at 4.86.

Silver was affected by Chinese sales, and the price for cash fell to 31⅜d. per oz. Gold remained unchanged at 84s. 11½d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3½ p.ct. at notice.

EDITORIAL NOTES.

The Institution Meeting.

As we glance over the doings of last week, at the annual meeting of the Institution and in conjunction with it, it must first be said that it was a brilliant success. Such a success is not due to a single feature, but to many—ranging from presidential energy and admirable direction, numerical representation, sustained interest through the quality and current appropriateness of the topics before the members, to the attendant attractions, and the contribution of exquisite weather. Those who were participants found all these traits; and the mainspring throughout was the President (Mr. J. Ferguson Bell, M.Inst.C.E.), whose zeal in seeking to maintain the best traditions of his office and his loyalty to the interests of the industry so attracted the attentions of Old Sol that his enthusiasm was almost unbounded. Everybody concerned in the meeting is grateful to the President and his great luminous ally. It was a happy and profitable week, with no blank spaces in it. It brought home to us the great expanse of the interests of the industry, of the universality of its work, and of how through efficient organization we are causing other people to become more and more interested in our affairs. This last-mentioned aspect shows a trend in the right direction; and every means and opportunity should be taken to cultivate it. The industry has been all too content to live and to serve and have no associates beyond its own boundaries. This is a mistake; the present proves it with influences at work in high places which are not to the advantage of the industry. But the mending or changing of this deficiency is now in process of development; and our claims and far-reaching importance in the system of affairs and service are becoming better known. There is much to be done and to be maintained in this direction. Fortunately the industry is in the guiding hands of those who fully realize this, and are working to make new friendships where they are wanted—not for the purpose of gaining any undue consideration, but to ensure that knowledge of us is what it should be. At the meeting last week, there were men from the political world. On one occasion the President and Council of the Institution had the pleasure of entertaining one of His Majesty's Ministers (the President of the Board of Trade), and an ex-Minister and leader in the Labour Party (the Right Hon. J. H. Thomas), while at another stage in the proceedings the Right Hon. Sir Alfred Mond, Bart., addressed the members. This is as things should be. We want, too, to encourage inter-relationships abroad. We have both technical and commercial interests to serve; and a better knowledge of us by our friends and by us of our friends and of each other's work and advances will be mutually helpful. On this occasion members of the profession from the Continent and from far overseas came to, and took part in, the meeting. The President of the Société Technique du Gaz, through M. Baril, contributed an item of large interest on the subject of tankless gasholders, which, with the discussion, has assisted considerably in clearing away or thinning down doubts regarding these structures.

In the succeeding article, comment is made upon the Presidential Address, and preceding the General Report there is a review of the entire proceedings. There are certain of the reports and papers upon which comment may be deferred. The members were gratified with the excellent report made by the Education Scheme Committee, which was presented by Mr. F. W. Goodenough. For such an innovation as this scheme, it shows excellent progress, considering these are early days in its career. It is making history, because what is being done is going to be of untold advantage to the industry in equipping it with men specially trained for its service and responsibilities. Good work has been done for a number of years by the Gas Investigation Committee, through the researches carried out under the direction and supervision of Prof. Cobb at the Leeds University; but the past year has been largely occupied in preliminary work on the Corbet-Woodall memorial experimental plant, which we confidently predict is going to be invaluable in increasing the scope of research. The Gas Investigation Committee would, Mr. Thomas Glover says, be pleased to receive for consideration suggestions as to work which should be taken in hand. One is a thorough research into coke production. We can think of no line of investigation which would be at the present time of greater service to the industry; and the sooner it is taken in hand the better. From the references to coke in one of the reports, we think that Prof. Cobb and his staff have this in mind. There is much need for precise information as to the physical qualities of coke which, without sacrificing our high temperatures in carbonization, will give good ignition and combustible virtues to the product. Having obtained this information, the industry requires to know the blends of coal and other conditions which will best yield such coke. There is also the questions of mixing a proportion of coke with coal charges, and the definite ascertaining of the effect this would have upon the transmission of heat through a charge, upon the throughput and productivity per retort, and upon the ability to use lower temperatures with advantage to the life of the refractory materials of which retorts and settings are composed. There is a connection here between the hoped-for investigation at Leeds and the Joint Refractories Research Committee's work. As Sir Arthur Duckham said, if we can get a carbonizing plant to have a longer life, the costs of carbonizing will be reduced considerably; and this will materially affect the net cost of gas. The Wrought-Iron Tubing Committee, under the chairmanship of Mr. Albert Stokes, have quickly got well into their work; and it is easy to predict a valuable result in the shape of a specification and test. The engineering and other papers—to which reference will be made as opportunity permits—by Sir Dugald Clerk, Prof. C. V. Boys, Mr. W. M. Carr, and Mr. George Evetts were in several respects of first-class importance.

Hearty congratulations and good wishes are offered to the new President (Mr. C. F. Botley, of Hastings), and to Mr. John Wilkinson and Mr. H. D. Madden upon their advancement along the road to the Chair of the Institution. The great enjoyment which the President and Mrs. Bell gave the members on Tuesday night will long be remembered. The intellectual treats provided for the members by the Gas Light and Coke Company, the South Metropolitan Gas Company, and the National Physical Laboratory were highly appreciated. And as to the excursion on Friday, it was the happiness of the Chairman (Mr.

W. Woolley) and his colleagues of the Derby Gas Company to know how fitly it crowned and finished a glorious week. Never has there been an Institution meeting which has exceeded, though some have equalled, the success of this one. During it, the interests of the industry have been distinctly advanced.

The President on Our Opportunities and Requisite Work.

PERSPICACITY and lucid statement were characteristics of the Presidential Address; and there was a continuity of thought through it which carried us from basic facts as to the position and importance of the industry in the work and economics of the times on to our duty in making the maximum use of our potentialities by insistent, persevering research and by the application of the findings as we proceed, and as opportunity serves. There is good ground for such counsel. We realize that there is a strong movement which if successful would—providing the expectations were fulfilled—place in the hands of our competitors advantages which it is not proposed to confer upon the gas industry; and, truth to tell, we would rather be without them. But that movement should be a blessing in disguise in urging us to do everything possible to strengthen our hands for the more acute competition which threatens. For our own part (while doing all possible to further resistance to the proposals of the Government in regard to the electricity supply industry as being unjust if national money is used for helping one competing industry as against another, and as showing no national advantage—indeed, the reverse in respect of the utilization of our coal resources), we have confidence that the gas industry possesses such vitality and possibilities if developed with set purpose that the situation in those spheres in which gas supply has proved advantages will be, so far as electricity supply is concerned, considerably worsened. That confidence is reinforced by the address of Mr. Bell, which shows conclusively that, if the Government are going to render financial assistance to the electricity industry, they are not only backing the wrong horse, but they are doing something that is wrong nationally and in principle.

The address shows, as does every part of the proceedings at the annual meeting, the largely increased strength of the industry through the developments of recent years. Those developments have given us new foundations. The problems of to-day are far greater than those of yesterday; and each development produces fresh problems. Right in the forefront of the address, the President solicits the continued enthusiastic activity of members in promoting the advancement of the industry by applying themselves to the solution of the many problems on which success depends. In other words, what he urges us to do is to use our existing strength, and leave nothing undone, in the way of research and education, to develop the industry's resources so that we may maintain our supremacy, despite any political errors that may be made. We place on equal planes both research and the education of men for the industry. The two are united and interactive; and, holding that view, we welcome the foreshadowing in the address of the probability that membership of the Institution will in the near future be by examination. If that comes to pass, knowledge being the dominant essential for membership, we see no reason why there should be any limitations of an official order placed upon membership, though in the first stages, at any rate, we do see reasons for examinations being graded in respect of men managing works of the lower magnitude. It is the expansion of our industry, its services, and the enlargement of our outlook, together with the more active competition through the development of the resources of our competitors, which makes more forceful the constant reminder of the need and importance of research and adequate and specialized educational training.

The President gives statistics showing the progress of gas supply in this country and America. The comparison which this affords is extremely interesting. Our progress in this country, with an investigation of the lines along which it has been made, is directive as to the future. We have reached a consumption of gas in statutory supply areas, taking the latest available data, of 282 thousand million cubic feet a year, with about 8½ million consumers. But in America (despite the constant references of our electrical friends to the wonderful accomplishments of electricity in the States), they had in 1923 a consumption of 370 thousand million c.ft. of manufactured gas, and 760 thousand million c.ft. of natural gas (together 1130 thousand million c.ft.) with 9½ million consumers—that is to say, only a million consumers more than we had, but a consumption which dwarfs ours completely. And in view of the higher calorific values of manufactured gas in the States and the high calorific value of the natural gas, the thermal disparity is much greater. In America, as here, large strides are being made in the applications of gas for domestic heating apparatus, cookers, water heating, and gas-fires; but it is to industrial work that a large proportion of the huge consumption of both manufactured and natural gas is applied. The availability of natural gas in the States taught industry there the value of gaseous heating; and now that there is a dwindling of the yields of that gas, the manufacturers are anxiously looking round for ways and means of producing not only the necessary compensation, but more gas. And the prospect is that it will be done by the gasification at the collieries of low-grade fuel, with transmission through the natural gas systems—perhaps at first in conjunction with the natural brand. The fact that the natural gas is giving out in some districts indicates what will happen in others; and we therefore look for a prodigious increase in manufactured gas in the States for industrial purposes. In this country we have not had the advantage of natural gas supplying thermal energy at low prices; and the education of our manufacturers as to the advantages of furnace heating, steam raising, and other processes by gas has consequently been a slower process. Now the British Commercial Gas Association have on record a list of more than 4000 trades in which gas is used with an average of seven processes in each. This, as the President says, indicates the immense field there is for future development and enterprise. Within its limits, Derby illustrates what a studied consideration of the industrial business can achieve; but we are bound to say that Mr. Bell, pleased as he must be with what has been accomplished there, will not be satisfied until a still greater proportion of the growing output is for industrial purposes. In the past decade there has been an increase in the industrial load at Derby of 128 p.ct.; the total industrial consumption last year being 326 million c.ft., or 21 p.ct. of the total output. There gas-engines have for over twenty years been fixed on hire-purchase terms, and now the progressive Board have decided to let them out on simple hire. We admire the enterprise and the results.

The fact of the matter is that the gas industry in this country, proud as it is of its achievements, is only just awaking to its great potentialities; and thus it is that energy has to be directed to ascertain how best to meet the requirements that have opened up before us—domestic and industrial. When we survey, as the President leads us to do, the enormous field there is in domestic heating in several directions, and the untold scope there is in industry for our primary commodity, there is satisfaction. But satisfaction alone will not help along the development which will suppress the waste that is going on to-day through the immolation on the altar of crudeness of a vast tonnage of coal annually—representing a loss, the President calculates, of £30,000,000 a year— nor will it without work in other directions teach the manufacturer the economic advantages of gas heating through the employment of such a flexible and tractable fuel as gas. As the President shows, electricity cannot offer such value for money as gas for any ordinary heating purpose. The efficiencies he gives for gas are easily upheld in daily practice; and our electrical friends cannot dispute the fairness of those he supplies for electricity, for the simple reason that they are determinations from actual tests. Then, further, the industry has the liberty conferred by the Gas Regulation Act of adopting the most economic calorific value for gas in relation to local circumstances. That liberty we must not forego, because we do not know what the future has in store. On that point, the President thinks there is much to be said for a uniform calorific standard of (say) 500 B.Th.U. for the whole country.

That is a view—we think the only one in the address—in which we disagree with the President. We do not think a universal calorific value would do much to reduce manufacturers' costs, seeing that the difference between one calorific value and another (within the limits of practice to-day), taking into account too the difference of pressure and specific gravity, is more a matter of adjustment than of structural variation. It is true that 500 B.Th.U. would simplify the work of the clerical department, and enable consumers readily to convert volume into therms. It is true too that there has been a marked tendency on current economic grounds to return from lower declared values to 500 B.Th.U. or something approaching. But do not let us talk of what would be the reactionary step of restoring uniform value. In view of the unknown future, the flexibility gained by the Act must be maintained; and the address supplies other reasons why it should be, and why gas making in this country should not be again stereotyped. The President gives representative thermal efficiencies for the various gas-making systems; but he himself points out that those efficiencies are subject to the variations that availability of different grades of coal brings about, and which necessitates the placing of economic efficiency as shown by the net cost per therm into the holder before the thermal efficiency of the process, important as this is in securing the maximum result from the process in the circumstances of its use. There we have a reason, even in current conditions, against returning to a uniform calorific value throughout the country. Our processes, too, may undergo considerable changes before long, by, for example, altering the characteristics of retort charges to secure more rapid heat transmission, and better physical qualities in coke. That may hasten the adoption of internal heating and the displacement of current practices. The President says we are on the eve of great developments in the utilization of gas; and it is fortunate to be able to believe that we have not reached the end of important developments in our carbonizing operations. Moreover—and the President makes a strong point of this—investigations in America with natural gas of 1100 B.Th.U. per c.ft. and manufactured gas of from 725 to 500 B.Th.U., and the work of the Research Committee of the Institution and the Leeds University with gas between 500 and 240 B.Th.U., "indicate that the relative usefulness of various gases for ordinary purposes is directly proportional to their heating value, and that there is no advantage in gas of the lower heating values, but rather the reverse for gases of low calorific value with high inert content." The opposite lesson is also indicated—that there is no advantage (other than in the volume of gas to be distributed) in the higher heating values compared with the lower ones, provided the inert content is not abnormal, and there is consistency in the gas and conditions of supply. On all material points the evidence shows the wisdom of not giving up, by voluntarily returning to uniformity of calorific value throughout the country, the liberty conferred upon the industry by the Act. Under it every individual who agrees with a 500 B.Th.U. standard in his current circumstances can adopt it.

However, this all shows that the address points to the immense scope for service that lies before the industry; it indicates the directions of greatest possible development; there is the liberty conferred by the Gas Regulation Act; there is the important fact that we can through that liberty alter our practices to suit changing and uncontrollable economic conditions; and there is the fact that in use the efficiencies of gases of different calorific values are approximately the same. In those conditions there is plenty of inducement and encouragement to search and to work for still greater progress in our manufacturing systems. At the moment we appear to have got to a point where the over-all efficiencies of various processes do not show any notable variation; and though some processes give more gas and less residual products than others, the net cost per therm into the holder (combined with other considerations) has not been sufficiently seductive to induce gas engineers to make those systems their main sources of supply, but, save in restricted circumstances, they have continued to occupy the positions of auxiliaries. While talking of this matter, we must congratulate the President regarding his statement as to net cost of gas last year into the holders at the Litchurch Works of the Derby Gas Company. Carbonizing cheaper coals and smalls, the over-all thermal efficiency was for a mixed gas 70·86 p.ct.; and the average cost for coal, coke, and oil was 4·48d., and less residuals 3·34d., or 1·14d. net per therm for a gas of 503·8 B.Th.U. The oil used was only 0·0428 gallon per 1000 c.ft. to enable the use of larger percentages of C.W.G. to meet sudden increases in the demand. Of a total make of 1362⅛ million c.ft., 20·93 p.ct. was blue or slightly carburetted water gas. In this connection, the President emphasizes the invaluable aid that the auxiliary types of plant are to the gas manufacturer, both in promoting as occasion demands better economic conditions, and in meeting peak loads or needs in times of emergency.

This brings us back to the insistent note which we find in the address as to utilizing in every possible way the services of research, to point the directions in which we can, with still better effect, enter into the vast open territories that lie before the industry. Research is the most direct course to development. The President, as an old gas practitioner, knows it; and he cannot give too much praise to the work that has been done by the Research Committee of the Institution and the Leeds University, and by the Fuel Research Board. They have supplied knowledge which has removed defects, and pointed the ways to a greater certainty of result. They have also shown present limitations, and the advantages to progress that we possess in the efficiencies of utilization of our heating product. We have reached a state of knowledge at which it may be said that with present plant and materials we are getting approximately maximum results where there is careful supervision and control. Let us, however, regard that in looking to the future as all fundamental. What is there beyond? Research and time alone can inform us. It is to that the Presidential Address leads us. And if we merely direct the attention of readers to the sapient views of Mr. Bell on the subject of working to enlarge the field of coke utilization, and to his protest against Government assistance to the electricity industry, and his plea for an inquiry covering a larger field than electrical power, it is because the matters already dealt with provide the main theme in an address which gives us abundant reason for pushing forward in the attempt to gain more and more strength and power for meeting the demands that lie before.

Bitumen and Electricity.

NATURALLY, with a large assembly in London last week of those chiefly executively responsible for the technical and commercial interests of the gas industry, a great deal has been heard of the matters upon which the industry is in unison acting on the defensive. The present position is that the use of gas is increasing in volume, especially for domestic heating and industrial purposes. The Government, on the other hand, are proposing to "assist" the electricity industry to co-ordinate its generating procedure and to expand its means of distribution. Why the Government should do this, and not leave it to the industry itself, is not at all clear, either on rational or national grounds. The secondary products of coal carbonization have suffered a set-back; and yet Sir Henry Maybury, who began the ride to his present distinguished position over tar-surfaced roads, is now—according to newspaper reports—decrying his best friend tar for the purpose of road work, and advocating imported bitumen in preference to the home-produced material. Many people who know fully the long history and the acclaimed and acknowledged advantages of tar for road purposes, originally demonstrated on the roads of Kent when Sir Henry had charge of them, are asking why there is this change of front; and they are getting inquisitive. Coke, also, is not yielding as it should do; and among a combination of several causes which has produced the set-back, is the one that the coke-oven industry is increasing its energies in producing coke suitable for purposes for which gas coke is employed. There is sulphate of ammonia, too, which has now to meet the condition of increased output through the enormous supplement of

synthetic nitrogen. But the new competition that has to be faced by the two latter secondary products is of an order which must be combatted by the exercise of ingenuity and energy within the gas industry itself. In regard to coke, we have the advantages of local situation and better distribution facilities than the coke-oven people; and it is a question of adding to that a proper preparation of coke and improving the quality as far as possible, with the view of making it not only as acceptable, but preferable in the region of its production.

The questions of tar and bitumen and electricity are altogether different ones. It is not a matter of improvement in the quality of our products or trading methods; it is, to put it bluntly, a question of dealing with influences in high places. Last week there was much private discussion among gas men as to the lately developed advocacy of bitumen in place of prepared tar for road work; and the matter is not going to be allowed to rest where it is. The Government are busy, under the Safeguarding of Industries Act, protecting various industries. Some of the Labour members—strong anti-protectionists that they are according to party creed—are beginning to talk of the productions of our own workers being favoured instead of those of foreign workshops. Twenty of them voted for Imperial Preference last Friday; and there would have been more had they been in the House at the time. However, as to safeguarding our own industries and productions, there is great unemployment in the land; and our politicians are seeking ways of realizing relief from the financial burden and loss that this entails. The miners are seeking to improve their conditions. Tar is a commodity produced from coal in British works, by British workmen, plant, and capital; bitumen is an imported article. If he is reported correctly, Sir Henry Maybury is turning his back on British tar for British roads, and is recommending bitumen. It would be of interest to know whether there is any misunderstanding. In the presence of the President of the Board of Trade (Sir Philip Cunliffe-Lister), at a luncheon last week, Mr. D. Milne Watson stated that Sir Henry was reported to have said that tar would stick to anything except the road. To say this of a British product, and to attempt to persuade people to use imported bitumen for road-making purposes, Mr. Milne Watson emphatically described as a "scandal." If Sir Henry has not been misreported, then he has to explain to people who years ago admired and appreciated the roads of Kent, why it is that the tar stuck to the roads very well then, and why the Mr. Maybury of those days issued many laudatory reports concerning its advantages to the users of roads and its preservative qualities which were of benefit to those responsible for the upkeep of the surfaces—reports and papers such as the one before the International Roads Congress in Paris in 1908. [See "JOURNAL" for Oct. 27, 1908, p. 266.] The President of the Board of Trade knows the roads of Kent, and so do thousands of other people; and at the luncheon referred to, he put the question as to whether it is not a fact that the roads of Kent, which in past years set the standard for road construction throughout the country, did not obtain their pre-eminence by the use of tar, and not of bitumen. The reply came from Dr. Charles Carpenter that, when Sir Henry Maybury was an official of the county authority, and was responsible for the Kentish road system, tar was used as the surfacing material, and the roads were a model which should have been generally followed. Thousands upon thousands of the users of those roads can give similar testimony; and therefore it is fair to ask, Why this *volte-face* on the part of Sir Henry, who was the pioneer in this work? That is a question which sooner or later must be answered, as well as the one which will be put by those people who are disinterested in the materials used, but who are well acquainted with the roads of Kent and other counties, as to why years of good experience with tar have come to an end with the exploitation of imported bitumen for the same purpose. If it is a question of fisheries, then the roads alongside such rivers and streams are of comparatively short length compared with the enormous aggregate length of other roads; and tar can now be prepared (as the South Metropolitan Company are demonstrating at Wembley) so that washings from it are perfectly innocuous. There will be general agreement with Sir Philip Cunliffe-Lister that, having regard to the general state of trade, and the fact that industry is working on a diminishing margin of profit, it is of vital importance that use should be made for home requirements of commodities made in this country rather than of imported materials—due regard being had to the national interests involved. In the employment of any product of coal, Sir Philip also remarked, home industry is helped, and more money is provided to found new markets. What was actually said on the subject at the luncheon will be found reported elsewhere.

Tar and bitumen, however, were not the only topics privately and publicly discussed during the week. There were the Government's proposals as to electricity. On the opening day of the meeting, there was a deputation to the Ministry of Transport (headed by Mr. D. Milne Watson) representative of practically the whole of the company and municipal gas undertakings of the United Kingdom. The case of the gas industry as to the proposals was laid before Colonel Ashley, Sir Burton Chadwick, and Colonel Moore-Brabazon; and Colonel Ashley undertook to bear in mind the representations made to him, and to see that they had due consideration. If "due consideration" is given to them, the Government must see that there is no need for their intervention in the national interests; that any financial assistance to the electricity industry is unnecessary, and would, in any case, be unfair to a competing industry, which has developed itself by its own exertions and from its own resources; and that the problem in hand is one which should receive investigation from the source of power and heat—coal—in order that the error should not be made of giving Government support to any project which would mean a wasteful utilization of our principal natural and national asset. In his address at the meeting of the Institution, the President also made out a strong case against Government assistance to the electricity industry. The matter was again raised by Mr. Milne Watson at the luncheon at which Sir Philip Cunliffe-Lister was present. Sir Philip urged that the gas industry should not spoil their case by placing their claims too high, and suggested that, if there was some particular way in connection with an industry in which the Government could assist to bring about better conditions in the national interests, it was a matter for their consideration. We know that the Board of Trade have deeply at heart the interests of the gas industry. There is no question about that; but no one in the industry desires that the Board should make any move for preferential treatment to it, beyond enabling it, through its own resources, to provide the best possible public service. But we do submit, with all deference to Sir Philip, that it is not the gas industry that is placing claims too high, but (we judge from speeches by Ministers and statements in Parliament) it is the Government who are doing so through misconceptions and mistakes due to the want of fundamental, elementary, and comparative knowledge of this particular subject. The inquiries of successive Governments into this matter have been, *ab initio*, too narrow to place them in possession of that fundamental, elementary, and comparative knowledge which would have enabled them to arrive at right conclusions. There are men in the electricity supply industry who do not want Government assistance or interference; there are others who are laughing up their sleeves at the prospect of the Government—in sheer innocence—supplying "assistance" from the national funds to help to build-up an industry which is already enjoying a considerable measure of prosperity. If there is anything in the proposals of the Government which competent electrical men consider would be of advantage, does the Government think that, without having recourse to the moneys of the taxpayers, the electricity industry would not find ways and means of adopting them? The industry is not in an indigent condition. The truth lies in the contrary direction. If the Government require more evidence, it is at hand; and, in seeking it, the addresses which Mr. Milne Watson has recently delivered will be considerable enlightening aids.

The gas industry cannot afford to sit still while such questions as those to which we have referred are developing. It would be of little use to raise a protesting voice

after the mischief had been done. The members of the Government could properly say: "Why did you not speak before?" and they would be justified in ignoring an industry which had allowed things to proceed without taking defensive action. In both the matters of bitumen and electricity, the gas industry is fighting not only in its own interests, but in those of the nation. That it is doing so can be proved up to the hilt; and, if that is true (and we know it is), then the industry is not placing its claims any too high.

Chemical Manufacturers and the Gas Industry.

The chemical manufacturers have, through Mr. J. L. Deuchar, the Secretary of the Castner-Kellner Alkali Company, Ltd., pursued the Gas Light and Coke Company through the Courts right to the House of Lords, in connection with their manufacture of caustic soda for converting naphthalene into beta naphthol. The importance which the chemical manufacturers attached to the case is attested by their action in taking it to the House of Lords. The fact that in every Court the Gas Light and Coke Company won, is significant of the strength of their right. We congratulate them on the result of a case which was a deliberate attempt on the part of the chemical manufacturers further to control the liberties of the gas industry. In the dismissal of the appeal, the Lord Chancellor, and Lords Dunedin, Atkinson, Sumner, and Buckmaster were unanimous. The chemical manufacturers have—at a price—gained the knowledge that they cannot be permitted to rule the economies of another industry.

Gas Prohibition by Local Authorities.

We are pleased to note that a point we have previously raised—on a recent occasion in connection with the Newport (Mon.) Corporation Bill (*ante*, pp. 444, 719)—has also been receiving the attention of the National Gas Council. It is becoming a common practice for local authorities possessing electricity undertakings to insert in tenancy agreements, in respect of houses built by them as representing the ratepayers, a condition to the effect that gas shall not be used for specific purposes. The question has been discussed by the "N.G.C." as to the position that would arise should a tenant apply for a supply of gas, as he or she is entitled to do under the Gas Acts. Gas suppliers have no power to refuse, seeing that the law stands above conditions inserted in tenancy agreements by a municipal authority. Not long ago a local authority was prevented from supplying electricity to a house which had been wired by non-union labour, by a threat that, if they did so, the trade union employees at the generating station would be called out. An action by the tenant against the local authority resulted in a decision that they were bound to supply under the General Act. The "N.G.C." considers that the matter is of such importance to the whole industry that Counsel's opinion should be taken. It will be interesting to see the result.

The Coke Competition.

Papers for this world-wide competition are beginning to arrive. There is now less than a fortnight before the competition will close. Careful attention should be given by competitors to the conditions as to name and address being enclosed in a sealed envelope bearing outside the *nom de plume* which appears on the paper. Those contributors who are competing in different sections should send the contributions in separate envelopes. These requirements, with several others, were plainly set forth in the issue of the "JOURNAL" for Feb. 18.

At Wembley.

With so many gas engineers and their wives in London last week, although there was no set visit, many of them found their way to Wembley, and inspected the Gas Exhibit and what is being done near by to develop the interests of coke and tar. Those who mentioned to us their visits expressed complete satisfaction with what they had seen.

How to Save the Coal Industry!

Low-Temperature Carbonisation, Ltd., have issued a little booklet giving extracts from speeches and writings from various non-technical sources eulogizing low-temperature carbonization for the production of oil, and included are figures from the Fuel Research Board's report on the results of tests made at the Barnsley plant. It is not stated in the booklet that the Board are not yet satisfied as to the commercial success of low-temperature carbonization, and that they are well aware the products would be exposed to violent market fluctuations. But information is supplied as to the large imports of oil, and regarding their enormous value. The prediction is made that at the present rate of increased consumption of oil, "England's greatest industry—the coal trade—on which the supremacy of Great Britain was built, approaches its doom." How terrible! The only solution of the problem, according to the booklet, is low-temperature carbonization. It seems to be taking the system a long time to make strides in its work of salvation for the coal industry. Mention is made of what is going to be done when that 1000-ton-a-day plant at Nottingham is at work. Not much has been heard about this plant lately. Has its construction been started yet? And has the Company obtained the capital for it? No doubt the coal industry will be gratified to learn that Low-Temperature Carbonisation, Ltd., is willing and waiting to save it.

Coal Mines Inquiry.

There have been further sittings of the Sub-Committee of coal owners' and miners' representatives to consider the causes of the depression in the industry, and to explore how economies in production can be effected. The matter is approaching a head; and to-day or to-morrow a very interesting stage will no doubt be reached, and probably further developments will take place next week. The miners' leaders we believe are wise enough to see that the remedies must be internal, for nothing of an external nature can convert the industry from its state of depression to prosperity. One of the main causes of the cloud overhanging the industry is that people abroad can buy coal at a cheaper rate from other countries, and the reason for the dearness of our coal is that the costs of production are too high. That is the position in a nutshell. No one wants the earning power of the miners to be reduced; but the solution of the trouble can only be a greater production for the money earned, so that the costs per ton will be lowered. Neither side has yet formulated proposals; but there are those among the miners' leaders who say they will not accept any suggestion as to a longer working day. Supposing there is no other solution, are the miners' leaders going to allow things to go from bad to worse?

"B.C.G.A." Annual Conference.

In order that those intending to be present may keep the dates open, Mr. J. C. Walker (the Secretary and Assistant Manager) notifies that the British Commercial Gas Association's Fourteenth Annual Conference and General Meeting will be held in Plymouth on Monday, Tuesday, and Wednesday, Oct. 19 to 21. As hotel accommodation in Plymouth is very limited, and as it is anticipated that there will be a large attendance of members, the earliest possible applications for rooms is advised.

Irish Association of Gas Managers.

An excellent programme is being arranged for this year's meeting of the Irish Association of Gas Managers, which, it has been learned from the energetic Hon. Secretary, Mr. George Airth, of Dundalk (who was in London last week attending the annual meeting of the Institution of Gas Engineers), is to be held in Belfast on September 15, 16, and 17. This is a month later than the date usually fixed; but it may be explained that it is to take place in conjunction with meetings of the Irish Section of the National Gas Council and of the "B.C.G.A." There is also, at the same time, to be a big gas exhibition in Belfast. A feature of the meeting (of which full particulars will be announced later) will be an excursion to Portrush and the Giant's Causeway.

The Bournemouth Group Photograph.—Copies of the large group photograph, taken on the occasion of the visit of the Southern Association to Bournemouth, can be obtained of the photographer—Mr. J. Reade, 58, Holdenhurst Road, Bournemouth. The price per copy, including postage, is 5s.

Correction in Southern Association Report.—We regret the incorporation of an error in our report of the Summer Meeting of the Association in Bournemouth. Mr. William Cash, at the luncheon, said—*not* as given by us at the end of his speech—that he was proud that the Engineers of the Barnet, Croydon, and Worthing undertakings, of which Companies he is also Chairman, were present.

PERSONAL.

The Burnley Gas Committee have recommended the appointment of Mr. W. H. Cooper, of Harrogate, to the position of Manager of the Corporation's gas showroom.

Mr. G. F. Horsley, an original member of the Institution of Chemical Engineers, has been appointed to the post of Director of Research for the Nitrate Producers' Association of Valparaiso. The Institution of Chemical Engineers have recently successfully started an Appointments Bureau; and it is hoped that all those who have appointments to fill will place particulars of them on the register of the Bureau at Abbey House, Westminster, S.W. 1.

OBITUARY.

Sir Wilson Mappin, Bart., J.P., of Thornbury, Sheffield, who died on Monday of last week, after a long illness, at the age of 77, was intimately connected with the Sheffield Gas Company for a long period. Elected a Director in 1885, in succession to Mr. Horace Walker, he became Deputy Chairman in 1891; and in 1908, when his father resigned the chairmanship, which he had held for 35½ years, Sir Wilson Mappin was chosen for the vacant office. He devoted a great deal of his time to the concerns of the Company—not only taking his part in the Directors' meetings, but being regular in his attendance at the offices, and diligent in acquiring a detailed knowledge of the extensive business of the Company. In March, 1918, Sir Wilson resigned his position as Chairman of the Company; and his resignation was received with keen regret by his co-Directors and by the staff, by whom he was held in high esteem.

After a short illness, the death took place, on Tuesday of last week, at West Norwood, of Mr. William Joseph Dibdin, F.I.C., F.C.S. He was 74 years of age, and used at one time to be frequently before the gas industry, more particularly in connection with his extensive investigations in the subject of photometry. Indeed, at one time his books were the only ones which dealt with this matter in a really complete manner. He was also prominent in connection with standard burner questions when they came before Parliament—naturally on the side of the London County Council, to which body he acted as Chemist and Superintending Gas Examiner for a period of fifteen years. On his retirement from this position towards the end of 1897, presentations by the officers and staff of his department testified to the esteem in which he was held by them. His successor was Dr. F. Clowes, who was also well known to readers of the "Journal" in connection with his investigations on the detection of dangerous proportions of explosive mixtures of combustible gases with air, on which subject he lectured at the meeting of the Gas Institute in 1896.

FORTHCOMING ENGAGEMENTS.

[*Secretaries of Gas and Kindred Organizations are asked to assist in making this diary of events as complete and useful as possible by sending the earliest intimation of all meetings.*]

June 19.—Industrial Gas Salesmen's Circle.—Meeting at the Council House, Birmingham. Inspection will be made of the industrial gas demonstration rooms and research laboratories of the Birmingham Gas Department, and visits will be paid to the Windsor Street heat treatment shops, and to the works of the Moss Gear Company, Ltd.

June 20.—London and Southern District Junior Gas Association.—Visit to the Cambridge Gas-Works.

June 24.—Southern Association of Gas Engineers and Managers (Eastern District).—Meeting at the Institution of Gas Engineers, No. 28, Grosvenor Gardens, S.W. 1, at 2.30.

June 22-24.—Institution of Heating and Ventilating Engineers.—Summer Meeting at Birmingham.

June 30.—Last Day for Coke Competition Papers.

July 9.—Coke Oven Managers' Association (Midland Section).—Visit to the works of Messrs. Stainby and Lyon, of Knottingley.

July 20-25.—Royal Sanitary Institute.—Congress at Edinburgh. H.R.H. the Duke of York has accepted the Hon. Presidentship of this Congress, at which Sir John Gilmour, Bart., Secretary for Scotland, will preside, and deliver the Inaugural Address. A health exhibition is to be held in connection with the Congress.

Sept. 15-17.—Irish Association of Gas Managers.—Annual Meeting in Belfast.

Oct. 19-21.—British Commercial Gas Association.—Annual Conference and General Meeting in Plymouth.

NATIONAL GAS COUNCIL.

Meeting of Central Executive Board.

The Central Executive Board of the National Gas Council met on Monday, June 8, at No. 28, Grosvenor Gardens. Alderman F. S. Phillips was voted to the chair, pending the election of a Chairman for the ensuing year.

Election of Chairman and Vice-Chairmen.

Mr. D. Milne Watson was unanimously re-elected Chairman for another year, and thereupon took the chair.

The four retiring Vice-Chairmen—viz., Alderman F. S. Phillips, Mr. Wm. Cash, Mr. J. H. Ellis, and Mr. F. H. Jones—were also unanimously re-elected.

Rating and Valuation Bill.

It was reported that the Rating Committee appointed by the Central Executive Board had considered the new Bill introduced by the Government, and had come to the conclusion that, save for one or two matters which it was proposed to discuss with the Ministry of Health, the gas industry saw no objection to the Bill.

Departmental Committee in Connection with the Law on Diversion of Highways.

It was reported that representations had been made to the Home Secretary as to the desirability of public utility undertakings being represented upon the above Committee. The Home Secretary had, however, replied that, as the Committee had now held several meetings, he could not see his way to agree to any further representatives being appointed to the Committee, but he promised to see that particular attention was given to the evidence of public utility associations.

Mr. Ogilvie was empowered by the Central Executive Board to give evidence on behalf of the Council before the Committee in question.

Mains in Public Highways.

It was reported that, despite the fact that a conference was proceeding between public utility associations and highway authorities, including representatives of county councils, upon the question of mains and cables in highways, the Northampton County Council were proposing to oppose the Draft Special Order of the Northampton Gas Light Company for the purpose of inserting a drastic protective clause in favour of the County Council. It was agreed that assistance should be accorded to the undertaking in certain directions.

Local Authorities and Gas Prohibition.

It was reported that several gas undertakings were confronted with the difficulty that their municipal authority had inserted a provision in tenancy agreements that their tenants should not use gas for certain specific purposes in houses belonging to such authorities. The question was discussed as to the position of the gas undertaking should one of the tenants give an order for the installation of gas. It was agreed that this was a matter of importance to the whole of the industry, and that Counsel's opinion should be taken thereon.

Analysis of Refractory Materials.

In the "Chemiker-Zeitung" for May 16, H. Schilling gives the following method of analyzing refractory materials, which allows the rapid estimation of the iron and alumina contents: One gramme of the finely powdered and sieved material is ignited in a platinum crucible to determine the loss on ignition. The residue when cold is moistened with distilled water, about 20 drops of concentrated sulphuric acid are added, and then the requisite amount of hydrofluoric acid. The contents of the crucible are stirred gently by shaking the crucible, which is then heated, at first gently and then strongly, over the blowpipe until all fuming ceases. After cooling, the fusion mixture is added, and the contents of the crucible gently fused. The mass is then dissolved in hydrochloric acid, avoiding any excess so far as possible, and precipitated with ammonia at the boil. The precipitate, together with the filter paper, is transferred, without washing, to the porcelain dish in which the original precipitation was conducted, and dissolved again in a few c.c. of strong HCl, the operation being conducted on the steam bath with continuous stirring. The filter paper disintegrates into its fibres. The solution is diluted with distilled water, precipitated afresh with ammonia, and washed until the washings are free from chlorine. The precipitate is then ignited in a platinum crucible, treated with a small quantity of HF and H_2SO_4, and ignited in the blowpipe until all traces of fuming cease. Subsequent weighing gives the content of the refractory material in iron oxide, alumina, and titanic acid. The iron content can be estimated by dissolving the residue in HCl, filtering off the small quantity of TiO, which may be present, and titrating the iron by any of the standard methods.

INSTITUTION OF GAS ENGINEERS.

ANNUAL MEETING,

AT THE

INSTITUTION OF CIVIL ENGINEERS, GREAT GEORGE STREET, S.W.

JUNE 9, 10, and 11, 1925.

President: J. FERGUSON BELL, Esq., M.Inst.C.E.

REVIEW OF THE PROCEEDINGS.

[For Full Report see p. 854.]

THE radiant morning of Tuesday of last week greeted 600 to 700 visitors to London for the Annual Meeting of the Institution; and thenceforward throughout the day and the week, the sun did its best to make things cheerful. The sun and shade temperatures on the opening day of the meeting were something to which we have grown unaccustomed; at one part of the following day it was hotter still—shade temperatures of 80° to 83° being registered in London. But no one complained; everybody merely said it was hot. There seemed to have been a conspiracy of silence about the discomforts of the intense heat; probably because there has been complaint enough about the want of sun, and when it came in bulk supply, it would have been ungrateful to say anything about it which might have appeared at all disparaging. Men come and men go; but nevertheless it seems to have become a tradition among gas men that—especially on the opening day of the Annual Conference—they should stay outside the meeting place for the purpose of greeting their friends. It has its good features and its bad. We like it because it gives an opportunity for a grip of the hand and a friendly word before getting into the serious atmosphere of the meeting room. But, on the other hand, it is not courteous to the President to let this freedom and pleasure run beyond the hour appointed for the start of the meeting. However, the Great Hall of the Institution of Civil Engineers was well filled by the time all had assembled—in fact, we doubt whether there has been a meeting numerically larger; and this is not surprising, for the membership has grown to about 1100. The Great Hall is commodious, and the hospitable accommodation afforded by the President and Council of the "Civils" is much appreciated. But many there were at the meetings who wished that that beautiful hall had better acoustic properties.

MR. J. FERGUSON BELL, J.P., M.Inst.C.E.

From general topics to others. The President (Mr. J. Ferguson Bell, M.Inst.C.E.) was prompt to time; and, despite the heat, he looked the coolest man in the whole assembly. It was a remarkable gathering that met the eye on the platform. There was not only the Senior Vice-President (Mr. C. F. Botley), the Ex-President (Mr. Samuel Tagg), the Hon. Secretary (Mr. W. E. Price), the Secretary (Mr. Walter T. Dunn), and other officers and members of the Council, but there was the Right Hon. Sir Alfred Mond, Bart., M.P. (President of the Society of British Gas Industries), Mr. W. Woolley (Chairman of the Derby Gas Company), the President of the National Gas Council (Mr. D. Milne Watson), and many others who are prominent in the organized work of the industry. Also there were gentlemen representing the gas industries of France, Switzerland, Belgium, and Norway; even India, Australia, and the United States had representatives there. It was a gathering international in composition, and bringing to a centre workers from the far-placed parts of the British Empire. Later on there was further evidence of the oneness of the world's gas industry by the presentation of a paper by M. L. Rolland d'Estape, President of the Société Technique de l'Industrie du Gaz en France, which was read in English by M. Baril. Municipal activity was worthily represented by the Lord Mayor of Manchester (Alderman Fred J. West, C.B.E., M.Inst.C.E.), who as the bearer of an honoured name in our industry, himself a keen worker, and one who has won a distinguished place in civic life, was very heartily received. There was also present the Mayor of Halifax (Alderman Waddington). Mr. H. C. Honey, the Director of Gas Administration at the Board of Trade, was another important guest.

A Welcome—Industry and Unemployment.

Some formal business was transacted; and then the President gave a warm welcome to the distinguished visitors and to the delegates from the Continent and from further overseas. What he said was endorsed by the hundreds of members, and so heartily that there was no room for doubt as to the complete and unanimous sincerity of the welcome. And as he rose to respond each speaker had a reception which was a vivid re-endorsement. Mr. Woolley responded, and so did Sir Alfred Mond and M. H. Zollikofer, who rendered as interpreter excellent service during the morning's proceedings. Sir Alfred Mond, probably under a misapprehension as to the time at disposal, spoke at length on the position of industry in relation to unemployment. Sir Alfred believes that the cause of depression in industry is the discrepancy between the cost of production and the money available for the purchase of goods. Can the gap between the two be bridged? Can we "marry" the

national expenditure on unemployment to the costs of production in such a way as to permit of the making of goods at a price which the consumer can pay? He thinks we can; and he believes the scheme he has put forward will do it. In other words, he considers that it would be far better for the country to spend part of the money now distributed in unemployment pay on bringing our products to a competitive price, so as to give the unemployed employment, than to continue to spend such large sums per annum on unemployment, and leave idle so much factory and man power and capital. Sir Alfred finds that the Swiss have anticipated him by three years by establishing a similar scheme in their watch-making industry; and the results he has suggested have been realized in Switzerland. The gas industry is deeply concerned in this question of helping trade to a greater activity, because it has a considerable business with many industries, and still spacious room for its growth to mutual advantage.

Extension of the Roll of Hon. Members.

There is one thing the members of the Institution always like to do, and, when they are agreed upon it, they do it enthusiastically. That is to honour those who have earned by good work their regard in the industry. The men whom they have honoured on this occasion are not only noted for good work, but their personal qualities have endeared them to professional gas men. First that doyen in the British gas profession (Mr. Charles Hunt) was placed upon the roll of honorary members. There is no need to extol his work and his virtues. They are recorded in the pages of the history of the progress of the industry during much more than half-a-century. Then the Rt. Hon. Alderman Fred J. West, C.B.E., M.Inst. C.E., the Lord Mayor of Manchester, had similar honour done him; and he keenly appreciated this act by the gas profession to one to whom service stands as a premier duty, as it did with his revered father. Then new links were forged with the co-workers of other countries by the election as hon. members of the Presidents of the American, Belgian, Canadian, French, Italian, Norwegian, Swedish, and Swiss Gas Associations.

Presentations.

Not many men have received the Birmingham Medal, and few, if any, can claim to have won it with greater distinction than Dr. Charles Carpenter. Upon him it has been conferred this year, by a unanimous vote of the Council, and, as we expected would be the case, the complete approval of the members of the Institution. He will prize it, as he feels and values the sincerity of the applause with which he was greeted as he went to the platform to receive the coveted (by gas men) symbol of their acknowledgment of eminent services and results of work—work showing originality and genius, and results marking progress. There was eloquence in the observations of the President; there was genuine feeling and thankfulness in the reply of Dr. Carpenter. There were also in his speech words formed from a life of study and observation of the gas-making industry which will be read with both interest and profit. They are reported on a later page. The charming reference of Dr. Carpenter to the work of his predecessor on the list of recipients of the Medal—Mr. W. Doig Gibb—was one of the many points which drew applause.

Then the "H. E. Jones" London Medal was presented to Mr. R. E. Gibson for his paper of last year on "The Construction of New Coal Gas Works at Garston, Liverpool." It was a splendid engineering contribution; and the members cordially endorsed the choice by the Council of Mr. Gibson as the recipient.

The winners of the Diplomas in Gas Engineering under the Institution Examination Scheme were then called individually to the platform to receive their certificates from the hands of the President. They represent the type of men the gas industry wants.

EARLY ON THE OPENING DAY.

Lord Moulton Memorial Fund.

Men like to pay tribute to the work of the great by establishing some form of memorial. It is not mere impulse or passing emotion which induces them to do this; but a real feeling of affection and admiration developed during the lifetime of the man. It is so with Lord Moulton, learned not only in the law, but in science; who in 1918—following his eminent services to the nation as Director-General of the High Explosives Department—was President of the Institution. Without a memorial, Lord Moulton's name would live through ages; but a memorial will tell future generations of how his contemporaries admired this brilliant man, who nevertheless was so self-sacrificing, delightfully unassuming, courteous, and approachable. A memorial to him is going to be established, and, with the full approbation of the members, the Institution will contribute £100.

The President's Address.

The members then settled down to listen to the President's Address. In this Mr. Bell gathered together those facts which give both gratification and encouragement regarding the progress of the industry, which in latter years

has been at a remarkable rate in respect of gas consumption, though we have had a set-back in regard to secondary products, the position of which the industry is seeking to restore. But in relation to gas, what are our prospects? Never were they of a more brilliant order. But though our horizon of opportunities has been enlarged, there will not be fullness of realization of the prospects without very definite work. That work is of a dual nature, and its parts must run on parallel lines. There must be proper education and training (this the industry is developing on good foundations), and there must continue to be persistent research into materials and processes with the view of increasing efficiencies and economies. But as the President points out, a full recognition is required of the importance of economic efficiency as well as of plant efficiency. It may at times be necessary to sacrifice some of the latter in order to secure the former—for example, by the purchase of cheaper small coals owing to their availability, though in other cases it might prove an advantage to pay slightly more for materials to secure a better efficiency, bearing in mind that carriage and labour are the same for good as for poor. Every case must be judged on local circumstances. Domestic heating and the industrial field are shown in the address to be promising lines for the development of business. Power experiences in Derby are dealt with; and it is plain that the President does not think the gas industry is doing all it might in that direction. The coke position, Government assistance to electricity, and much else is treated upon—well and practically. The deliverance gives the industry a good view of the current position, prospects, and problems, which in these times force themselves—and rightly so—to a leading place in our considerations. The address receives comment to greater extent in our editorial columns. It was listened to by the large audience with marked attention and interest, and was punctuated by applause. The appreciation of the members was faithfully expressed by Dr. Carpenter.

ANOTHER VIEW OUTSIDE THE INSTITUTION OF CIVIL ENGINEERS.

Annual Report and Accounts.

Evidently the members were quite satisfied with the annual report of the Council and the statement of accounts; for no sooner were these introduced, than they were agreed to, without comment.

The Education Scheme.

Always heartily received, Mr. F. W. Goodenough, the Chairman of the Education Scheme Advisory Committee, introduced the report on the past year's work and developments of the scheme. Taking first the report. It told of how the year had been one of steady, painstaking building. There is agreement with the Committee that, though progress has been slow, it will be more sure, because of the care that has been taken. The number of centres at which organized instruction in gas subjects is being given has increased from 11 to 21, with two other centres at which the earlier parts of approved courses are being taken. Further developments in this direction are in view. Of internal and external students combined, 110 applied for examination, against 60 in the first year. There were 30 others who applied, but were disqualified owing to lack of preliminary scientific training. That is significant, and shows the want of greater educational facilities, to provide which very earnest efforts are being made. Meanwhile, the students themselves can do something to repair the deficiency. There are many matters of an encouraging nature mentioned in the report, which need not be alluded to here, seeing that the document is prepared in pithy form, and so can be easily read. There has, among other things, been elimination of the overlapping of the Institution's Education Scheme and the work of the City and Guilds of London Institute. That is an excellent thing. The scheme has also been extended, so as to provide for all grades in the industry; and this has enlarged its effectiveness.

While this important work is in the hands of such "live wires" as the Chairman and members of the Committee, with Mr. Walter Hole as the Organizing Secretary, it will always be making progress; and whenever changes have to be made in the composition of the Committee, the good qualities in this regard of the members must be maintained in the new ones. The speech of Mr. Goodenough supplied the evidence that he would be better pleased if the average of students for examination was greater than 1 to 8 statutory undertakings in the kingdom, or only 1 to 14 of all the undertakings. Of course, this ratio will, as time passes, be improved upon. But it must be said that we are not convinced that all gas undertakings are doing their part in making provision for the thorough training of men for shouldering the responsibilities of the future. In some instances, there is a preference for this work to be done by others. That may be a compliment to the "others;" but to stand aloof from doing a part is not playing the game. There is a strong appeal in Mr. Goodenough's remarks in this respect; and we should like all gas administrators to read, mark, learn, inwardly digest, and act upon what he says. He also referred to the minor grouped courses which have been organized for those who require to equip themselves well for their work in life and for higher positions, but who do not aspire to the positions of professional men.

Aeration of Lighting Burners.

It will be remembered that Mr. J. W. Wood has for some time past been following-up the subject of the aeration of burners. At first the treatment was of a general character. Last year, however, a special study was made of burners used in heating appliances; and this year investigation has been carried out on the working of typical lighting burners. Perhaps the most outstanding result of the careful examination, which is recorded in the Thirteenth Report of the Research Sub-Committee of the Gas Investigation Committee, is that the amount of primary air injected by an ordinary lighting burner, working normally with a good illumination, is only about half the total air requirement. As Prof. Cobb points out, the significance of this is that effective illumination must depend largely on how the rest of the air is supplied. This shows what importance attaches to the accessory fittings which help to determine the manner in which the secondary air is supplied. The tests were conducted at pressures up to 4 in. W.G., mainly with gases of sp. gr. 0·49 and calorific value 460-470 B.Th.U. The average total theoretical air requirement per c.ft. of gas for combustion was 3·9 c.ft. It was found that there is a rapid increase of aeration with pressure up to 2·5 in. W.G., above which further increase is small. At this pressure the quantity of air injected in the inverted burners, when adjusted for best illumination, was 1·7 to 2·1 c.ft. per c.ft. of gas, though some burners were capable of injecting 2·5 c.ft. of air. The corresponding figures were higher for the upright burner. The air-port area provided when the shutter was fully open was in no case so small as to account for a low air-gas ratio; and the degree of aeration, it is interesting to note, was not proportional, even in the roughest sense, to the air-port area after a certain size had been exceeded. The heating-up of the lighting burner when in use materially reduced the quantity of air injected as compared with the performance on first lighting-up. This amounted at times to as much as a 40 p.ct. reduction. With an upright incandescent burner, the use of a chimney exerted no appreciable effect upon primary aeration; the improvement by its use being apparently due to more effective secondary aeration.

During the year Mr. Wood paid special attention to the determination of the specific gravity of gases. The determination by the effusimeter is apt to be erratic, while the making of a complete gas analysis is a tedious process. The gas engineer should have a means of determining density; and Mr. Wood has examined in detail Mr. Blackie's method (described in Technical Paper No. 5, Fuel Research Board), which, he says, when applied with proper precautions, is both accurate and comparatively rapid in working. It is capable of yielding results correct to ± 0·002 with ordinary town gas (sp. gr. 0·5). The report also includes a critical review of the methods of gas analysis adopted in the course of the investigations. It is interesting to note that all combustions were made over copper oxide in a silica tube. The chief advantages of this method are that a much larger volume of gas can be burned than by explosion, thus giving greater accuracy in measurement; combustion can be extended over sufficient time to ensure completion; there is no careful adjustment necessary to secure the right composition of an explosive mixture; and no auxiliary supplies or analyses of oxygen are required. The combustion tube is evacuated before and after combustion, using the gas burette as a mercury pump. This is only one of many valuable observations made by Mr. Wood in an appendix to the report.

Corbet-Woodall Experimental Gas Plant.

Readers of the "JOURNAL" will remember that in April, 1924, the Corbet-Woodall Experimental Gas Plant was inaugurated at the University of Leeds. A detailed description of the plant is given in the Fourteenth Report of the Research Sub-Committee of the Gas Investigation Committee. Dr. Parker and his assistants, Mr. Kerr and Dr. Monkhouse, have been occupied in getting the plant into a proper condition for carrying-out reliable experimental work, and in making preliminary tests. Many smaller fittings necessary in an installation intended not only for demonstration purposes, but also for the investigation of definite problems, have been added. A short while ago we inspected the plant, and were able to see the many minor modifications which had been necessitated. Gas making and carbonization trials have been carried out, and the performance of the condensing, scrubbing, purifying apparatus, &c., examined. The installation, it should be emphasized, is not a small-scale model of a gas-works, but contains many features which differ from usual practice. This fact has made it necessary to conduct preliminary trials before proceeding with a definite research programme. As a result of the tests and alterations, the suitability of the horizontal setting and auxiliary plant as a carbonizing unit has been established. Dr. Parker states that tests on the vertical retort setting are now practically complete, and that it is hoped to embark on a research programme almost immediately.

As an appendix to the Fourteenth Report a brief description of a method of preparing coke sections is given. It is pointed out that the examination of a lump of coke with the object of determining its texture is normally a difficult matter. The method described, which is due to Dr. Rose, of the Koppers Company, consists in filling-in the pores and cracks of a plane section with a suitable white cement, and polishing the surface so obtained. The cell walls of the coke are rendered easily visible against a strongly contrasting background, and inert materials such as shale are clearly brought out.

After reading the report, the thought remains that there is need for action along definite and practical lines. Among the great problems confronting the industry at the present time is the production of a coke suitable for domestic use. We want to know what is the right texture which will ensure easy ignition and free burning, and how coke having these desirable characteristics can best be manufactured. It occurs to us, for example, that the vertical setting could be used for investigations having this object in view. Research workers should not become so absorbed in their work that they fail to realize the ever-changing needs of the industry. What is of first-rate importance at a certain period may after a few years become of secondary value, due to entirely changed conditions; and it is a grave mistake to devote time to a subject which has but little relation to the demands of the day, though it may be of absorbing interest to the workers themselves.

The Tankless Gasholder.

British gas engineers have now had a very thorough introduction to the tankless (piston, dry, or waterless—which adjective is to become standardized?) gasholder. The "JOURNAL" claims an early reference to the invention, in May, 1915. At that time the Augsburg-Nürnberg Company were trying-out small holders of the tankless type, in which the sealing liquid was distributed from a tank carried on the centre of the disc; the tank being supplied from an open fall-pipe depending from the roof and fed from the collecting annulus in the base. The next news was supplied by M. Bonnet's paper to the Société Technique in 1922, which must have been inspired by the commencement of work on the Douai holder. Last year the latter was the main feature of the delightful excursion from Paris; and the less fortunate members of the Institution were able to inspect a scale model of it at the "Electricals" earlier in that memorable week. At Douai M. Arbel gave a lecture at the base of the holder itself, which then became a veritable Tower of Babel as the large party of visitors climbed all over and inside it.

Now M. Rolland d'Estape, President of the Société Technique de l'Industrie du Gaz en France, and Honorary Member of the Institution, has favoured the latter with an interesting paper giving further details of the holder at the Etablissements Arbel at Douai. The capacity of the vessel is 970,000 c.ft., and could be increased by half on existing lines. The height of the structure is 118 ft. to the eaves; the diameter of a circumscribing circle is 111 ft.; and the 88½-ton disc throws a pressure of nearly 4 in. W.G. The main details of construction are well known now; but interesting particulars as to the partitioning of the sealing fluid containers and the practically fool-proof working of the pumps are given for the first time in the paper.

We remarked above that engineers in this country have now received a thorough introduction to the dry gasholder; and when our friends on the Continent are heard extolling its virtues, and the formidable list of advantages of the design is read, it seems strange that no report

comes to hand of a contract for a works in these Isles—for the economy realizable is set at 5 to 20 p.ct. for holders above 350,000 c.ft. capacity. Is it a case of insularity or our inherent conservatism and dislike of new departures? Is it distrust of the lofty and permanent structure required for a dry holder of even medium capacity? As to a large example of the design in America we have at present no definite facts or figures. Let us examine the advantages as enumerated by M. d'Estape.

The necessity for warming the tank and the cups is removed, and with it the cost of installing and maintaining a boiler and pipes for the purpose. This is something to appeal to the gas engineer of the Continent or the States, but is apt to be met with apathy on the part of the great majority of gas men whose responsibility lies in our less rigorous climate. The constancy of the pressure thrown by the disc of a dry holder constitutes a very real advantage, enhanced by the fact that by the simple expedient of placing concrete blocks upon the disc, the pressure can be varied between wide limits—in the case of the Arbel holder from 10 to 300 mm. W.G. We are reminded of the often useless (so far as pressure, but not storage, is concerned) top lift of column or spiral-guided holders, now that, through legislation, more thought has to be given to minimum pressures in consumers' services at the far end of a district. Mr. Norton Humphrys dealt with the subject on p. 254 of this volume of the "JOURNAL." As regards the next point—rigidity under wind pressure—we read that "columns can be neither completely rigid

FOUR OF THE DIPLOMA WINNERS.

Messrs. T. Dyson, T. H. Prater, C. Bateman, and T. V. Blake.

nor absolutely vertical, and the lifts of the telescopic holder are subject to violent wind stresses." That is so; but they have stood the strain extremely well. The skill and knowledge of the designers have allowed the pressure to be taken up and distributed without danger to the structures; and modifications to such essential details as the carriages of spiral holders have ensured the sweetest working even in the fierce storms which assail our coasts. Paint, of course, need only be applied to the exterior of the tankless holder, for the interior surface is continuously dressed with an excellent preservative. Comparative figures in this regard would be welcome. It should be borne in mind that the spiral-guided design has greatly reduced the cost of this service by eliminating the most troublesome part of the job; and the external flanges and the angles of the polygonal structure add many square feet to the surface and many hours of work for the painter. The foundation work is a source of great economy in the construction of the dry holder, which must account for a considerable portion of the stated 5 to 20 p.ct. over-all economy, for we learn that the "necessarily precise plating work called for by the tankless design is costly."

M. d'Estape produces but one disadvantage to weigh against the foregoing—the possible irregularity of the tar pumps, and their running costs. We are not impressed by this, for the weir arrangements in the tar wells give plenty of rope to the engineer who has a repair to do; and a few 1½-H.P. electric motors each running for a summer-time maximum of about three hours in the twenty-four do not insert an alarming figure in a profit and loss account. To the solitary disadvantage quoted, however, we would add one—æsthetic, perhaps. Some advocates of dry holders insist upon their sightliness as compared with their forerunners; but we believe that the great majority of people would rather live near, or see on the skyline, a spiral-guided holder. Its elevation is not altogether unpleasant, at times it almost disappears; painted green, it does not seriously disturb the harmony of a view—witness the Christchurch holders from the London road; withal, there is life about it. Whereas the tankless holder for ever rears its head aloft.

Points from the Discussion.

Keen disappointment was felt that the President of the Société Technique had been unable to leave France and present his paper in person; but a most efficient substitute was M. Baril, of the Société d'Eclairage, Chauffage, et Force Motrice, who admirably rendered the English translation of the paper. We must honestly confess that the discussion was as informative as the paper itself, and went strongly in favour of the tankless design. The President, in opening it, made a strong point of the dryness of the gas from these up-to-date containers. Mr. Leather indulged in mild criticism, and was followed by the heavy artillery of Mr. Milbourne. He revealed the interesting fact that the inspection galleries round these holders serve a secondary purpose in strengthening the structure against wind pressure. In praising the new design, he laid strong emphasis upon the absence of corrosion, which has caused engineers furiously to think since wrought-iron and steel plates deteriorated in quality—or town gas, as some opine. Mr. Milbourne considers that a working example is needed in this country to overcome the conservatism of our engineers; and he realizes that the tankless holder in this country has to compete with the spiral-guided design, which means that its economic cost limit must be considerably higher than abroad. Mr. G. M. Gill imparted the information that in the States, whence he has just returned, orders have been placed for dry gasholders of a total capacity of some 65 million c.ft.; two or three to be of 15 million c.ft. capacity. This news is astonishing. It is extraordinary, too, that spiral-guided holders are practically disregarded on the Continent and in America. Several minor points were then raised and answered in French by M. Baril, who was then heartily thanked for his presence and the trouble he had taken.

New Carbonizing Plant at Stretford.

The purely practical paper is a welcome necessity; and Mr. R. E. Gibson's contribution on the Garston Works last year (for which he has been awarded the H. E. Jones London Medal) had a counterpart this year in the "Selection, Design, and Construction of New Carbonizing Plant at Stretford," by Mr. W. M. Carr. Without touching upon design and construction, the author could have prepared a weighty contribution upon selection of plant alone; but he skilfully compressed a great amount of argument into a comparatively small space, and set out his case with extreme clarity. The problem of selection, he says, has become increasingly difficult during the last few years, owing to the great fluctuation in the relative values of coal and residual products; and his decision was made in favour of the type of plant best suited to meet these variations. That an extension of capacity was essential became obvious when 641 million c.ft. was sent out in 1923, as compared with 485 millions in 1921; the maximum day's sale being 2,609,000 c.ft. in the winter of 1923-24, as against only 2,138,000 c.ft. in the previous winter. Further, in view of the undertaking serving Trafford Park as well as a rapidly growing residential area, 7½ p.ct. annual increase was budgeted for instead of the more usual 5 p.ct.

With full realization of the fact that the cheapest gas is not necessarily dependent upon the highest yield of gaseous therms, Mr. Carr took into consideration his

facilities at Stretford for the purchase of cheap slacks and the low freightage which he enjoys. An extensive coke market and the necessity for high calorific value gas (in order to avoid capital expenditure on mains) were important factors. Further, in changing hands, the undertaking had already suffered an increase of 140 p.ct. in capital charges, and a close watch had to be kept upon expenditure. Such considerations left verticals, chamber ovens, and horizontals in the running. Verticals were ruled-out because of the expediency of carbonizing local slacks; and chamber ovens suffered disadvantages in that the units were deemed rather large for a medium-sized undertaking, that charging and coke handling are somewhat complicated, and that there would be a possibility of gas quality varying awkwardly between charging times. However, chamber ovens had the distinction of being compared with horizontals for working costs on a make of 650 millions per annum—taking the raw coke consumption of the former, with reversible generators and outside producers, at 12 p.ct., as against 15 p.ct. with the latter. It appeared that the extra coke yield would be almost balanced by extra capital charges, and there was the probability that the resulting coke—from carbonizing slack in the ovens—would be unsuitable for domestic purposes. The deciding factor was the urgency of the work—horizontals could be installed in a shorter time.

So horizontals won the day, and it was decided to construct a new house containing nine beds of tens (24 in. by 18 in. by 22 ft. retorts), and then proceed with rebuilding the old house with the substitution for the old plant therein of two benches of eight settings each. Thus the total capacity will be 6 million c.ft. of straight coal gas a day; the retort-houses being served by one set of stoking and coal and coke handling machinery. Before proceeding with the second section of his paper, Mr. Carr commented upon the Wollaston producers which it is intended to instal, and developed an interesting comparison of the economics of retort heating by producer gas and coal gas. The Wollaston producer has been proved to function efficiently even with coke breeze through a ½-in. mesh, owing to the fuel being passed over a series of trays by mechanical scrapers—a process which first allows it to dry, and throughout its progress permits free passage of the blast. As for outside producers in general, their heating efficiency is about 16 p.ct. lower than self-contained ones; but the possibility of employing rough slack or breeze persuaded Mr. Carr that in the Wollaston machine he had a good thing. It must be recognized that outside producers allow a portion of the gas to be used for dilution of rich coal gas.

As regards retort heating by coal gas, this is often economically possible near the coalfields (providing there is ample carbonizing plant to meet the demand for gas) for the net cost of coal approaches vanishing point under certain conditions of the residuals market. Equivalents of gas and coke for retort heating may be taken as 40,000 c.ft. and 1 ton respectively; and the costs at Stretford would work-out approximately to 2s. 6d. and 3s. 5½d. per ton carbonized for gas and coke respectively—allowing 2½ cwt. of coke per ton. These are gross figures; but when credit is taken for the extra coke for sale which would result from gaseous firing, and a debit is made for the theoretical maintenance and capital charges of the extra plant required, the saving realizable by coal gas firing is shown as about 17d. per ton. The author points out that on the basis of the above figures, had surplus carbonizing plant been available during 1924, and the whole plant adapted for coal gas firing, a saving of approximately £4000 could have been effected on a make of 641 million c.ft. Such were the main considerations which led to the adoption of settings with normal self-contained producers and supplementary arrangements for working on producer gas, coal gas, or a mixture from external sources. For the design, Mr. Carr was jointly responsible with Mr. H. J. Toogood, of Messrs. Robert Dempster & Sons, Ltd.

In the section of his paper dealing with design, the author refers to a great many details and advances numerous valuable opinions; and it would be useless to attempt a *résumé* of the matter, which merits close study in connection with the drawings. We would, however, direct attention to the design adopted for the self-contained producers. Mr. Carr favours a producer as nearly square as possible, holding that a higher efficiency is secured therewith than with the long narrow shape. The retorts are of 95 p.ct. silica; and the keystone of the producer arch is extended upwards and incorporated as part of the elliptical combustion chamber (the complete specification relating to the latter design has just been published by the Patent Office and abstracted in our columns). The suggested procedure for changing over from coke to gaseous firing is described; and then the author goes on to discuss at some length the modified Congdon standpipes which he has installed, and the conditions he considers essential for their successful working.

In the third section of the contribution, interesting points from the actual erecting work are mentioned; and it is shown, from observations and figures collected over four months' working, that the installation will live up to expectations. Lancashire and Yorkshire mixed slacks, under 1-in. screen, worked in 12-hour charges, over a six-day experimental run gave 75·96 therms per ton of 529 B.Th.U. gas, with 12 cwt. of coke available for sale. The average inerts totalled 10·7 p.ct. The moisture and ash contents of the coal were 3·3 and 11·0 p.ct. respectively, fixed carbon 55·7 p.ct., and volatile matter 30 p.ct. The heat balance showed a net efficiency of carbonization of 82·04 p.ct. The normal weight of charge with the Fiddes-Aldridge simultaneous stoking machine is 16 cwt. with washed slack, and 17 cwt. with dry slack. Excellent testimony to the standpipe system is found in the fact that it has resulted in a reduction of the H_2S content at purifier inlet from 749 to 594 grs. per 100 c.ft.

A Good Discussion.

As the President remarked, an adequate discussion of Mr. Carr's paper might take a day, full as the contribution was with considered opinions and *raisons d'être*. Both Mr. Bell and Mr. Toogood, who followed the President, referred respectively to the author's father, Mr. Isaac Carr, as "the one who supplied the cheapest gas in the world," and "whose name is brought to mind by the very mention of cheap gas." Mr. Toogood, expert that he is, raised numerous points and stressed the fact that the author had all through kept the variable residuals market uppermost in his mind, and especially the Stretford coke market. This speaker's comments on the construction of the silica settings, the producers (which he designates the driving force of any setting), the screen-bar grates, and the tube regenerators should be studied, for a précis would be superfluous. Mr. Collett of Sheffield was at variance with the author as to coke quenching—he believes in spraying in front of the settings rather than mass quenching in skips; and Mr. W. B. Leech criticized the size of retort for the slack coal used, thinking that at Beckton the coke is better and that more therms are obtained with a smaller section. However, experiments are being carried out by the Gas Light and Coke Company, and definite results would be appreciated. Mr. R. E. Gibson, remarking upon the author's use of slacks, supports a contention which we ourselves have stressed from time to time—that if all adopt some particular method of carbonization with a certain kind of material, the price of the latter will soar, and economy through the process will disappear. The Chief Engineer of the Gas Light and Coke Company added his congratulations to Mr. Carr, especially remarking upon the success obtained with the modified Congdon standpipe. We are glad that the author in his reply took exception to Mr. Samuel Shadbolt's remark "that considerations of the conservation of our coal supplies did not trouble Mr. Carr." Nowadays, this is rather a serious allegation against an engineer; and it is difficult to see on what hypothesis Mr. Shadbolt based his comment.

The discussion had to be closed owing to pressure of time, and the author replied fully to the many points raised. More than one speaker in the discussion regretted that the paper had not been available earlier, so as to allow of fuller consideration and the sifting-out of controversial topics.

The Benevolent Fund.

First thing on Wednesday morning, consideration was given to the affairs of the Benevolent Fund. The income for the year amounted to £534 10s.; and assistance to widows, orphans, and aged members amounted to

£489 18s., and other disbursements left a credit balance for the year of only £5 16s. 11d. The demands upon the fund this year will be much greater. Although there has been a response to the President's appeal for increased funds, and one of the new honorary members of the Institution (the Rt. Hon. the Lord Mayor of Manchester, Mr. Alderman Fred. J. West) has contributed £100 for investment in favour of the fund, the Committee feel that their limited financial resources impose a great restriction upon their relief of genuinely necessitous cases.

Wrought-Iron Tubing Inquiry.

The first technical item on the *agenda* for the same sitting was the report of the Wrought-Iron Tubing Inquiry Committee, whose Hon. Secretary (Mr. R. H. Ruthven) presented it. This is a subject which has very opportunely been taken in hand. It was first raised by a letter addressed to the "JOURNAL" in 1923 by Mr. Albert Stokes, Gas Supply Manager of the South Metropolitan Gas Company. Early in 1924 the Institution forwarded a questionnaire relating to the matter to 309 gas undertakings making 100 million c.ft. and upwards per annum. Opinion is about equally divided as to whether there has been, or has not been, any decrease in the "life" of gas barrel, compared with supplies prior to or during the war. One of the questions was: "Do you specify that such material should be made from wrought-iron and not from mild steel strip?" Of those who replied 60 p.ct. specify that material supplied should be made from wrought-iron and not from mild steel strip. From answers received to a question as to whether the material is submitted to any test to ascertain its quality, it is clear that it is desirable that steps should be taken to formulate a standard test. On the evidence obtained, as set out in the appendices to the report, it is the unanimous view of the Committee that steps should be taken by the gas industry to ensure that gas barrel supplied to the industry is composed only of superior quality wrought iron. To that end it is suggested that a specification and tests should be drawn up; and for that purpose the services of a metallurgist should be commissioned. In Appendix II., reference is made to a simple etching test for the rapid differentiation of steel from wrought iron. The Committee recommend the use of wrought-iron piping; but at the same time they direct attention to the deleterious effects produced upon gas barrel—whether of iron or steel—arising from internal corrosion, due to the presence in the gas of carbonic acid, oxygen, and water vapour. It is suggested that all practicable steps should be taken to reduce to the minimum the amount of oxygen contained in the gas. Valuable accounts are given of work on the subject carried out by the South Metropolitan Gas Company and the Gas Light and Coke Company.

Interesting Comments.

As mentioned above, the report was introduced by Mr. Ruthven. It was stated by him that the Council of the Institution had not had time thoroughly to consider the recommendations of the Committee, and after this has been done, if approved, the Committee will go forward with the matter. The next thing the Committee would wish to do would be to consider and discuss the question of the specification with the manufacturers of tubes, in order to obtain their opinion. Some interesting experiences which Mr. E. F. Keable had at Gorleston during the bombardment in April, 1918, were given by him, and plates from a holder which had been pierced by enemy shells were shown, together with photographs. In our report of the discussion, we have included three of these interesting mementoes. He also supplied information as to the manner in which repairs were effected. In connection with these, the water had to be lowered in the tank, to permit of the work being executed from rafts. This gave him a good chance of examining what was going on inside the holder. He described the condition as nothing short of a shower bath. He was surprised at the amount of evaporation which took place in the holders. The water vapour was constantly rising, and forming beads on the crown, and then falling into the gas. Water troubles on the district have led him to think deeply about this matter, and, in order to reduce the evaporation, he now uses a paraffin surface for the whole of the water inside the holders. This remedied the trouble. The amount of paraffin oil used in a 100-ft. diameter holder is 120 gallons; and this is introduced just before the hot weather comes. Trouble with a 3-in. tube used in the water-feeder to a waste-heat boiler evaporating some 4500 lbs. per hour, was mentioned by Mr. H. D. Madden, of Cardiff. This tube got badly pitted in about three weeks. The curious thing about it is that other boilers have not given any trouble in this way, and Mr. Madden has not been able to discover the cause. It was announced by the President that the Committee have engaged the services of an experienced metallurgist, who has already prepared a draft specification which will receive the careful consideration of the Committee. Though the remarks made did not deal specifically with the report, it was clear that the feeling of the members was that the matter is of considerable importance.

Refractory Materials.

As usual the report of the Refractory Materials Committee is both lengthy and useful. Thanks to the Privy Council for Scientific and Industrial Research, it has been possible to present reports of the work of the British Refractories Research Association which are of special interest to the gas industry.

Of particular importance is a communication by Mr. A. J. Dale on "The Relation between Under-Load Refractoriness, Ordinary Refractoriness, and Composition, Physical and Chemical, of Refractory Materials." It has long been realized that cone refractoriness is a very limited guide to the prediction of the behaviour of a brick in a retort setting, principally because there it is under stress, and therefore fails at a much lower temperature than that required to cause the material to flow under its own weight, as in the old specified laboratory test. In addition, the time for disposal on any test of refractoriness is very limited compared with the required life in practice. Hence it is desirable that the test should yield data which can be extrapolated to eliminate the time factor. In the report Mr. Dale records measurements of the strain exhibited by both clay-grog mixtures made up in the laboratory, and sixteen firebricks representative of manufacturers' products, when heated under load up to, and maintained at, 1350° C. for two hours, and also when heated up to the temperature at which complete collapse occurs. For each material chemical and physical properties, as well as the cone refractoriness, determined by the commonly-accepted methods, are set out. It is in the interpretation of the results, together with a suggested classification of firebricks based on their behaviour under load at high temperatures, that the paper is most welcome. Each brick exhibits a thermal expansion up to some temperature, at which it is neutralized by subsidence. The point is indicated by a levelling-out of the dilatation curve; and the corresponding temperature must be regarded as being the lower limiting value of a critical range which is of fundamental importance in refractory testing. The commencement of pronounced contraction of the test piece marks the upper limit of this temperature range. By following the subsidence of the material throughout the two hours during which it is maintained at 1350° C. in the refractory load test, curves can be plotted, and from their slope it becomes possible to prophesy the extent of subsidence under prolonged heating. Also, the characteristic constants of these curves fall into three classes corresponding to the three types of failure of refractories under stress. Some products show little sign of distortion right up to the temperature of complete failure, when the test pieces shear abruptly with well-defined fracture; others very gradually deform, and at the temperature of complete failure squatt, there being little sign of fracture; while the remainder are intermediate the extremes, and show mild signs of squatt and of fracture. In consideration of refractoriness *per se*, one would recommend the first class of products but for the fact that some additional advantage in the way of reduction of porosity and reduced penetration is gained by slight subsidence of the materials; and it may well be that for refractoriness the products of class three are the

best all-round ones. Study of this and other papers shows that the assessment of the qualities of bricks can only be made by gas engineers through their own research departments, who will find papers like Mr. Dale's invaluable in pointing out the way for systematic classification of refractories according to laboratory tests, which should be coupled with large-scale experience.

Speaking of the selection of high-temperature insulating materials, Messrs. A. T. Green and H. Edwards point out that this cannot be based on insulating efficiency alone. A durable construction at the temperature and under other conditions of working is of first importance. Slag wool, for instance, should not be subjected to temperatures over 700° C. for any length of time, because of its tendency to disintegrate and form a powder, with consequent reduction in the occupied volume. This loss in structure is accompanied by a great reduction in insulating efficiency. Before selecting an insulating material it is advisable to have a complete knowledge of the circumstances of its future use, particularly regarding the face temperature to which it will be subjected. The following data will then serve well in the selection: Comparative cost, insulating efficiency, refractory test, porosity, mechanical strength, and the temperature at which the material begins to lose its structure.

The 1912 Gas Engineers' Specification for refractoriness has led to slightly variable results according to which of the two optional methods was adopted. The Refractories Committee have now remodelled the test under the title "The Gas Engineers' Refractoriness Safety Test," which is described in a paper by Messrs. T. F. E. Rhead and R. E. Jefferson. The temperature at the first sign of fusion on a cone of standard size is to be regarded as an index of refractoriness. The decision to avoid introducing a load test as employed in work detailed elsewhere in the Committee's report is claimed justifiable by the simplicity of the suggested test and the fact that any load test as now employed does not sufficiently conform with practical conditions as to be regarded as final. Attention is drawn to the necessary care in the measurement of the test piece, and useful hints for obtaining increased accuracy in this direction are given.

Other matters of considerable interest are dealt with in papers by Messrs. T. F. E. Rhead and R. E. Jefferson on "A Few Experiences with Refractories in Vertical Retorts;" and by Mr. A. J. Dale on "An Investigation of the Effects of Load, Temperature, and Time in the Deformation of Firebrick Material at High Temperature," and "Some Fallacies to be Avoided in the Standardization of any Method of Testing the Load-Bearing Capacities of Refractories at High Temperatures; and a Suggested Method for Standardization."

Need for Co-Ordination of Information.

In the course of the discussion on the report, Sir Arthur Duckham was responsible for a suggestion which was entirely endorsed by other speakers. It was to the effect that a great deal of assistance could be given by having a central committee to deal with information. In his own firm, for example, something like £3000 a year is spent in firebrick research alone; and all the information gained is absolutely at the disposal of the gas industry. This is the true spirit of research; and a general recognition of this by manufacturers in other fields would heighten the rate of progress. Sir Arthur draws attention to the excellent work being done by Mr. Rhead at Birmingham, and by the Gas Light and Coke Company. If, he suggests, we had some system of co-ordinating this work, we should make considerable headway. There is no question that refractories play a vital part in the process of gas manufacture. If, for example, we can get a plant which would have a working life of (say) fifteen years, think how this would reduce the cost of carbonization. Mr. Rhead is of opinion that, if gas engineers only realized the variations in materials, even from good firms, they would go in for testing a good deal more than they do at present. He has found that some refractory material manufacturers have erratic mixtures because they measure by the barrow load, and not by proportioning machinery. There would seem to be two extremes in this country. Some firms have reached a high degree of technical efficiency; others trust to luck that the material will come out all right—which it frequently does not! Mr. Williams, of Altrincham, asked whether a simple test, suitable for a small works, could be devised which would give an approximate indication of the quality of the material; but Mr. Leather said it was impossible, with such complex substances as refractories, to have such a test. Mr. Leech, referring to the generosity of Sir Arthur Duckham, said that, if the Institution took the matter up, they would doubtless find that manufacturers both in this country and abroad would be willing to give them the benefit of the information which they had gained. On a recent visit to the Continent, manufacturing firms had placed any amount of information at his disposal. Mr. Gill thinks that many engineers seem to forget the existence of the Institution of Gas Engineers Specification for Refractories, and emphasizes that more use should be made of it. He is of opinion that an under-load test would prove of great value. The President observed that full support should be given to the work of the Refractory Materials Committee. It mattered not how well a setting was designed, or how well it was constructed, unless the material would stand the heat and superincumbent pressure in ordinary practice it would be of no use. Mr. Leather, in the course of his reply, stressed the point that it was not sufficient that goods be ordered to a specification; it must be seen that they really were to specification.

Illumination.

The report of the Sixth Session of the International Commission on Illumination was presented by Mr. Watson, of Doncaster, and Mr. Dunn, the Secretary of the Institution of Gas Engineers. The representatives at the Conference, which, as readers of the "Journal" will remember, was held in Geneva last year, numbered about 40, covering gas, electricity, and physical interests; and they came not only from our own country, but from France, Italy, Switzerland, the United States, Poland, and as far away as Japan. The papers submitted at the conference, abstracts of which appear in the report, were connected with photometric dimensions and symbols, heterochromatic photometry, factory and school lighting, and automobile lighting. One or two new features were introduced, and there was a natural transition from what may be termed the scientific or theoretical consideration of illumination to the practical application of lighting generally. Decisions were reached at the 1921 conference as to certain photometric quantities, such as luminous flux and intensity. At the meeting last year further progress was made; and definitions covering brightness, reflection, absorption, transmission, and the like were formulated, and these are included in the report. The submission of three papers on practical engineering, and methods of publicity among all classes of consumer, which referred to the various illuminants that are available to the public, was something new. Mr. Watson suggests that our own country is not behind the United States in matters of this description, and that the larger undertakings, and many of the smaller ones, are acting much on the same lines as suggested in the papers. Work at present in hand consists in the classification of streets and thoroughfares in order of illumination requirements, in the study of the means for higher illumination standards for streets, in view of the increased amount of fast-moving traffic, and the desire of increasing the height of the light source, in order to get a greater distribution of light on the ground, and to avoid the possibility of glare.

During the discussion on the report, Mr. Davies, of Chesterfield, suggested that the problem of reflection should be investigated with a view to improving street lighting. He mentioned that the electricity industry was experimenting on these lines. In regard to this, Mr. Watson said that the Sub-Committee on Street Lighting had this point in mind. Those members of the Institution of Gas Engineers who had the good fortune to visit the Physical Laboratories of the South Metropolitan Gas Company on Thursday last were able to see work of this nature in progress, the outcome of which will be awaited with interest. Mr. Ferguson Bell stressed the point that it is not by any means the intention of the Institution to lose interest in the use of gas for illumination purposes.

Effect of Ash in Coke Production.

The Gas Research Fellowship Report describes what effect the addition of 5 p.ct. of each of a number of common inorganic compounds to an almost ashless Yorkshire coal prior to its carbonization at 500° and 800° C. has upon the chemical and physical properties of the cokes produced. When carbonizing at 800° C., iron oxide, and, to a smaller extent, lime and calcium carbonate, reduce the amount of nitrogen left in the coke, while alkali has the reverse effect. The sulphur contents of cokes produced with the addition of iron oxide, lime, caustic soda, and sodium carbonate were higher than that of the "pure" coke; the greater difference being with the iron oxide and calcium oxide. Though the "iron oxide" coke had as high a total sulphur content as the "calcium oxide" coke, its sulphide sulphur content was much less. This is explained by the oxidation, during the cooling of the coke, of the ferrous sulphide to free sulphur and free iron, which latter constituent was detected qualitatively in the coke. The addition of sodium carbonate was most effective in producing a hard and compact coke of more than double the crushing strength of the unadulterated material. Iron oxide yielded similar results in a less marked degree, but the presence of caustic soda completely destroyed the coking power of the coal.

Judging from the higher volatile contents of the low-temperature cokes containing added oxides, the expulsion of volatile matter from the coal had been retarded by the presence of inert material, most noticeably with iron oxide. This is most interesting, and calls for further investigation. Alumina and silica in the proportions used appear to be without material effect on either the physical or chemical properties of the cokes yielded.

We do not think the report calls for much further comment, for it is not very fruitful as an "idea-giving" medium. It seems to us a great pity that further investigation was not carried-out on the potentialities of last year's Fellowship Report, which bristled with practical possibilities. It may be remembered that Mr. Madden, of Cardiff, asked what size of coke was most suitable for a water gas generator. This is a question which still remains unanswered; and it is just such questions as these which require investigation. A general haze of data and statistics is all very well; but research work, like all other forms of activity —be they scientific, literary, or commercial—needs to be channelled, and the concrete wall of complexity is most easily broken by repeated attack at a point which calls for immediate attention. In view of the difficulties which the gas industry is having to face, the subject of this year's Fellowship Report, though highly interesting, is, to the outside observer, not of first-rate importance.

Dr. Lessing, however, whose work on the catalytic effect of individual inorganic compounds on the carbonization of coal is well known to readers of the "Journal," and who was the only speaker in the discussion on the report, certainly does not hold this view. He referred to the influence of the ash on the carbonizing process as being enormous, and held out the hope that realization of this would lead others to pursue this line of investigation. As to the report itself, he referred to it as an exceedingly important piece of work, and said that in general the results put forward confirmed his own working. Dr. Lessing is of opinion that all work on carbonization will have to be reconsidered in the light of the influence of the inorganic constituents of coal on the yields of volatile therms in the form of gas and tar. After voicing a warning to the effect that the values for crushing strength of cokes determined on small specimens should be treated with great caution, he called attention to the method of carbonizing coal in the form of fine particles which has been adopted by H. E. Newall and F. S. Sinnatt, who, as was mentioned in the "Journal" for Jan. 7, state that heating first produces an ordinary large bubble structure, followed by the production of hollow spheres, known as "cenospheres." Dr. Lessing thinks that this method of attack may yield fruitful results.

Gas Testing in Small Country Places.

Prof. C. V. Boys has the priceless gift of holding the attention of a large audience. Those who had the good fortune to be present at the meeting of the Institution in 1922 will understand what is meant by this short sentence, and will remember the delightful account which he gave of his recording calorimeter. At that meeting all were impressed with the amazing fertility of Prof. Boys' mind; and the paper on "Developments in Gas Calorimetry" which was read at this year's meeting of the Institution is another reflection of his wealth of ideas. He mentions that, in carrying-out their duties, the Gas Referees have been oppressed by the cost and elaborate procedure which have grown up round the ordinary water-flow calorimeters, and which make their provision a serious burden in small country places. This applies less to the equipment within the testing place than to the time required of the gas examiner and the tedious nature of the operation which he has to conduct. With a view to reducing this burden, Prof. Boys has designed a simple equipment which he describes in detail in his paper. As one would expect, it is a highly ingenious and carefully thought out piece of apparatus. In small undertakings, when financial considerations unduly limit the number of tests, it is difficult to find a value for the average calorific value of the gas supplied; and if the number of tests is too small, there is a risk that the gas may, on the few occasions of test, be caught at an unhappy moment when it is in a state of depression. As Prof. Boys points out, tests at such times may not be balanced by others more favourable, with the result that the average calorific value reported may be less than that actually supplied. It is not possible to remedy this state of affairs, because the cost of the tests becomes an item in the local rates. As it is, it is only too often found that the limited number is considered excessive by the local authority. The consequence of all this is that small gasworks have to provide gas which on the whole is of better value than that actually declared, if they wish to be safe from adverse report. It is to reduce this hardship that Prof. Boys has brought forward his simplified testing appliances. This, however, is not all. He indicates a further possibility of obtaining a fair average value by a method of sampling, and suggests that in small country places the gas should be slowly and continuously drawn into a small holder in the testing place, and that the gas examiner should make a test on the gas which should be an approximate average of all that has been delivered since his last test. This suggestion will doubtless be well received by the gas industry. The final portion of Prof. Boys' paper is a description of a special gasholder for this purpose. If this system should work out well, the more important object of the Gas Regulation Act would be attained—and this for the smallest place and at the minimum cost.

Comments on the Paper.

As was to be expected, there were many appreciative remarks on the skill and ingenuity which Prof. Boys had exercised in bringing his ideas to a practical issue. Mr. Whipple, of the Cambridge Scientific Instrument Company, who remarked that the invention was characterized by simplicity, was impressed by the manner in which Prof. Boys had circumvented insulation difficulties. To his query whether Prof. Boys had tried diatomaceous earth as an insulating medium, he received the reply that this substance, though, of course, well known to the inventor, had not been used. The insulating material employed, cork, is entirely safeguarded from the effects of moisture. Prof. Cobb added his unqualified appreciation of the work done by Prof. Boys, at whose hands, he said, complex questions received simple solution. Dr. Colman, Dr. Parker, and Mr. Wood all referred to the question of deterioration of the gas on standing for a lengthy period over water. Dr. Parker wondered whether this difficulty could be overcome, at reasonable expense, by the use of a mercury seal, and made a most interesting observation to the effect that the gas might diffuse through the water lute, and eventually find its way to the atmosphere. Regarding this, Prof. Boys thought the rate of diffusion would be very low, and mentioned that after gas had been stored in the sampling holder for a fortnight no change had taken place. Mr. Wood, on the same question, suggested that, as a result of polymerization of certain of the compounds in the gas, it was conceivable that a solvent would settle on the water. Dr.

Colman drew attention to experiments which he had conducted, and said that in a holder similar to that of Prof. Boys he had never been able to find a definite loss greater than about 1 p.ct. His tests, however, were insufficient to constitute proof; and he suggested that the problem should be thoroughly investigated. Mr. Wood asked what provision was made for preventing the holder from being filled too quickly, and how the contents could be "backed-out" if the supply failed. Prof. Boys, in reply to this, said that the rate of filling was entirely governed by the clockwork mechanism, and, by a clutch device, "backing-out" was allowed for. Part of the discussion centred on the method of arriving at an average sample of the gas made or sold, and whether synchronization of an accurate nature was possible—Prof. Boys intimating that practical consideration should dominate, and that absolute perfection could not be gained, even by incorporating "Heath-Robinsonian" notions; Dr. Smith received confirmation of his suggestion that the apparatus would be suitable for both large and small works. The discussion was greatly enjoyed by a crowded meeting.

This concluded the afternoon sitting on Wednesday. The following morning two highly important papers and discussions occupied the greater part of the sitting.

Town Gas for Motive Power.

A contribution from Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., Past-President and Honorary Member of the Institution, is always particularly welcome; and the short paper on the above subject which he presented was fully optimistic and most encouraging. Town gas for engines has deservedly been more in the limelight during the past year; but few realize that the proportion of that commodity used for motive power in Great Britain and Ireland amounts at present to about 10 p.ct. of the total make, and produces one-half the brake horse-power of all the internal combustion engines in our factories. Sir Dugald looks forward to a continued increase as external, and so internal, trade recovers from the cataclysm of the war. But all must do something towards this recovery, as we heard from the lips of Sir Philip Cunliffe Lister and Mr. Milne Watson last week; and every effort should be made to reduce the price of town gas for power purposes—4d. to 6d. per therm is too high to compete with other sources of power above 100 B.H.P. From 5 to 100 B.H.P., however, one great point in favour of the town-gas engine is that the efficiency remains practically constant under varying loads. The comparative cost figures, given in the paper, for various sources of power, including interest and depreciation, water, oil, and labour, are: Town gas, 0·75d. per B.H.P.-hour; anthracite (suction gas), 0·52d.; coke (producer gas), 0·49d.; and Diesel oil, 0·47d. For electricity, allowing 90 p.ct. motor efficiency, Sir Dugald prescribes a price up to 1·125d. per unit in order to compete for power.

Towards the end of the paper, the gas industry is strongly urged to push forward in this field. Gas undertakings must bring pressure to bear equal to that of their competitors; and the opinion is voiced that even the very small power trade might be held if the engines were let on hire. The gas industry has an excellent example in this direction from the President and the Derby Gas Light and Coke Company. Sir Dugald saw in the Gas Regulation Act the chance of varying methods of manufacture so as to supply a gas equally suited for lighting, heating, and power purposes; and with the same broad view he calls upon gas engineers to study the whole subject of fuels—not only town gas—for he looks forward to the discovery of further useful carbonaceous material in the wilder countries of the earth.

Further Encouragement.

It was doubly appropriate that the President should open the discussion on the above-mentioned paper, for the Derby Gas Light and Coke Company are really showing the way to the development of the power load. Mr. Bell stressed the advisability of regularly inspecting and indicating engines on the district. It is well known that he advocates free fixing and hire-purchase and simple hire terms. While not in favour of pushing differential prices to extremes, he considers that power tariffs should be cut as far as possible; and he would like to see the larger undertakings co-operating with the smaller ones in providing an expert inspector and adviser. At Derby it pays well to have such a man canvassing the district.

Mr. George Helps confessed that he had lost business to oil because he could not sell the gas therm for 3d.; and Mr. P. D. Walmsley introduced the subject of generating electricity by gas so as to counter the business our competitors do with the "individual drive." Mr. Samuel Shadbolt complained of such practice by the electricians as charging, through a special arrangement of bulk supply, from 0·75d. to 0·9d. per unit for power and 6d. a unit flat rate to shopkeepers for lighting on the same district. This is certainly drawing a very long bow (which might break one day); but Dr. E. W. Smith looks a hard fact in the face, and suggests an inquiry by the gas industry to determine the practical means of differentiating gas charges.

Mr. Tookey contributed several useful points. It was good to hear that many who introduced suction-gas plants when the latter came into vogue were now abandoning them in favour of town gas; also to learn of a manufacturer who finds it cheaper to run three small gas engines—theoretically inefficiently—than to take current from the public mains. Further, to have one's own gas-driven generating plant is a safeguard against strikes outside; but a client should be given a proper maintenance service.

We commend to all the verbatim report of the discussion; it will repay careful consideration, and there is much of encouragement therein.

Economics of Gas Production.

The paper by Mr. George Evetts is characterized by common-sense—a quality which is, perhaps, of all qualities the most difficult to attain, and which is the outcome of hard thinking and a broad outlook. The keynote of the paper, the subject matter of which constitutes a striking refutation to the claims of those who, without considering ultimate effects, point unhesitatingly to this or that means of salvation in the gas industry, is "it all depends." Mr. Evetts points out that calculations based on the volume of gas or the tonnage of coal are only useful in so far as they deal with the plant or machinery handling such volume or tonnage, and to this extent affect the working costs. Finally all results and costs must be reduced to the therm. How often do we hear of Chairmen of Committees congratulating themselves that they have made more cubic feet of gas per ton of coal carbonized than they did in a previous year—a statement which, without qualification, signifies nothing. Many discussions have taken place on the variation in the volumetric sale due to changes in calorific value, and statements have been made to the effect that consumers have used the same volume of low-grade gas, compared with corresponding periods when a higher grade was supplied. Mr. Evetts is of opinion that these statements would not bear investigation, and that volumetric consumption increases as the calorific value decreases. He quotes an example. The calorific value was 540 in 1913, and 375 in 1921. The sale in the meantime had increased by 50 p.ct. In other words, 540 therms in 1913 had risen to 565 in 1921, and the thermal sale per consumer was practically unaltered.

The basis of all calculations is the demand for thermal units; but the gas-maker cannot dissociate volume from his considerations. Exhausters, washers, purifiers, holders, &c., are limited in regard to volume. For this reason, though a low-grade gas may be cheaper to produce in the retort house, it may be dearer to sell. Taking gasholders as a case for comparison, assume that the maximum daily demand is 10,000 therms (1·82 million c.ft. of 550 gas). Gasholder storage of 1,600,000 c.ft. would represent 88 p.ct. of the maximum day. If the quality were lowered to 400 B.Th.U., the thermal storage would be reduced to 64 p.ct. of the maximum. To reach 88 p.ct., as before, additional storage of 600,000 c.ft. would be necessary—costing about £15,000. This would add 1·4d. per therm to the capital cost per therm sold per annum (based on 250 maximum days per annum).

Then there is the capacity of the distribution system to consider. Advocates of low-grade gas argue that distribution difficulties can be solved by increasing the pressure at the works; but, as Mr. Evetts emphasizes, the

fact remains that with a higher quality the increased pressure would deal with still more gas, so that a main of given size has a reserve of potential power if the calorific value is increased. Already in many cases gas undertakings have a stiff task in supplying consumers' needs; and this point should be borne in mind. It is shown in the paper that, taking an 18-in. main, 3600 yards long, 166 therms per hour are delivered with a 2-in. pressure drop when a gas of 290 B.Th.U. is supplied, whereas, with a gas of 564 B.Th.U., 390 therms per hour is the delivery figure. Dealing with distribution, Mr. Evetts points to the advantage of erecting outlying holders.

Throughout the paper the author does not merely state opinions; he gives the why and wherefore of them, backing-up his arguments by statistics. He lays stress on the need for taking local conditions into account when adopting any policy, and shows how it may be better in certain circumstances to make 10,000 c.ft. of gas per ton rather than 12,000 c.ft. He demonstrates that the maximum production of gaseous therms per ton of coal is not always the cheapest method of manufacture. With regard to the maintenance, repairs, and renewals of purifying plant, gasholders, &c., it is clear that a low-grade gas would necessitate a larger piece of plant in each case; and consequently fuel, oil, paint, and general attention would be more than in the case of a higher grade, and the costs of repairs and renewals would be greater. These points may appear obvious; but it is only too true that they are often taken into consideration after the event, rather than before. Speaking of leakage, Mr. Evetts says that it is probably unaffected by the grade of gas supplied. Low grade requires higher pressures, but a certain sized orifice would deliver no more thermal units in a definite time, for the increased volume lost would contain less heat units per cubic foot. The paper is full of useful and well-balanced observations; and it is hoped that these few notes will serve to indicate its general trend and its practical value.

THE NEW PRESIDENT.
Mr. C. F. Botley, of Hastings.

Low-Grade Gas.

In the course of the discussion which followed the reading of the paper, several interesting remarks were made by advocates of low-grade gas. Mr. Robinson quite rightly drew attention to the tendency to adjust calorific value in accordance with market conditions. When coke is good, it pays to distribute high-grade gas. At times when residuals fetch poor prices, the leaning is towards gas of a lower calorific value. But what about the consumer? Are these fluctuations either desirable or necessary? Mr. Robinson thinks the policy should be to reduce the amount of coal carbonized and coke produced, and thus attain greater stability. Mr. Shadbolt, of South Bank, on the question whether a cubic foot of 500 B.Th.U. gas performs the same duty as (say) 2 c.ft. of 250 gas, said that, though this might, and did, apply to power consumption, it was by no means so reliable where the domestic load was concerned. Mr. Shadbolt also referred to leakage. He considers that when Mr. Evetts states that a certain sized orifice will deliver no more thermal units in a certain time, as the increased volume lost due to higher pressures would contain less heat units per cubic foot, he assumes something which does not materialize in actual fact. Mr. Shadbolt has found in his area that an increase in pressure has been of assistance in keeping-down the figure for unaccounted-for gas—a remarkable experience. At South Bank, taking the calorific value now (400 B.Th.U.) and before the war (500 B.Th.U.), while the volumetric loss remains the same, the thermal loss has been reduced 27 p.ct. Mr. Marshall had a good deal to say about his low-temperature process, and suggested that low-temperature carbonization should be linked-up with gas-works practice, if success was to be assured. On this point Dr. Smith made the pithy observation that, if such a process is unattractive outside the gas industry, the industry will require a lot of convincing that its adoption would be worth while.

Official Advancement.

Then we heard the report of the Scrutineers upon the election of office-bearers, and new members of the Council. The expected happened. The members had the great pleasure of welcoming Mr. C. F. Botley as the successor of Mr. Ferguson Bell in the Presidential Chair; and an eloquent acknowledgment was made by our friend from Hastings. Mr. J. Wilkinson has been advanced from the Junior to the Senior Vice-Presidency. It is a happy procedure which allows a gradual stepping-up to the duties and responsibilities of the supreme office in the Institution, as it enables one to get thoroughly well-grounded in them. For the Junior Vice-Presidency, Wales has supplied a worthy successor to our Nottingham friend—Mr. H. D. Madden, the Engineer and General Manager of the Cardiff Gas Company. That long-experienced active worker in our organizations, Mr. W. E. Price, with that never-failing geniality of his, once more accepted the office of Hon. Secretary.

Thanks All Round.

Then the sittings concluded by richly expressed thanks to the President and Mrs. Bell—to the former for his work during the year and through the meeting, and to both for the magnificent hospitality and pleasure which they have given to the members. The Chairman and Directors of the Derby Gas Company were thanked for the great favours to come on the Friday. There was an "omnibus" resolution which thanked everybody who deserved such recognition; and then there was a special vote to that paragon of a Secretary, Mr. Walter T. Dunn, who, as we announced in last week's issue, starting as he did as a young man on the work, has now seen through thirty annual meetings for the Institution. And in his duties, those who are best qualified to judge certify that time increases his value. The President and the Council of the Institution of Civil Engineers were very cordially thanked for their generosity in placing so much of their fine building at disposal for this meeting, the proceedings at which had been of such varied interest and of such excellent quality.

In the afternoon of Thursday visits were paid to the Fulham Gas-Works of the Gas Light and Coke Company, the Laboratories of the South Metropolitan Gas Company, and the National Physical Laboratory; and on Friday to Derby. These are items in the programme which are dealt with in special descriptive accounts elsewhere.

GENERAL REPORT.

The Annual General Meeting of the Institution was held on Tuesday, Wednesday, and Thursday of last week, June 9 to 11, in the Great Hall of the Institution of Civil Engineers, Great George Street, Westminster, S.W., under the Presidency of Mr. J. Ferguson Bell, M.Inst.C.E., Chief Engineer and General Manager to the Derby Gas Light and Coke Company. He was supported on the platform by many gentlemen who are known personally or by name to everyone connected with the gas industry.

Welcome to Distinguished Visitors.

The President (who was loudly applauded on rising) said: Ladies and gentlemen, I am delighted to see so many present at our opening meeting this morning, and regard it as auguring a good and successful gathering. Before we commence the ordinary proceedings, I am sure you would like me, on your behalf, to offer a very cordial welcome to the many distinguished visitors who have been good enough to accompany me on to the platform. Not only have we visitors from New York, Australia, New Zealand, the Continent, and other parts, but we have also honouring us with their presence gentlemen here who are eminent in various spheres at home. I can assure them that we very heartily appreciate the signal honour they have done us in coming to this meeting. The industry which the Institution represents is one of the largest and the most important of our public utility services; and we are glad to find these gentlemen agree with us that it deserves encouragement. The capital invested in the gas industry and allied trades is something over £200,000,000 sterling; and it gives practically permanent employment to somewhere about 125,000 men. In these days of unemployment the latter is, I think, a most important factor. ["Hear, hear."] We are specially honoured this morning by the presence of my friend Mr. W. Woolley, the Chairman of the Derby Gas Light and Coke Company. Mr. Woolley is well known in Derby, and takes a great interest in all that concerns the Company over which he presides. I should like to take this opportunity of thanking him for all his assistance and the very valuable advice he has given me during the last twelve months. I was also expecting to see on the platform both the Members of Parliament for Derby; but the Right Hon. J. H. Thomas has evidently been delayed. We are glad to have with us the Lord Mayor of Manchester and the Mayor of Halifax. It is a real pleasure to me on your behalf to offer all these gentlemen a very hearty welcome. I will not occupy your time by going over all the names. Before we get on with the business, I will ask Mr. Woolley to say just one or two words.

Mr. William Woolley: I am very pleased indeed to come here this morning, because I feel that, in electing Mr. Bell your President, you have not only conferred upon him an honour which he so well deserves, but you have honoured the Company he serves, and has served so well for many years. I feel sure under his Presidency you will have a most successful meeting. I trust when your labours are over under his guidance, I shall have the pleasure of seeing nearly all of you at Derby on Friday.

Mond Scheme of Maintenance with Work.

The President: I will now ask Sir Alfred Mond, whom we are delighted to have with us, to address you. Sir Alfred Mond is known, not only as a prominent politician, but as a scientist and a successful industrial magnate—with a lot more of whom the country could very well do. In putting forward his attractive proposals for subsidizing employment, he has performed a great public service. The obvious advantages of maintenance with work over maintenance without work are now recognized by all parties; and we shall therefore be interested to hear what he may have to say on the subject.

Sir Alfred Mond, M.P.: I feel very honoured that I have been asked to address a few words this morning to such a very important gathering; and I will, in the first instance, say how relieved I am to hear your President state that we want a few more successful industrialists in this country. When I think of all the criticism we get to-day for success [Laughter], and of the abuse we suffer from if we show any profits at all, I sometimes wonder whether I do not belong to the criminal classes of this country. [Renewed laughter.] I once said that the only meritorious method of carrying on a modern business seems to be either in liquidation or in the Bankruptcy Court. At any rate, as soon as somebody makes any kind of success, he is denounced either as an exploiter or a profiteer; and that is a very discouraging atmosphere, I frankly must say, to all of us who are engaged in the very difficult and anxious task of endeavouring to maintain British industry under present conditions. I do not think the outside world at all realizes the anxiety and the work that is involved in conducting modern industrial enterprises. You have not merely to watch one country, or home competition, but you have to watch to-day the inventions of the entire world. Competition is now arising in quarters as remote as the Far East; and new ideas which you have to examine are being put into operation by able technicians of all countries. The task to-day is a thousand times more difficult than it was even fifty years ago; and there is another point that is not adequately realized—that no civilized country to-day has got any monopoly of technical efficiency, capital, or trained labour. Therefore, the task has become infinitely more difficult, and we who have been used to considering that the world existed in order to buy our exports, and to buy what we chose to send, now find ourselves faced with a world situation in which it becomes more and more difficult to induce people to buy our goods; while the war has produced national industries in countries often very little fitted to carry them out. At the same time these industries, once they have come into existence, will not be allowed to drop out. Therefore, you have this additional difficulty of restriction, I might say, of our export endeavour. We have succeeded in maintaining a magnificent currency and credit, combined with bad trade and unemployment unequalled in any country in Europe; but I do not think it is always recognized that the interests of high finance and the interests of business are not necessarily identical. Some people look at this country as a country which exists for the purpose of granting foreign credits; but I am in the habit of regarding it as one which has got to employ some 14 or 15 million workmen. It is these divergences of standpoints which make us industrialists not always agree with the pundits of high finance as to what is in the best interests of the country.

I have had to devote during the last few years, both officially and unofficially, a good deal of time to this problem of unemployment. Many of you know that in Mr. Lloyd George's Administration I was Chairman of the Cabinet Unemployment Committee for some two years. Most of the measures of alleviation which have been put into practice, such as trade facilities, export credits, grants to local authorities, and a number of other things, are really the fruits of the labour of that Committee, and have been continued ever since; but there is one thing when you come to work at this problem in detail which everybody finds—that the creation of artificial work is both costly and difficult. You can induce local authorities to dig useless ponds and fill them up again; you can have quite good schemes for the reclamation of land, and things of that kind; but there are great difficulties and cost involved in getting your raw materials on to the spot which makes the total cost of such schemes prohibitive. Another point not fully appreciated is the large amount of capital required in any industry to employ one workman. When you come to work out some of these

schemes, the difficulties are really very great. Therefore, my mind has always been turned to the problem: Why cannot we employ an unemployed workmen, not on the making of roads or in the reclamation of the Wash, but in the factory in which he is usually employed, which requires no new organization, and no displacement of the economic method of giving a man the job he needs in the factory he is used to, where the capital has already been expended and is lying idle? Obviously, if you can, you will save money by obtaining greater value in the way of increased production, and at the same time you are rendering a much greater service to the man in question. Why are industries depressed? We are experiencing difficulties in exporting and in selling goods abroad; and to what is that due? It is due to the fact that our prices are too high for the purchasers. There are two reasons for this. Exchange is one. Then, as we all know, the poverty produced by the war in the world is another; and the question is, How can we bridge the gap between what I might call cost of production and purchasing capacity—not demand, because the demand is there all right? That, to my mind, is the fundamental problem; and that gap is not always so wide as people imagine. I have had case after case illustrating this. I had a case in shipbuilding recently, in which the Chairman in this country of a very large American undertaking had some ships to place; and we were in competition with, of all people, the French. The difference between the British and the French tenders was not very big. On one tank steamer of considerable size there was, perhaps, a difference of £30,000.

Now, at the same moment that you hear of an order which you could get for that difference, you see, on the other hand, thousands of unemployed walking about the streets, and being paid from 18s. to 23s. a week for doing nothing at all. You are spending £100,000,000 a year in the country by paying something like a million of people for doing nothing; and really I cannot understand a business nation going on doing that. Since the war, you have spent more than £300,000,000 in cash, for which you have not one penny in assets. It has all been spent on unemployment relief; and therefore it is that I ask why we cannot in some way marry this sum now being paid in unemployment relief with the cost of production. By enabling our cost of production to be reduced, we can obtain more work. That is the problem in a few words; and I have devoted a great deal of time and thought to a method by which this can be done. I do not say that you can work out in advance every possible detail; but I think I have worked out the scheme in sufficient detail to say that it is practicable. It is based on three or four very simple considerations. First, it involves the surrender of the unemployment allowance as a voluntary matter on the part of the workman, because I think it would be fatal, when a man is entitled to an unemployment allowance, to pass any legislation which would take away from any individual person anything to which he is entitled. Secondly, you must get more people employed than is the case at present; and you must make it impossible for any employer to substitute a man who is employed to-day in the ordinary way by what I might call a man subsidized by unemployment relief. I think my scheme is absolutely watertight on that point. Therefore you are not merely substituting employment in one factory for unemployment in another; and it is for that purpose that I have created somewhat elaborate machinery in the form of trade committees, whose functions will be to watch three cardinal points. Any employer who applied for permission to enable him to obtain what I might call a workman with his unemployment allowance would have to prove to the trade committee that the contract he wanted to take was new work, and that he would not be taking away work from another factory. Many people think that is very difficult; but in the kind of industry which I have visualized, like engineering—of which I know a good deal, because I have been Chairman and Director of engineering firms—and shipbuilding and big industries of that kind, and even the gas industry, it is not so difficult. Let me give you a particular instance. I am interested, as I dare say a good many of you know, in a firm which has done a great deal of work in the gas industry, Messrs. Ashmore, Benson, Pease. We have got some contracts for big gasholders in Canada. It would be easy for a firm like this or any similar firm to show that, if a contract in competition with America or Belgium or any other country, could be obtained on certain terms, we could employ so many more men than we are employing to-day. I am always being told that all I am doing is to transfer a contract from works B, which is less efficient, to works A, which is more efficient; but my answer to that is that what I am doing is to get the contract for works C, and that under present conditions works A and B would never get the contract. If, therefore, works C gets this work, you obtain very much more work and more employment. My scheme is designed admittedly to enable us to help works C. It would also apply to any local authority and to any public utility undertaking with limited dividends under an Act of Parliament, like a gas company. Any company like this would be able to take on more men; and as you are taking away nothing from anybody, you are simply extending business. Indeed, I have had letters from engineers of gas companies saying that they would be able to employ more people and extend their undertakings immediately if my scheme were in operation. What does the scheme amount to? It would mean a wage reduction by the amount of the subsidy during the time of the employment, but not a wage reduction to the workman. He would have to be paid at the usual district union rates. He would not be paid a penny less, and he would have to be engaged for a reasonable period. His position would be entirely safeguarded, and instead of the Unemployment Fund paying money to men who are not engaged in any work at all, and giving these men the inadequate and miserable pittance which they receive to-day, and which is often supplemented by the Poor Law Guardians, the men would be earning £3 or £4 a week. Now what would happen if this state of things came about? As soon as you put people back to work, and pay them decent wages, they become consumers; and by doing this they help other industries which are not in the scheme at all, and produce employment in these other industries. The moment you start employment anywhere, you get ancillary employment in hundreds and thousands of directions, and you get a reduction in employment of a very considerable size. I was interested to learn only yesterday that the Swiss Government have anticipated my idea by three years. The Swiss watch industry, which was a big export industry, was almost ruined, because, though the Swiss had a good exchange, they had to sell to countries with a bad exchange. The Government had to do something, and they did not sit down and say there was nothing to be done. They worked out a scheme, not exactly in the same detail as mine, but on the lines of subsidizing the watch industry as regards those countries where the currency was depressed. In one year they reduced the unemployment in the industry by one-half, and at the same time they reduced the general unemployment in the country to a considerable degree. It is very interesting to find that an idea of this kind has been put into practice by a small but intensely hard-headed and practical nation such as the Swiss, and has proved that the results which I have deduced would occur have actually occurred. Personally, I cannot understand the timidity of those responsible for our Government which prevents an effort to start a scheme of this kind. I am perfectly well aware that there will be difficulties, and that there will be complaints. There will always be difficulties, and there will always be complaints; and you will never get everything perfect. That has never been done in the history of the world. But in considering a scheme of this kind, surely, when you have got to a condition almost of stagnation in the unemployment of one million people, when you see the devastating results it is having on the efficiency of the workers in this country, when we know that a great many of our best workers have left, and others will continue to leave, these shores, it is time that timidity and hesitation are put aside, and audacity and enterprise substituted. People who know nothing about works and workmen have curious ideas. They seem to think that you can keep both idle, and, when trade improves, suddenly start up to 100 p.ct. efficiency, as if nothing had

happened. All of us who have to carry on works, however, know that is not true. We all know that, if a works is shut down, an extraordinary deterioration takes place, even with the greatest care. We know that staffs, once dispersed, are extraordinarily difficult to re-create. We know that if the best skilled workmen have gone to America they are not coming back just because we want to give them a job. What I fear is that, if industry does improve, we shall find we are not in the position of having the means of meeting it unless, in the interval of depression, we have enough foresight to keep our men in a state of efficiency. After all, we have an army in peace time to defend our country, and that army is highly trained, in order to operate on those unusual and rare occurrences when war takes place. I wonder what any member of the General Staff would say if I suggested to him that it was not necessary to worry about drill or musketry or manœuvres or anything else in peace time, and that these things could be thought of when the occasion arose. The industrial army, in a sense, must be quite as efficient as the military army, and your reserves must also be kept in a condition of efficiency, so that when you want to mobilize them they can operate. What we are doing also is to deteriorate the efficiency of the men at the other end. I mean that we have hundreds and thousands of men who have been trained for nothing, and year after year are becoming absolutely useless. When these men were wanted to fight for the country, there was nothing in the world we were not prepared to do for them. Anybody who likes to go back to that period will see what we said then. Many of these were young men who went straight into the army, and could not be apprenticed and learn any business; and it is a perfect outrage that they have been allowed to walk the streets year after year since. I say it is a national shame that nothing has been done for them.

Therefore, I want this project of mine looked at not merely from the economic standpoint, although there I think it is sound, and still less from the standpoint of the private individual and private interest and private profits, but from the broad fundamental national outlook of the country. The responsible people in this country have got to ask themselves one simple question—how far can we go on as we are to-day? Can we go on any longer? And if we cannot, is there anybody who can put forward a better than the scheme I have outlined, a more practical scheme, and one more likely to achieve results? That is what I want an answer to. If there is a better scheme, let us have it; if there is not, let us proceed with this one. Of one thing I am certain, and that is—you cannot afford to go on as you are doing now, sitting still waiting on events, and hoping that something is going to happen. That is the most dangerous and disastrous policy which this country can adopt on this question. [Applause.]

The President: By your applause, you indicate how greatly you appreciate the splendid address that Sir Alfred Mond has been good enough to give us on a subject which is probably the most important that this country has now to consider—namely, unemployment. I will ask the Secretary to read out the names of some of our distinguished visitors, so that members may know who are on the platform, because it is impossible for me to ask each one of them to address you.

Names of Distinguished Visitors and Overseas Members.

The Secretary (Mr. Walter T. Dunn, M.I.Mech.E.) read the following list of distinguished visitors and members from overseas:

Sir Alfred Mond, M.P.
Mr. Wm. Woolley, Chairman of the Derby Gas Light and Coke Company.
M. Baril, Société Technique de l'Industrie du Gaz en France.
M. Victor Timmerman, Secretary, Belgian Association of Gas Engineers.
Mr. H. Zollikofer, Secretary, Swiss Association of Gas and Water Engineers.
Mr. John C. Irminger, Bergen, Norway.
Mr. J. G. Tooms, Oslo.
Mr. T. O. Morland, Sydney.
Mr. C. F. Snelgrove, Calcutta.
Mr. Stanley B. Johnson (Colombo).

The President: Mr. Zollikofer will say a word or two on behalf of the foreign delegates.

Mr. H. Zollikofer: I thank you on behalf of the foreign delegates for your kind invitation to this meeting; and I wish to convey to you their best wishes for the full success of the gathering. I consider it a great honour to the Swiss Association of Gas and Water Engineers that they should have been invited to the annual meeting of your Institution; and I regard it as a privilege, as well as a pleasure, to represent them. Our President desires me to convey to you the expression of his great regret that he should have been prevented from attending this meeting. As delegate of the Society, I should like to present to the Institution of Gas Engineers an expression of the sympathy and friendship of the Swiss Gas Engineers. It will be a pleasure to me to inform our members in Switzerland of the kind reception I have had here. I wish the British gas industry every prosperity and success in its future development. I wish also to express my admiration of the great effort you have made at Wembley, in showing what the gas industry can do over the whole world. My congratulations are offered to you on the great success of this effort.

Good Wishes.

The President: The following telegram has been received from the Société Technique de l'Industrie du Gaz en France:—

> Au nom Société Technique de l' Industrie Gaz en France nous envoyons meilleurs vœux pour pleine réussite votre meeting avec assurance sentiments sympathie cordiale que notre délégué Monsieur Baril vous apportera.—Le Président, Rolland D'Estape.
>
> [Translation: The Société Technique sends you best wishes for the complete success of your meeting and assurance of the cordial feeling which our delegate, M. Baril, conveys.]

I now wish to suggest that the Secretary should send a cablegram in the following terms to His Royal Highness the Prince of Wales as an honorary life member of this Institution:—

> The Institution of Gas Engineers, at annual meeting in London, send loyal greetings, and wish you continued success in your tour.—Ferguson Bell, President.

I am quite sure I shall not have to put this to the meeting; it will receive your unanimous approval. [Applause.]

Confirmation of Minutes

The President: I now have to move that the minutes of the last meeting be taken as read and confirmed.

Mr. C. F. Botley (Hastings): I have pleasure in seconding that. ["Agreed."]

New Honorary Members.

The President: The next pleasant duty I have to perform is to nominate several gentlemen as honorary members of the Institution. The first name on the list is that of Mr. Charles Hunt, M.Inst.C.E. I have a letter, received yesterday, from Mr. Hunt, in which he says how much he regrets that he is unable to be with us at this meeting; and I am quite sure we equally regret his absence, and hope that he may be speedily restored to health. I am delighted to have on the platform to-day the Lord Mayor of Manchester, Alderman Fred. J. West; and I nominate him as an honorary member. In addition I propose the Presidents of the American, Belgian, Canadian, French, Italian, Norwegian, Swedish, and Swiss Gas Associations as honorary members of the Institution.

Mr. Botley: I scarcely think it needs any words of mine to commend these gentlemen to you. We appreciate very much the association with us of our foreign colleagues. I have very much pleasure in seconding the proposal.

The President: That is carried unanimously, and I will ask Alderman West to reply on behalf of the honorary members.

Alderman Fred. J. West: I find it difficult to choose suitable words in which to express my appreciation of the

great honour that has been conferred upon me by the Institution. I can well believe that in taking this step you desire to reflect in some way the great esteem and regard you had for my father ["Hear, hear"], who, as many of you know, was a Past-President of the old Gas Institute, and to whom you awarded the Gold Medal in 1918. I am also conscious of the fact that in my election to honorary membership you have been influenced by the importance of the civic position which I occupy at the present time; and I can wholeheartedly say that, at the conclusion of my Lord Mayoralty, nothing will give me greater satisfaction than to reflect upon the notice which has been taken by the gas industry of the civic work which I have been privileged to perform. When I do relinquish my present civic position, it will be as Fred. West that I shall hope to enjoy my honorary membership, and it will be in that capacity that I shall hope to retain the regard and good-fellowship of the members of the Institution and to continue to be of some service to the gas industry—thus marking the great honour you have done me to-day. [Applause.]

Appointment of Scrutineers.

The PRESIDENT: If it is agreeable to the members, I propose that Mr. J. W. Auchterlonie, of Cambridge, and Mr. Robert Watson, of Doncaster, be appointed Scrutineers of the balloting lists. ["Agreed."]

Dr. Carpenter and the Birmingham Medal.

Dr. Charles Carpenter was then invited to step up on to the platform, and was accorded a rousing welcome.

The PRESIDENT: Now a very pleasant duty falls upon me as President, and that is to ask Dr. Charles Carpenter to accept the Birmingham Medal. Your Council unanimously decided that this award should be made to Dr. Carpenter; and it is a source of satisfaction, I am sure, to them, as it is to me, that this decision of the Council has been unanimously agreed to by the Institution. This indicates, I think, a desire on the part of the Institution and of the industry for special recognition to be made of the outstanding services rendered over a long number of years by Dr. Carpenter, who occupies a foremost position in the industry. It affords me considerable pleasure to be the instrument to present the Birmingham Medal to one whose name will add lustre to the list of eminent men to whom the medal has been awarded. The medal was founded in 1881 by the Midland Association of Gas Engineers and Managers, to enable the gas industry to recognize merit and assiduity in connection with the manufacture and application of gas; and I know that I am voicing the opinion of all present when I say that no one has done more to improve the scientific manufacture of gas and its distribution than our good friend Dr. Carpenter, so that the recognition is richly deserved. Though it is 44 years since the Birmingham Medal was instituted, it has only been awarded upon ten occasions, which indicates the jealous care of the Institution in the matter of its bestowal. They are very desirous that it should be awarded to those who not only attain high position, but in other ways merit this distinction for their services to the industry. The first recipient, in 1882, was the late Sir George Livesey, who for many years was the recognized leader of the gas industry, a position which Dr. Carpenter now worthily occupies. As President of the South Metropolitan Gas Company, he has more than maintained the best traditions of that great public utility undertaking. Not only has he done that, but he has always been willing to place at the free disposal of the industry his great abilities and unrivalled technical experience, as well as to render assistance to anyone who may desire it. It is, I am sure, the sincere wish of the gas industry and of this Institution that Dr. Carpenter may be long spared to continue the work in which he is engaged. He is a shining example of what can be accomplished by assiduous industry, fixity of purpose, and capacity to control a large undertaking. I have the greatest pleasure, Dr. Carpenter, in asking you to accept this medal. [Applause.]

Dr. CHARLES CARPENTER: Mr. President and gentlemen, it is very difficult indeed to find words to express the thoughts and emotions with which my heart is charged on this, to me, unique occasion. It has been said that time only approves of those decisions with regard to which time has been consulted; and it is now seventeen years since I relinquished what claim I had (if any) as a justification for the magnificent eulogy which has been pronounced by Mr. Ferguson Bell to-day. It is seventeen years since I relinquished technical control for administration. I have always regarded it as a great sacrifice when I decided upon that change. I will not weary you this morning, because the President has already made one suggestion with reference to brevity, and I should be the last person to desire to transgress it. But by that change, while I have made sacrifices, I have, at any rate, been able to do what otherwise might have been withheld from me. Like your President, I have had before me the goal of the gas industry extended in efficiency and extended in its size. One of the advantages that one has in occupying a position associated with administration rather than the technicalities of gas supply, is that one can look on the various problems involved from a detached point of view; and I have endeavoured during all those years to which I have referred to take, as far as possible, full advantage of that fact. Unfortunately I have in many respects been limited. An all-important one has been the amount of energy I have been able to put into my work, and that seems to be a reducing rather than an increasing quantity.

There is one matter to which I would ask you, as engineers, specially to give your attention; and I was particularly reminded of it when I heard our friend the Lord

THE NEW BIRMINGHAM MEDALLIST.

Previous Recipients: 1882, Sir George Livesey; 1884, Frederick Siemens; 1886, Charles Hunt; 1890, Thomas Newbigging; 1892, Sir W. H. Perkin; 1894, William A. Valon; 1897, Baron von Welsbach; 1905, James W. Helps; 1913, Sir Corbet Woodall; 1918, John West.

Mayor of Manchester refer to the respect and admiration with which the gas industry regarded the work and the career of his great father. The matter I have in mind is the carbonization of coal. In the past, this has been too often looked upon as a process for the handling of raw material and its products. I feel sorely tempted to take up your time this morning by a more extended reference to that than I have now decided upon; and it would perhaps be wrong not to take this chance of saying two or three words with regard to that story. We turn back to those early days when the late Mr. John West was a pioneer in the endeavours to reduce or to eliminate the heavy, arduous work commonly carried out in the retort houses in those days, and we remember how his association with a gas undertaking as its manager and engineer gave him the opportunity of putting these ideas into practice. Now I venture to urge that this moral is a very important one. I see, I think, to-day too great a tendency on the part of the

industry to leave the development of the industry to outside sources, rather than take its problems in hand itself. I quite agree we want all the help possible from outside; but I think it is very important that we should not disregard our own duties as gas engineers in connection with the development of our industry as well. I heard, to my great surprise, the other day of a large undertaking that does not employ its own retort setters or bricklayers. Having regard to the important part played by the construction of the retort house in the economy and working of an undertaking, it does seem an extraordinary thing to me that this very essential part of the work of the concern should be placed in outside hands. I think the industry itself should develop itself, and I take the case of Mr. John West as an example of what has been done in that respect. His hand machines he developed at Maidstone, and then put power to them—I think at first compressed air. Then he built larger machines, operated by means of a steam boiler attached to each. For that he substituted the motive power of a steam or gas engine operating through the medium of a wire rope; and finally he went in for the use of compressed air for conveying energy from the engine room to the retort house.

One other matter on which I should like to say a word has reference to the complaints to-day on the part of the gas industry as to the undue preference which is being given by the Government to the transmission of energy by means of electricity. Well, I think that arises from a misconception on the part of the authorities. We must not blame them, because very few of them have the enormous advantage of the able man who spoke so admirably this morning, of a close association with industry—and with an industry which has a sound and solid foundation of scientific knowledge. Unfortunately men of that type are far too few in connection with our Governments. If that were not so, I cannot believe there would be such a tendency on the part of the authorities to support one form of transmission of energy in preference to aiding the development of a much more important one. ["Hear, hear."] But I do think, gentlemen, that you yourselves are not wholly free from, I was going to say, blame in that respect, because I have sometimes thought that you yourselves have forgotten that electricity is simply a means of transmission of energy, not of producing it, and that it is not the only one. If one requires to convert energy into rapid rotative force—as, for instance, in the De Brouwer charger—one can imagine an electric motor to be a very admirable piece of mechanism to do it; but for discharging a retort, what can be more simple than a hydraulic tube with a ram, into which you turn on, or from which you exhaust, water, as the case may be?

Some time ago I had an application from a firm to be allowed to quote for the large generating station which they felt sure we wanted in a large works like those at East Greenwich. I told them that neither at East Greenwich nor any other works of the Company had we got an electricity generating station at all; and it might have been suggested, as the result of this, that we got our electrical energy from some local authority. If I may take a few more minutes, I should like to tell you a little story, because it does point a moral with regard to this particular point. We have got an undertaking—one of the municipal undertakings I have referred to—which for 25 years has been doing its best to take the bread and butter out of our mouths, and it has been subsidized during most of that time by assistance from the rates. To-day it is in the fortunate position of being able to make both ends meet. But what has contributed to this result? It is the fact that a neighbouring gas undertaking, not content with being able to make its own "juice" by gas engines—as was pointed out many years ago by Mr. Denny Lane, although he was a nationalist—and not content with being able to do it by waste-heat boilers, took electrical energy from the municipal electricity department. Now, gentlemen, in face of these facts, I do think that in the matter of the transmission of power and the generation of power through the medium of the electric generator, some of you might, perhaps, look a little at home. I must not take up any more of your time except to thank you very heartily for the great honour you have done me. I know most of the gentlemen who have received this honour, from my friend Sir George Livesey—whom we all admired—down to the most recent, our friend Mr. Doig Gibb, for whom nothing golden is too good. I rejoice to think that to that number of distinguished gentlemen you have to-day been so good as to add my name.

Mr. George Helps (Nuneaton): I wish publicly to congratulate Dr. Carpenter, from the other end of the industry, on being the recipient of this medal.

[Mr. Helps was continuing to speak, when the President asked him to sit down.]

London Gold Medal.

The President: I will now ask Mr. Gibson to come forward. Mr. Gibson, it affords me the greatest possible pleasure to ask your acceptance of this London Gold Medal for your capable paper on "The Construction of New Coal Gas Works at Garston, Liverpool." Since you read that paper, by your courtesy I have been able to see these works; and I can only say that all that was stated in your paper is more than justified. The Liverpool Gas Company are to be congratulated on having an Engineer who is able to construct so admirable a works. I am sure we all congratulate you; and it is with the greatest possible pleasure that I ask you to accept this Gold Medal.

Mr. R. E. Gibson: I appreciate very much the honour you have conferred upon me in presenting me with the H. E. Jones Gold Medal for my paper last year; and I thank you, Mr. President, for the kind, and too generous, words you have spoken in making the presentation. Naturally it is to me a pleasure and a satisfaction that the paper I read was deemed worthy of this distinction, and I shall regard this Medal as one of my most valued possessions.

The Diplomas.

The President: The Secretary will now read the list of Diplomas in Gas Engineering awarded in 1925 under the Institution's Education Scheme.

The Secretary read the names as follows:

First Class.

Thomas Harold Prater, Southgate.

Second Class.

Charles Bateman, Cardiff.
Thomas Vincent Blake, Cardiff.
Thomas Dyson, Huddersfield.
Duncan Dewar Melvin, Glasgow.
Sydney Smith, Birkenhead.

The Diplomas were then presented by the President.

Lord Moulton Memorial.

The President: It is my pleasure now to propose that a sum of £100 be voted by the Institution as a donation to the Lord Moulton Memorial Fund. It will require few words of mine to commend this to your unanimous acceptation. We know that Lord Moulton, who was President of this Institution, was a great scientist, and did great work during the war. He it was who said it was the gas industry, by the contribution of its valuable products, which so materially helped to win the war. We are therefore glad to be associated with this memorial to him; and without further remarks, I will propose the resolution. Mr. Doig Gibb was associated with Lord Moulton, and perhaps he will second it.

Mr. W. Doig Gibb: I have great pleasure in seconding the proposal. It is up to us to do all the honour we can to the memory of so great a man.

The resolution was heartily agreed to.

The Gas Administrator to the Board of Trade.

The President: We are pleased to have with us now on the platform Mr. H. C. Honey, Director of Gas Administration at the Board of Trade. The work he has done is greatly appreciated by us. We do not always get all we want, but we are satisfied that we get a fair hearing.

The Presidential Address.

The President then delivered his address, which will be found on p. 863.

Dr. CARPENTER : We have had the privilege of listening this morning to two admirable and instructive addresses—each of them dealing with an important national matter; one unemployment and industry, and the other the utilization of our coal resources. As an Institution, we rely year by year upon our Presidents to place before us, and before the public, a vivid and realistic picture of the condition of the industry. That has been done this morning in a manner which compares most favourably with all past attempts in the same direction; and we are very much indebted to our President for the excellent way in which he has outlined what our industry can do for the nation, and emphasized the fact that it provides for the most scientific and the most economic utilization of our coal resources. I have very great pleasure in proposing that the hearty thanks of this meeting of the Institution of Gas Engineers be accorded Mr. Ferguson Bell for the admirable address he has given us this morning.

Mr. HENRY WOODALL : I rise with intense satisfaction to second the proposed vote of thanks to our President for his excellent address; and in doing so I should just like to refer for a moment to one little incident which occurred in 1913. Many of you will remember that in that year Mr. Ferguson Bell, in a very charming and graceful way, retired from the Presidency, which he might have taken, in order that my father, the late Sir Corbet Woodall, might act as President during our Jubilee year. I am sure that many of us very greatly appreciated that action. The next year Dr. Carpenter proposed, and my father seconded, the nomination of Mr. Ferguson Bell to the Presidential Chair; but he, for very good reasons, no doubt, felt unable to take the chair that year. We are only too glad to see that though he could not fill it then, he has been able to do so now. I wish that my father had been here to join again with Dr. Carpenter in appreciation of the services which our President has rendered. Last night I spent with my mother. She remembers with a great deal of pleasure meeting many of you gentlemen; and she said—I do not think it will be out of place, and I hope you will not so regard it—I might tell you that she also remembered Mr. Bell's graceful act, and was very glad to know that he had now become President, and was having such a successful year of office.

Dr. CARPENTER : The resolution is before you, and I will ask you to signify your acceptance of it in the usual cordial fashion.

This having been done,

The PRESIDENT said : I very greatly appreciate the all too flattering remarks that have been made by my friends Dr. Carpenter and Mr. Woodall. It is a great honour to me that the proposer and seconder of this vote of thanks should be gentlemen who are so deservedly respected in the gas industry. With regard to the remarks of the seconder, I am glad to know that Lady Woodall remembers us, and takes a kindly interest in our proceedings. On your behalf I shall ask Mr. Woodall to convey to his mother our thanks for her kind message. I have already spoken for nearly three-quarters of an hour, and will now only express my appreciation and my gratitude for all your kindness, and say again what a pleasure it is to me to be your President. I did not accept the nomination of my good friends Dr. Carpenter and Sir Corbet some twelve years ago, because I had not then the necessary health, and I certainly had not the experience which I have since acquired. Thus I do not think the Institution have lost anything by waiting. It is said that everything comes to him who knows how to wait. I waited; and I thank you now for having elected me President. I hope we shall have a very successful meeting.

Annual Report and Accounts.

[See "JOURNAL" for June 3, p. 662.]

The PRESIDENT : I will now move the adoption of the report of the Council for the year 1924-25, and the statement of accounts for the twelve months ended Dec. 31 last. You have all had the report in your hands for several weeks, and I do not think there is anything in it over which you would desire me to occupy your time.

Mr. J. D. SMITH, J.P. (Belfast) : I have much pleasure in seconding that.

The report and accounts were adopted without discussion.

Report of the Advisory Committee on Education.

The PRESIDENT : I will next ask our good friend Mr. F. W. Goodenough, the Chairman of the Advisory Committee on Education, to submit the report of that Committee. We are very much indebted to the Education Committee, and especially to the Chairman, for the great amount of work put into the scheme.

Mr. F. W. Goodenough then presented the report, which, with his statement, will be found on p. 877.

Thirteenth Report of the Investigation Committee.

Prof. J. W. COBB then introduced the Thirteenth Report of the Gas Investigation Committee on "Aeration in Atmospheric Burners, with Special Reference to Lighting Burners." Before doing so, he remarked : In the first place, I may say that I am quite sure you share the regret which is felt by the Research Committee and myself that this report is not introduced by Prof. Smithells, simply and solely because he has been suffering from severe illness—probably the only cause which could have prevented him being present on an occasion of this kind. However, I had a letter only yesterday morning, in which he assures me that his progress towards health and strength is entirely satisfactory. This I have no doubt everybody present will be pleased to hear.

The PRESIDENT : I have a letter from Prof. Smithells in which he says :

> I am writing to say how very sorry I am that I shall not be present at the forthcoming meetings of the Institution. I have got a long way on the path of recovery from my recent troubles; but I am forbidden for a little while yet to attend meetings.
>
> It is a very great disappointment to me that I cannot attend. The programme is most alluring; and it would have been a great pleasure to me to be present to hear your address, to see honour bestowed so worthily on Dr. Carpenter, and to share in what I am sure will be an exceptionally interesting meeting. I need hardly offer my wishes for its success.

I am sure we are all very sorry he is not able to come, but we are delighted to know that he is well on the path to recovery.

Mr. J. W. WOOD summarized the report, which, with Prof. Cobb's introduction, will be found on p. 879.

Fourteenth Report of the Investigation Committee.

Prof. COBB then presented, and Dr. Parker summarized, the Fourteenth Report of the Gas Investigation Committee, on Corbet Woodall Experimental Gas Plant Carbonization Trials at the Leeds University—see p. 898.

Handsome Donation to the Benevolent Fund.

The PRESIDENT : I have a very pleasant message to give you which has just been handed to me. The Lord Mayor of Manchester says : "I propose to contribute £100 towards the Benevolent Fund, which I suggest should be invested so as to bring in an income of £5 per annum." We very much appreciate this kindly thought on the part of one of the latest of our honorary members.

More Good Wishes.

The PRESIDENT : Before we settle down to the afternoon's business, you will be very glad to know of the receipt of a cablegram from Mr. M'Lusky, of Glasgow, who is in America, sending : "Best wishes for a successful meeting."

The Tankless Gasholder.

The PRESIDENT : The first paper on our programme is entitled "The Tankless Gasholder at the Etablissements Arbel, Douai, France," by M. Rolland d'Estape, President of the Société Technique de l'Industrie du Gaz

en France. Unfortunately, M. d'Estape is unable to be here this afternoon; but M. Baril has undertaken to read it for him. We very much appreciate a paper from France on a subject which must be of great interest and importance to all gas engineers.

The paper, with a report of the discussion, will be found on p. 911.

Numerous questions were put to M. Baril, and to them that gentleman replied in French—Mr. Zollikofer kindly undertaking the duty of interpreter.

Carbonizing Plant at Stretford.

The first day's proceedings closed with a paper by Mr. W. M. Carr on "The Selection, Design, and Construction of New Carbonizing Plant at Stretford." This and the discussion appear on p. 915.

The Benevolent Fund.

Wednesday morning's session opened with the Annual General Meeting of the Benevolent Fund (see p. 876).

Additions to the Roll of Members.

The Secretary announced the following additions to the membership roll; and those of the newly elected who were present were introduced to the meeting:

Members.

Anderson, George Edwin, Works Manager, Howdon Works, Newcastle-on-Tyne.
Ashworth, Richard, Engineer, Manager and Secretary, Tamworth Gas-Works.
Atkinson, Richard Littledale, Assistant Manager, Elswick Gas-Works, Newcastle-on-Tyne.
Barnard, Robert Henry, Manager and Secretary, Gas-Works, Wantage.
Beveridge, James Wilson, Engineer and Manager, Gas-Works, Troon, Ayrshire.
Birchmore, Leonard, Engineer and Manager, Louth Gas-Works.
Birks, Falconer Moffat, O.B.E., Mechanical Engineer, Gas-Works, Beckton.
Breaks, Christopher, Engineer and Manager, Ellesmere Port Gas-Works.
Calderwood, Robert John, Gas and Water Engineer and Manager to Spalding U.D.C.
Dean, Harry Watson, Engineer and Manager, Padiham U.D.C. Gas Department.
Dearden, Walter Armitage, Engineer and Manager, Gas Department, Johnstone, Renfrewshire.
Demain, John, Engineer and Manager, Ripon Gas-Works.
Dixon, James Edward, Works Manager, Elswick Gas-Works, Newcastle-on-Tyne.
Greenough, Peter, Gas and Water Engineer, Hindley.
Perks, George Watson, Chief Chemist, Stockton-on-Tees Gas-Works.
Reid, Norman, Manager of Redheugh Gas-Works, Newcastle-on-Tyne.
Robertshaw, Walter Livesey, Works Manager of the Ayre's Quay Works of the Sunderland Gas Company.
Sahlberg, Hans Ferdinard, Director of the Helsingfors Municipal Gas-Works.
Sato, Kenji, Manager of the Omori Gas-Works of the Tokio Gas Company.
Surtees, Gilbert, Engineer and Manager, Uttoxeter Gas-Works.
Watson, Alfred Thomas, Engineer and Manager, Rushden and Higham Ferrers District Gas-Works.
Whatley, Greville John, Assistant to F. H. Jones, Consulting Gas Engineer, London.

Associate Members.

Alexander, Anthony Parker, Engineering Assistant at South Bank Gas-Works.
Bell, William, Second Assistant to Engineer and Manager, Reading Gas Company.
*Bengough, Francis John, Junior Engineer, Nechells Works, Birmingham Gas Department.
Birch, Ernest, Assistant Distribution Superintendent, Stockton-on-Tees Gas Department.
*Carmichael, Stanley, Works Chemist, Avon Street Gas-Works, Bristol.
Cleator, James Radcliffe, Senior Assistant, South Bank Gas-Works.
*Cowles, Harold Austin, Coal Test Works Shift Chemist, Nechells Works, Birmingham Gas Department.
Cox, Spencer H., Assistant Works Manager, Haywards Heath District Gas Company.
*Dupont, Fernand, Chief Assistant Engineer, Neath Gas Department.
Ely, Robert John, Assistant Manager to the Ridding District Gas Company.
Fall, Frederick Percy, Engineering Assistant and Chief Draughtsman, Sunderland Gas Company.
Hart, Edward Holford, Works Chemist, Romford Gas and Coke Company.
Kimpster, William Corbitt, Technical Assistant, Newcastle and Gateshead Gas Company.
*Mortimer, Thomas Rayner, Assistant Engineer and Manager, Brighouse Gas Department.
Nicholls, Frederick, Chemist, Redheugh Gas-Works, Newcastle-on-Tyne.
*Parrett, Jack, Technical Assistant, Exeter Gas Light and Coke Company.
*Prater, Thomas Harold, Chemist to the Tottenham and District Light, Heat, and Power Company.
*Preston, Joe Bray, Technical Assistant, Spenborough Urban District Council Gas Department.
Rioch, John Hunter, Assistant Engineer, and Manager, Gas Department, Inverness.
Robson, Colin, Technical and Chemist Assistant, Elswick Gas-Works, Newcastle and Gateshead Gas Company.
Sheehan, Patrick Joseph, Assistant Engineer, Cork Gas-Works.
Summerson, Roy, Chief Chemist and Junior Assistant at the Gas-Works, Luton.
Williams, Samuel James Downing, Assistant Engineer, Gas-Works, Stourbridge.
*Winch, Egbert Harold, Second Assistant, Cambridge University and Town Gas Light Company.
Woodfine, Cecil Hadlow, Works Chemist and Technical Assistant, Gas-Works, Wellington, Salop.

Associates.

*Clark, Herbert Patrick, Gas Examiner for East Ham, Barking, and part of Essex.
Fleminger, Sidney, F.C.S., Official Gas Examiner and Consulting Chemist, London.
Townend, Frank Sutcliffe, B.Sc. (Eng.), Assistant to Dr. E. W. Smith, Technical Director of the Woodall-Duckham Companies, London.

The President: The Institution is progressing as far as numbers are concerned.

More Telegrams.

The President: I have received a telegram this morning from the Italian Association of Gas Engineers, sending salutations and best wishes to their English colleagues. I have also received a message from the Mayor of Derby, regretting that, owing to civic and other duties, he is unable to be with us.

A Member for Derby.

The President: I now have the greatest pleasure in introducing to you Sir Richard Luce, one of the Members of Parliament for Derby; and I take it as a personal compliment that he has come here. When I tell you he was in the House of Commons until 4 o'clock this morning, I think it shows a great example. We are very delighted to have Sir Richard with us, not only because he is an eminent Member of Parliament, but because—and this may appeal more to you—he is a very eminent surgeon. I will ask him to say a few words.

Sir Richard Luce: I take it as a great honour that you should have asked me to come here to-day. May I also say that I consider it a great honour to Derby that you should have elected my fellow townsman, Mr. Ferguson Bell, as the President of your Institution for this year? I am very happy to be associated with you to-day in supporting him on this great occasion, and wish you every success in your meetings.

Wrought-Iron Tubing Committee.

After Mr. W. M. Carr had replied to the discussion on his paper, which had taken place on Tuesday afternoon, the report of the Wrought-Iron Tubing Committee was submitted by Mr. R. H. Ruthven, Hon. Secretary of the Committee. See notice on p. 932.

International Commission on Illumination.

Mr. Robert Watson, of Doncaster (delegate of the Institution), presented the report of the sixth meeting of the International Commission on Illumination. See notice on p. 932.

Joint Refractories Research Committee.

The report of the Joint Refractories Research Committee was next taken. It was presented by Mr. J. P. Leather, the Chairman of the Committee. See p. 932.

Developments in Gas Calorimetry

Prof. C. V. Boys, F.R.S. (one of the Gas Referees), read a paper entitled "Developments in Gas Calorimetry;" and this, together with the discussion, is reproduced on p. 933.

Institution Gas Research Fellowship.

Prof. Cobb introduced the report of the Institution Gas Research Fellowship on "The Influence of the Inorganic Constituents of Coal in Carbonization and Gasification, with Special Reference to Nitrogen and Sulphur," by Mr. C. B. Marson, B.Sc. (Institution Gas Research Fellow), and Prof. J. W. Cobb, C.B.E., B.Sc., F.I.C. (Livesey Professor). See p. 932.

Town Gas for Motive Power.

On the resumption of the proceedings on Thursday morning, Sir Dugald Clerk, K.B.E., F.R.S., read a paper on "Town Gas for Motive Power." This and the discussion are given on p. 939.

The President: I have the pleasant duty of asking Sir Dugald Clerk to give this communication. Sir Dugald Clerk requires no introduction to any Institution in London, much less to the gentlemen whom I see before me, and I am quite sure that you will be delighted that he is able to come here and read a paper.

Economics of Gas Production on the Thermal Basis.

The final paper of the meeting was by Mr. George Evetts, and was entitled "The Economics of Gas Production on the Thermal Basis." This with the discussion will be found on p. 943.

The Balloting List.

The President: I have now to announce the result of the balloting. You will be glad to know that Mr. Botley has been unanimously elected President of our Institution. [Applause.] On your behalf, I offer to Mr. Botley sincere congratulations, and feel sure he will receive the full support, not only of the Council, but of all the members of the Institution. We hope that he will have a very successful and very pleasant year of office. The two Vice-Presidents are my friend Mr. Wilkinson, who resides not far away from Derby; as he comes from the Midlands, we know he is a good man. The other is Mr. Madden, who has been prominently connected with the Institution. He has taken a very active part in the proceedings, and I am sure we are all very pleased to know that he has agreed to become Junior Vice-President. For Auditors, we have our good friend Mr. Shoubridge, and Messrs. Wood, Drew, & Co. The Hon. Secretary, as you will all fully expect, is another old friend, Mr. Price. Mr. Price is invaluable. He tells the President what to do, and the President does it. The ordinary members of Council are Messrs. Armitage, Bennett, Copp, and Langford. We had a very good list of nominations. It took me a long time to decide for whom I should vote. In fact, I should have liked to vote for them all, because they would have made excellent members of Council. However, those who have not been elected I hope will allow their names to go forward on a future occasion, when they will doubtless be elected. I call upon our new President, Mr. Botley.

The New President.

Mr. C. F. Botley (Hastings): Mr. President and gentlemen, it is perhaps difficult in a few words to express one's feelings on an occasion like this; but I would first of all like to express a sense of the honour that I realize has been done me by those who in the first instance thought fit to nominate me, and now by you who have seen your way to support that nomination. Remembering that it has been my great privilege to work with my friend Mr. Bell and other of the Immediate Past-Presidents, I shall have some trepidation in endeavouring to emulate the work they have so splendidly done. But with your support—and without that, of course, it would be quite impossible to be a worthy President of the Institution—and the support of the Council, of which I am assured, I will strive to the utmost of my ability to uphold the high traditions and the great usefulness of the Institution.

List of New Officers.

President.—Mr. Charles F. Botley, of Hastings.
Senior Vice-President.—Mr. John Wilkinson, of Nottingham.
Junior Vice-President.—Mr. Henry D. Madden, of Cardiff.
Auditors.—Mr. Sydney Y. Shoubridge, of Eastbourne, and Messrs. Wood, Drew, & Co., of London.
Hon. Secretary.—Mr. W. E. Price, of West Chobham.
Ordinary Members of Council.—Messrs. Leonard J. Langford, of Tunbridge Wells; Harold E. Copp, of Hull; William H. Bennett, of Redhill; and Mr. Cecil Rhodes Armitage, of London.

Presidential Certificate.

Mr. Botley: I am not President yet; but by virtue of my office as Senior Vice-President, I have—it is the usual procedure—now to perform one of the pleasant duties which fall to the holder of the office. That is to put before the meeting in the best way I can an expression of our thanks to Mr. Bell, our President. [Applause.] Having had the great pleasure of being associated with my old friend Mr. Bell as one of the Vice-Presidents, I have had the opportunity of seeing from behind the scenes what our President has done; and I am sure that I am voicing the views of all of you when I say that he has fulfilled the expectations of those of you who know him. When Mr. Ferguson Bell some years ago stood aside, as was so very gracefully acknowledged by Mr. Henry Woodall at our opening session, in order that we might have the benefit of the services of the late Sir Corbet Woodall, he did so very willingly; and, as he himself has pointed out, the Institution have possibly been the gainers. We have had from him the benefit of extended experience, and he has perhaps been able to do for us what he could not have done years ago. We have had a most successful meeting; and I can assure you that, whatever help he has had—and of course Mr. Price, and the Secretary, and the members of Council have loyally rendered assistance to him—the initiation of practically everything has been due to the President. You know how he has drawn upon his knowledge of facts and people, and has secured at this meeting the attendance of distinguished guests. We have, I believe, derived a very great and lasting benefit from this meeting. But we are indebted to our President not only from the point of view of the gas industry; we must not forget the social side. As one who participated in that most enjoyable function last Tuesday, I must say that we owe Mr. Bell, Mrs. Bell, and their daughters very many thanks; and those of you who are going to Derby have a rich treat in store. Our President has rendered to the town of Derby and to the Company with which he is connected invaluable services; and I was very pleased to find that one, at any rate, of the Members of Parliament for Derby is of the same opinion. Doubtless both of them are; but I only heard one of them actually speaking. We are looking forward to a great day at Derby, and to the opportunity of congratulating our President there upon his actual work in his own town.

Before I sit down, I have another very pleasant duty to fulfil on your behalf. You know that it has within the last year or two been decided that there shall be given to the President a certificate, recording the fact that he has served the Institution in that capacity. No one, I venture to say, occupies the Presidential Chair without having a lasting recollection of the duties and pleasures which appertain to the office. But, Sir, there are those who come after us; and it is probably gratifying to our friends to have something tangible to remind them that we have done certain things. Memory, after all, is very short-lived. We pass away, and what we have done is apt to be very soon forgotten. Therefore it is very proper that there should be something to show that we have at some time or other been deemed worthy to be put at the head of the profession to which we belong. I have the greatest pleasure in asking you, Sir, to accept this certificate, and in addition I tender you our heartiest thanks for the invaluable services you have rendered to the industry and to us during the past year. It is not necessary for that to be seconded. [Applause.]

The President: I do very sincerely thank Mr. Botley for his altogether too flattering remarks with reference to

the services that I have been permitted to perform. My year of office has been an extremely pleasant one, and I have made a host of friends. I am delighted with the certificate, which shall be hung up in my study, to remind me of a very happy year. My wife is extremely pleased to know that our social function was a success, and she is looking forward to seeing at Derby a great number of you, accompanied by your ladies. I have received at the hands of the Council the fullest support, and also extreme kindness from the members of the Institution. This Institution, as is the case with similar bodies, depends very much upon what the members put into it; and the members during the past year have put a good deal of work into the Institution. This accounts, no doubt, for the success of our annual meeting. I can assure Mr. Botley he need have no fears in taking on the Presidency—he will receive the whole-hearted support, not only of the members of the Council, but of the entire Institution. I thank you most cordially for the kind way in which you have treated me during my year of office. If I have fulfilled your expectations, I am amply repaid.

Votes of Thanks.

The President: Before we separate, I should like to propose that the best thanks of the Institution be given to the Institution of Civil Engineers for their kindness in granting us the use of their House and this beautiful hall for our meetings. We are very glad indeed to get such excellent accommodation, which conduces greatly to the success of our meetings; and we thank them very sincerely.

Mr. F. P. Tarratt (Newcastle-on-Tyne): I second with pleasure this vote of thanks to the Institution of Civil Engineers. We much appreciate the kindness that they have extended to us.

Mr. John Wilkinson (Nottingham): I propose that the best thanks of this meeting be accorded to the Chairman and Directors of the Derby Gas Light and Coke Company for their invitation to visit the town, and for the hospitable arrangements that have been made for members and their ladies. We have seen what the President has done to entertain us here in London; and I am quite sure his Chairman and Directors will not be behind him.

Mr. H. D. Madden (Cardiff): It is a great pleasure to second that resolution. I think we are already indebted to the Chairman and Directors of the Derby Gas Company, for I feel sure that Mr. Bell has been backed-up by them handsomely during his year of office—which will certainly do a tremendous lot of good for the gas industry. Excellent propaganda work has been done.

The President: On behalf of the Chairman and Directors of the Derby Gas Company, whom it is my privilege to serve, I thank you very much for this vote, which shall be conveyed to the Board, who have been very kind to me during the past year. They told me when I became President of the Institution I was quite free to attend meetings in London and other places. They have, in fact, taken a lively interest in everything that affects the Institution. I am very glad that you have passed this vote, because at Derby the time will be fully occupied. We thought you would prefer to see the beauties of Derbyshire rather than to go through a toast list at the luncheon.

Mr. W. J. Smith (Bolton): It is my privilege to propose a vote of thanks to the National Physical Laboratory, the Gas Light and Coke Company, and the South Metropolitan Gas Company, for the very excellent arrangements made by them for the entertainment of the members of the Institution this afternoon.

Mr. W. S. Morland (Gloucester): I have pleasure in seconding that.

The President: There is another vote of thanks that I should like to propose. That is to Sir Henry Fowler, who used to be a member of this Institution, and is now Locomotive Superintendent to the L.M. & S. Railway. He was here yesterday, and you will see him again to-morrow at Derby. I know he is looking forward to renewing many old friendships, and he will show you an interesting locomotive works. I would also include the Carriage and Wagon Works of the L.M. & S. Railway, where you will see most ingenious labour-saving devices, and the Royal Crown Porcelain Works, to which the ladies are going.

Mr. Hubert Pooley (Leicester): I will second that, for I am quite certain we are going to have a most interesting day to-morrow.

Mr. C. Diamond (Barrow-in-Furness): As one of the younger members of the Institution, I deem it an honour to propose a vote of thanks to the Council, the Hon. Secretary, the authors of papers, the Research Committees, the Scrutineers, and the Auditors. It needs no words of mine to extol their labours.

Mr. J. H. Canning (Newport): It is a pleasure to me to second that, for I am sure a vote of thanks is due to those gentlemen who have co-operated with our President so excellently in making this meeting an unqualified success.

The President: I feel I must say how much I am indebted to Mr. Price, and to our Secretary, Mr. Dunn. Mr. Dunn has been laid-up for perhaps a fortnight; but he has been incessantly working at home, and the staff have helped me greatly. I have been in constant communication with Mr. Dunn all through the year, and have always found him most zealous and anxious to promote the welfare of the Institution in every possible way. I believe he has been our Secretary for about thirty years; and the arrangements he has made on all occasions have amply proved his capacity.

Mr. Wilkinson: The vote is an omnibus one, and, on behalf of the passengers travelling inside that omnibus, I thank you heartily for your kind expression of appreciation of the efforts that have been made on your behalf.

Mr. Price: I am much obliged to you for again electing me your Hon. Secretary; and while you do that I will do my best to give advice and guidance, if necessary, to the gentleman who happens to be the President for the time being. Your selection of President is, however, so excellent that really I find that the material I have to handle has already been modelled in a most proper manner, and all that I have to do is to see that it does not fall to pieces. [Laughter.]

Mr. Walter Dunn: I feel very much touched by what the President has said. I appreciate it immensely, and I am proud of being Secretary. I hope that I may continue to give the Institution satisfaction in that capacity. In the "Gas Journal," Mr. Bezant (the Editor) has been digging up old history; and I find that I am thirty years older than I was when I became your Secretary. We are, however, all growing older together; so I do not mind. I am a Scout Master, and am proud of it; and I think that helps to keep me young. Those who understand what a pleasure it is to see one's work succeed will understand my feelings when I tell you how proud I am to see our Institution flourish. Everyone connected with the Institution helps me; I could not do it alone. I make suggestions which are sometimes turned down and sometimes turned up, and become trumps. I have a suggestion for the new President, which I hope will mature.

Next Year's Meeting.

Mr. Botley: There is just one other subject I should like to refer to before the meeting disperses. I should not wish to be absolutely committal on the matter to-day; but there is just a possibility that the meeting could be held in Hastings next year. Nothing must, however, be done which would in any way interfere with the convenience of the members or the successful working of the Institution; and I should like, with the President's permission, to get some indication of the feeling of the meeting on the matter. Of course, if the meeting were held in London, there would be a possibility of an excursion to Hastings. Will somebody make a proposition? Well, as there seems to be no decided feeling on the matter one way or the other, you will have to leave it to the Council and myself to decide.

The President: That, gentlemen, concludes our business.

THE PRESIDENTIAL ADDRESS

OF

Mr. J. FERGUSON BELL, M.Inst.C.E., M.I.Mech.E.

General Manager and Engineer of the Derby Gas Light and Coke Company.

This being the first occasion on which it is my privilege to meet you collectively as President, I desire to take the opportunity to express my sincere thanks for the honour you have conferred upon me. The election to this Chair is the highest distinction which the Institution can bestow on those who have endeavoured to serve it faithfully and well. This Institution has attained to such a position that to be its President is to enjoy an honour which it is impossible to regard lightly; and I solicit the continued enthusiastic activity of members to promote the advancement of our industry by applying themselves to the solution of the many problems on which success depends. A year ago the Institution was 1005 strong; to-day we number about 1100. This indicates we are a growing body, representing a rapidly growing industry, with immense potentialities for the benefit of the community.

Honorary Members.

The honorary members number 21, a notable addition during the year being H.R.H. the Prince of Wales, who graciously consented to become an honorary life member. The Institution, as the technical head of the gas industry, is proud of this Royal recognition of service rendered to the community by one of the most important of our public utility services.

In addition, the proposed transfer of Mr. Charles Hunt —now the doyen of the gas industry—to honorary membership will, I feel sure, receive your hearty approval. Mr. Hunt for many years has been a distinguished member, and as an engineer, administrator, and adviser has won a prominent position. This transfer is to mark our recognition of his many valued services.

It was intended to confer a similar honour on one who for half-a-century was an outstanding and striking personality in the profession. I refer to the late Mr. H. E. Jones, who, as Chairman and Director of many gas companies, both at home and abroad, did invaluable service for the industry. The name of H. E. Jones will be long remembered as the donor of the "London" gold medal—shortly before his death he transferred securities to this Institution to provide for a gold medal to be presented annually.

Another name well known and deservedly respected is that of Alderman F. J. West, the present Lord Mayor of Manchester, who has done much to advance the scientific carbonization of coal. For many years the name of West has been a household word in the gas industry; and your Council decided to nominate Alderman F. J. West as an honorary member of the Institution—a course which I know the members will approve.

Institution Activities.

The activities of the Institution are indicated by our annual "Transactions," and by the proceedings of the Council as reported from time to time in the Technical Press They indicate steady progress, as the result of our deliberations and specialized investigations in conjunction with other organizations for co-ordination of scientific and industrial research, also independent investigations of essential problems to bring about a greater interfusion of theoretical scientific information and practical knowledge as to the best and most effective methods to elucidate those problems peculiar to our specialized industry.

Scientific research is the main, if not the only, source of fresh productivity in industry; and it is only by increased productivity that this country will find a way out of its present economic difficulties.

Education.

Our industry is of such a technical character that well-trained skilled technicians are absolutely necessary if we are to continue to carry on successfully the work which, year by year, becomes more important, as the figures I am about to give you conclusively prove.

Your Council for some time have had under consideration an Education Scheme, whereby those engaged in the industry will be afforded increased opportunities to equip themselves more thoroughly for their work. It has been approved by the Board of Education and City and Guilds of London Institute. Also I am happy to state it will generally receive the support of Local Education Authorities.

The Institution Education Syllabus has recently been issued. I commend this step, which may eventually be one of far-reaching importance, and ask your active co-operation towards making it a success. It is probable that membership of this Institution will, in the near future, be by examination. There are already 23 Technical Colleges giving "Course" instructions under the scheme. The number of students applying for examination shows a gratifying increase, being almost double that of the previous year. The Committee are to be congratulated upon the success that has attended their efforts, upon which they have spent much time and thought.

Importance of the Gas Industry.

The magnitude of our industry is indicated by the latest available Board of Trade returns relating to all authorized gas undertakings in Great Britain (for the year 1923) There are 790 company and local authorities' undertakings; the summary relating thereto is as follows:

Total coal, C.W.G., and other gas, millions c.ft.		259,819¾
Coal gas made, millions c.ft.		217,756¾
C.W.G. or blue gas made, millions c.ft.		38,347½
Coke oven and other gas, millions c.ft.		3,745¼
Coal carbonized, tons		16,460,632
Coke used for C.W.G., tons		906,717
Oil used for C.W.G., galls.		42,751,644
Coke and breeze made, tons		11,098,169
Tar made, galls.		181,962,574
Sulphate of ammonia made, tons		117,166
Consumers—Prepayment	4,231,243	
Ordinary	3,579,107	
		7,810,350
Length of gas mains, miles		40,984¼

The total nominal capital invested in the undertakings dealt with in this return is £165,210,254 (including loans raised by local authorities and sums repaid), an increase of £2,281,229 over the previous year. The receipts of the undertakings on revenue account amount to £67,576,358, and the expenditure to £56,593,900, which includes some 2½ million pounds for local rates—leaving a gross profit of £10,982,458—£444,758 less than in 1922, due mainly to the lower prices charged for gas. The recent slump in prices of all residual products will unfortunately mean an increase this year in the price of gas in most places.

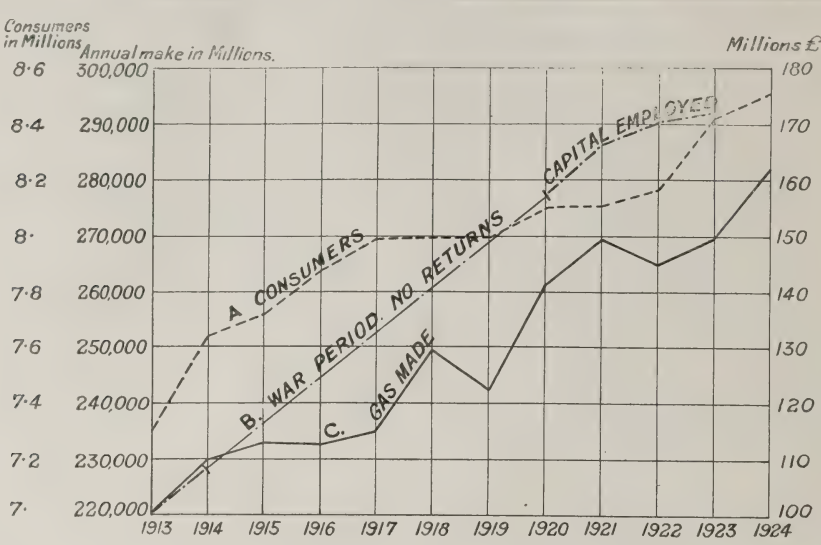
Striking Progress.

The striking progress of the gas industry in the United Kingdom since 1913 is shown by the diagram (Fig. 1) of statutory and non-statutory undertakings, giving the estimated total quantity in millions of cubic feet of gas made, number of consumers in millions, and capital employed in millions of pounds sterling.

It will be seen from the diagram that in the last five years the output has increased from 242 thousand million to 282 thousand million c.ft., an increase of no less than 40 thousand million c.ft., or more than the total gas made by the Gas Light and Coke Company, which is by far the largest gas undertaking in the world. Incidentally, it is interesting to record the fact that the Gas Light and Coke Company alone supplies more heat units than the combined output of all the electricity undertakings in this country.

The number of consumers has increased from about 8 millions to over 8½ millions. This increase alone is equal to the total population of two large cities such as Nottingham and Leicester.

The capital employed in the last three years has increased from £156,869,911 in 1920 to £173,470,766



CURVE **A**. *Number of Consumers in Millions.*

CURVE **B**. *Total Share & Loan Capital employed in Millions of £.*

CURVE **C**. *Annual makes of Gas in Millions of Cubic Feet.*

FIG. 1.—STATUTORY AND NON-STATUTORY UNDERTAKINGS, 1913-24.

in 1923. This is a growth of £16,600,855, or an average increase of just over £5,533,618 per annum.

This remarkable progress conclusively indicates that town gas in Great Britain is being used in an increasing quantity by an increasing number of consumers.

The Position in the United States.

The President of the American Gas Association has been kind enough to send me information as to the position of the gas industry in America. In 1903 the sales of manufactured gas totalled 105½ thousand million c.ft., and 124 thousand million c.ft. of natural gas; and in 1923 a new high record was reached of 370 thousand million c.ft. of manufactured gas and 760 thousand million c.ft. of natural gas. Thus in twenty years the sale of manufactured and natural gas in America reached the huge figure of 1130 thousand millions of c.ft., or about four times the make of the whole of the 790 authorized gas undertakings in Great Britain for the year 1923.

In certain districts in the United States natural gas is giving out; but its use in large quantities has so accustomed consumers to the many advantages and economies attending gaseous fuel that they will not return to solid fuel. There are 9½ million consumers, and new ones are being added in the United States at the rate of more than 400,000 a year. A notable fact is that, of the 964 undertakings, only 51 are operated by municipal authorities. A great expansion in auxiliary house heating by gas is taking place, and companies are putting in house-heating installations at the rate of about 10,000 a year. In some sections of the country they are supplying a large number of gas refrigeration machine installations. Annual sales of gas appliances aggregate 750,000 cooking stoves, 425,000 water heaters and 400,000 gas fires.

One of the principal factors responsible for the greatly increased sale of gas in America is the growing demand for gas in industry, where, according to the American Gas Association, gas is now used in more than 5000 separate and distinct ways. There was an increased consumption during the last decade of more than double, while its use for industrial purposes increased about 1000 p.ct.

In order to keep up with the demands by consumers, the gas companies spent $450,000,000 during 1923 on new works; and reports filed with the American Gas Association by its members show that the industry is enjoying the greatest expansion in its history. The results for 1924 are not yet available, but they are expected to show a large increase over the previous year. This is in a country with an abundance of natural water power, which has been called "white coal," rendering the generation of electricity in large quantities comparatively easy and inexpensive.

Cheap and Ample Supplies of Heat Energy.

Statistics are wearisome. I have quoted sufficient to indicate the importance and magnitude of the gas industry in this country and abroad. Contrary to the opinion of those unacquainted with the facts, its greatest growth has occurred during the past twenty years. Instead of declining in importance, it is now on the eve of its greatest expansion—given the same consideration as its competitors. The benefits that can be derived from one of the most important key industries in the country are being realized—whereby a substantial increase is obtained in the availability of the potential heat units of the coal used, and at the same time recovery of valuable bye-products so necessary to the country in time of peace. Their applicability and vital necessity were demonstrated in a remarkable manner during the war.

The provision of cheap and ample supplies of heat energy in the form of gaseous fuel can be best and most economically provided by the gas industry. In this connection, it is also a remarkable sign of the times that the British Commercial Gas Association have now on record a list of over 4000 trades in which gas is used, with an average of seven processes to each trade. This indicates the immense field there is for future development.

The gas industry has become one of the greatest co-operative efforts in the world. Through the National Gas Council, representing 841 company and municipal undertakings, being 88 p.ct. of the total make of gas in the United Kingdom, the industry has combined its forces for the benefit of consumers, employees, and producers, very ably guided by Mr. Milne Watson, D.L., the Governor of the Gas Light and Coke Company, assisted by an efficient staff.

Coal Conservation.

The importance of a more efficient utilization of our coal supplies, which are the foundation of this country's industrial position, demands that more attention should be given to this subject. Our national fuel resources are by no means inexhaustible. They are diminishing; yet our wealth of coal is being recklessly squandered in many directions.

The burning of raw coal in furnaces and open grates is extremely wasteful, resulting in unnecessary reduction in

our national coal resources, and also additional loss to the country by non-recovery of valuable bye-products, so essential for many industries. The baneful effect of smoke in most industrial centres is evident from the disfiguring effects, resulting in the drab and sordid appearance of many of our towns, and also in a reduction of available sunlight and ultra-violet rays, which not only adversely affects health, but involves an appreciable annual expenditure in making good the damage to buildings, &c.

The combination kitchen range for use simultaneously for heating, cooking, and hot-water supply is excessively extravagant in fuel and inefficient as compared with separate appliances designed for the special purposes. For instance, a coke-fired hot-water boiler uses only one-quarter of the fuel required by a range boiler. The combination of several functions in one range renders each separate function wasteful when used alone; and in ordinary practice they are not simultaneously required. For cooking and heating, gaseous fuel, used in properly designed appliances, effects a big saving in fuel and labour, with convenience and economy. The existing enactments are not sufficiently drastic to ensure even the curtailment of the evils arising from coal smoke and invisible sulphurous acid pollution. The time has arrived when the use of smoky fuel should be prohibited by legislation in the interest of health and to conserve our coal supplies.

The more extended use of gaseous fuel for trade and domestic purposes means a substantial increase in thermal efficiency, abating the smoke nuisance, and promoting better health, comfort, and convenience, less labour, and improved amenities of our towns. It is estimated that the extra cost for fuel and washing materials attributable to the smoky atmosphere in many industrial areas is equal to 7½d. per week per household, which for a town of a quarter-of-a-million inhabitants means a loss of over £100,000 per annum—and this without taking into account the contributory cause of general ill-health and squalid appearance of those smoke-laden districts.

Nowhere is coal treated with the same over-all efficiency as in the principal gas-works of this country; the thermal efficiency being well over 70 p.ct.

The total coal mined in the United Kingdom during 1923 was about 250 million tons. Some 186 million tons, or 75 p.ct., was for home requirements, of which 38 million tons were used for domestic purposes. The bulk of this is burned in open firegrates, giving a useful heat efficiency of only 15 to 25 p.ct., and worse still, serious pollution of the atmosphere by the production of coal smoke and noxious vapours, which are destructive alike to property and health.

For industrial purposes (other than used by railways, gas and electricity works, coke ovens, manufactured fuel, steamships, and exports), 72 million tons were used, making, with the 38 millions for domestic purposes, a total of 110 million tons, or 44 p.ct. of the total production. Of this, by our present lavish methods, it is estimated we waste some 40 million tons a year, which, at (say) 15s. per ton, means a loss of no less than 30 million sterling per annum to the country.

Gas and Electrical Efficiencies.

In view of suggested Government subsidies for the development of electricity, it is perhaps as well that I should inform the public how the matter stands between gas and electrical efficiencies. I do not desire to belittle the importance and progress of electricity, or to depreciate the valuable service performed by the electric supply industry, but rather to congratulate the electrical industry upon its progress. The handsome dividends it is able to pay its shareholders indicate prosperity, and no necessity for State aid.

The efficiencies of gas, coal, and electrical apparatus given below are the results of reliable experimental investigations with the most modern appliances:

Gas Appliances.

Gas Cooking Stoves of the Best Type

Hotplate boiling burner efficiency . . . . . 57 p.ct net calorific value
Oven cooking (gas at 8d. per therm) . . . . six 2-lb. loaves can be baked for less than 1d.

Gas Fires of Latest Type.

Radiant heat . . . . . 50–55 p.ct. net calorific value
Low-temperature convected heat . . . . 15–20 ,, ,, ,,
Flue heat for ventilation. . . . . Balance

Water Heating.

Geyser efficiency . . . . . 85–90 p.ct. gross calorific value
Circulator—boiler efficiency . . . . . 75–80 ,, ,, ,,

Furnace Operations.

Melting of yellow brass—pouring temperature 1000° C. . . . . } 2½ to 3 c.ft. per lb. (according to stand-by losses)
Steel annealing . . . . . 3000 to 4000 c.ft. per ton (according to size of articles)

Coal-Consuming Appliances.

Open Grate Fire.

Radiant efficiency . . . . . 15 to 25 p.ct.

Hot Water Supply from Coal Range Boiler.

Back boiler of range has a general efficiency of . . 11 to 12 p.ct.

Coal Range Oven.

Coal burned in the average commercial range, heat transmitted to oven . . . . . 2½ p.ct.

Total Efficiency.

Considering the coal range as a whole, it is estimated that the average efficiency is only about . . . 7½ p.ct.

Electrical Appliances.

Cookers of Best Type.

Hotplate boiling efficiency . . . . . 30 to 50 p.ct.

(according to whether the kettle is bright or black, and the care taken in switching-off the current before boiling actually occurs, allowing the water to boil as a result of the heat emitted by the elements after the current has been turned off).

Oven.

The best type of electrical oven will be found to use the same number of B.Th.U. as the best type of gas oven.

Water Heating.

Electrical immersion-heaters for boiling water have an efficiency of about . . . . . 90 p.ct.

Electrical Radiators.

If placed in the middle of the room, their heating efficiency is . . . . . 100 p.ct.

No allowance is made, however, for ventilation, which is essential, and with which they should be debited.

With electricity at the low price of 1d. per unit, and gas at 8d. per therm, heating operations, irrespective of the type of apparatus, cost from three to four times as much as corresponding operations performed by the aid of suitable gas appliances.

Carbonizing.

The freedom granted by the Gas Regulation Act, 1920, to introduce a method of charge based on potential heat energy supplied, in place of the volume basis, with reasonable liberty to enable gas undertakings to select those coals from the nearest mining centres, has resulted in renewed interest in the carbonization or distillation of coal for gaseous, solid, and liquid products. It is not my intention to differentiate between the various systems of carbonization or auxiliary processes; but I am of opinion that gas-works—more especially the larger ones—should, as far as possible, instal plant that will enable the undertaking to take full advantage of the prevailing economic market conditions, and so reduce the cost of their chief product. My experience during the war, and later with a three months' stoppage of coal supplies, was that ample plant which will produce either blue water gas or any quality of C.W.G., as auxiliary to the coal-gas plant and for emergency purposes, is invaluable.

I find from trustworthy data the thermal efficiencies obtainable per ton of coal or coke used in good ordinary practice with modern plant (not the results of special tests) by the various systems of carbonizing for the production of straight or mixed coal gas, and for C.W.G. or blue water gas per ton of good dry coke gasified, are as follows:

—	Quality of Gas. B.Th.U. per C.Ft.	Gas. P.Ct.	Coke. P.Ct.	Tar. P.Ct.	Heat Used and Lost in Manufacture. P.Ct.	Thermal Efficiency of Process. P.Ct.	Efficiency of Gas Production. P.Ct.
1. Horizontals. .	550	24·97	48·12	5·61	21·30	78 70	54·0
2. Do., with W.G. added . . .	500	28·17	42·12	4·89	24·82	75·18	53·2
3. Verticals with steaming, with W.H. boiler .	450	29·19	40·60	7·68	22·53	77·47	56·4
4. Blue water gas with W. H. boiler . . .	300	62·50	..	..	37·50	62 50	62 5
5. Carburetted W. G. with W.H. boiler .	500	68·00	..	1·75	30 25	69·75	69·2
6. Low-temperature carbonization.	700	13·61	55·33	10·87	20·19	79·81	40·3
7. Complete gasification . .	340	64 26	..	1 00	34 74	65·26	64 9

From these figures, it will be seen there is not much to choose, in regard to thermal efficiency, between the best horizontal and vertical carbonizing plants; but it is

necessary to bear in mind that a high number of therms per ton of coal used may be uneconomic as compared with a lower production by using cheaper grades of coal and smalls—especially is this the case with those undertakings near the collieries. This, however, must not be confused with thermal efficiency, which it should be the effort of all to increase, whatever the grade of fuel used.

For instance, at the Litchurch Works of the Derby Gas Light and Coke Company, by carbonization of cheaper coals and smalls, the over-all thermal efficiency last year was for a mixed gas 70·86 p.ct., and the average cost for coal, coke, and oil 4·48d., *less* residuals 3·34d., or 1·14d. net per therm, for gas of 503·8 B.Th.U. quality. The oil used was only 0·0423 of a gallon per 1000 c.ft., to enable a larger percentage of C.W.G. to meet sudden increases in the demand. The total gas made was 1362½ million c.ft., of which 20·93 p.ct. was blue or slightly carburetted water gas. Thermal efficiency *per se* is not always a reliable guide. The commercial values of ancillary products and their reflex action require to be taken into account in determining the cost of gas into holders. The collateral advantages of blue or lightly carburetted water gas—such as better control of the coke market, saving in capital charges on plant, lower costs for manufacture in repairs and maintenance, and emergency value, which depends to some extent upon local conditions—all require to be taken into account. The manufactured "mixed" gas often has advantages over the single product; and it is for each to study the controlling circumstances.

Complete gasification has not, so far, fulfilled expectations. The low calorific value of the gas produced renders it unsuitable for general distribution over large areas; and also the financial results compare unfavourably with other methods of carbonizing where bye-products return anything from 50 to 80 p.ct. of the cost of coal used. It is suitable as an auxiliary to the coal-gas plant. My experience indicates that it does not possess the same flexibility as blue or carburetted water gas.

It is impossible to exaggerate the importance of doing everything that is possible towards a better utilization of our coal supplies. Hence low-temperature carbonization is attractive, since it produces both gaseous and smokeless solid fuel useful for domestic and trade purposes, and also oil fuel, for which we are now dependent on imported supplies. It has not, however, so far been established by independent data that low-temperature carbonization has yet been placed upon a stable financial basis; and, as compared with high-temperature carbonizing, the efficiency as a gas-making process is low. Also all low-temperature processes depend mainly upon the commercial value of the solid and liquid products.

The admirable reports by the Fuel Research Board, giving the results of experimental investigations on high and low temperature carbonization under skilled scientific supervision, are of the greatest advantage; and I hope this valuable experimental work will be continued. It needs no words of mine to commend research by technical experts to ascertain the properties and suitability, and, by special treatment, to increase the availability of the potential thermal value of, our coal supplies, and so add to the nation's wealth.*

While on this subject, I desire to record great regret at the loss sustained by the death of Sir George Beilby, who was the greatest authority on the problems of fuel research. We owe much to him for active and valuable work extended over many years.

The reports of the investigations by the Research Sub-Committee of this Institution, in conjunction with the Leeds University, into the thermal and chemical efficiencies of manufacture of different grades of gas by various processes, deserve special praise; and the same applies to the investigations by the Refractory Materials Research Committee towards an improvement in the technique of refractories—placing at the disposal of all interested reliable data as regards thermal conductivity, fusion, expansion, contraction, and superimposed weight tests, all of which are so closely allied to successful carbonization.

* By the kindness of Dr. C. H. Lander, Director of Fuel Research, I am able to give as an appendix the experimental results obtained at the Fuel Research Station setting forth the thermal efficiencies for horizontal and vertical retorts, blue and carburetted water gas plants, and low-temperature carbonization. The difference between the thermal efficiency figures of gas production given by the Fuel Research Board and those given by me is mainly due to one set being the result of tests, and the other for actual working results.

Relation Between the Heating Value of Gas and Its Usefulness to the Consumer.

Closely connected with carbonization is the question of the relative usefulness of gases of different heating value and composition, which is not only important to the gas industry, but is one of more or less active controversy.

The investigations by the United States Bureau of Standards into the relative efficiencies of gases differing as widely as natural gas of 1100 B.Th.U. per c.ft. and various grades of manufactured gas from 725 to 500 B.Th.U., and also the reports by our Institution Gas Research Committee on gases from 500 to 240 B.Th.U., indicate that the relative usefulness of various gases for ordinary purposes is directly proportional to their heating value, and that there is no advantage in thermal efficiency for gas of lower heating value, but rather the reverse for gases of low calorific value with high inert content. Hence, within limits, with equal uniformity of quality and pressure, the volume of gas used will vary in inverse proportion to its potential thermal value.

The available heat units supplied in the form of gas are essentially the useful commodity for which the consumer pays, and a measure of the value received. This being so, it is essential that the method of manufacture shall be such as is calculated to deliver to the user the maximum number of heat units at the lowest possible cost, bearing in mind that the gas supplied is suited to the wants and requirements of the district, and the service given is such as will satisfy various users.

My experience indicates that gas of 500 B.Th.U. per c.ft. possesses advantages over that of a lower quality. The efficiency of utilization is somewhat higher, especially if the time required to perform a given operation is taken into account. There is the simplification of accounts and reduction of clerical work, by doing away with the second place of decimals; and, what is perhaps more important, it enables consumers readily to convert volume into therms. The conversion from thousands of cubic feet to therms (100,000 B.Th.U.), and *vice versa*, is simplified, as the thermal equivalent is 5; thus $\frac{1000}{5} = 200$, which is the number of cubic feet to a therm. For variation in price and calculation of dividends under the sliding-scale, a declared value of 500 B.Th.U. is obviously more convenient, as a penny per 1000 c.ft. is equivalent to 1-5th of a penny per therm, and cubic feet in cents as registered by consumers' meters divided by 2 equals therms.

From the National Gas Council return of Orders granted under section 1 of the Gas Regulation Act, 1920, up to Dec. 31, 1924, I observe the declared calorific standards are as follows:

Number of Gas Undertakings.		Calorific Value. B Th.U. per C.Ft.
4	..	270 to 375
66	..	400 to 440
135	..	450
55	..	460 to 470
60	..	475
45 (277)	..	480 to 490
172	..	500
28	..	510 to 600
Total . . 565	Average . .	472

Of the above, 76 have increased their declared value and 8 decreased it; and it will be seen that 277, or almost one-half of the total of 565, supply gas of from 474 to 500 B.Th.U. The tendency is upwards towards the 500 B.Th.U. standard, which seems to me to be in the right direction. It is of interest that the average declared value of the whole 565 undertakings is 472 B.Th.U.

I think there is much to be said for a uniform calorific standard of (say) 500 B.Th.U. for the whole country. This would simplify the adjustment of gas apparatus, and tend to reduce manufacturers' costs. Those who advocate supplying gas of low calorific value appear to ignore distribution costs, which are far from being a negligible item.

Power for Industrial and Other Purposes.

It is generally acknowledged that a modern gas engine is one of the most efficient prime movers available to-day; yet there has been a falling-off in their use of recent years, as a result of keen competition by electric motors—cur-

rent being sold at extremely low rates for power purposes. A formidable competitor is also the crude oil engine. There has been a marked decrease in the use of isolated steam power, except for large users or in special cases where steam is required for other purposes. The smaller steam engine, as regards convenience, availability, and costs, compares very unfavourably with gas, oil, or electricity.

Electricity is an efficient and convenient means of transmitting power. In some instances electric motors are no doubt more convenient and economical than any prime mover; but where the load is reasonably continuous, a gas or oil engine may effect a substantial reduction in running costs.

For crude oil engines, with a low price of £6 per ton for crude oil delivered by road tank-cars, the fuel cost alone is less than for town gas, unless supplied at a specially low rate; but this is only one item. The initial cost of an oil engine is greater than for a gas engine. There is the storage of oil and uncertainty as to its price, increased wear and tear, also higher costs for maintenance and attendance, all of which require to be taken into account when estimating over-all running costs.

Town gas possesses several advantages over producer gas or oil for power purposes. It is always available, there is no cost of storage or getting-in supplies, it is more reliable, needs less attention, and smaller initial outlay is required.

For power purposes it constitutes a desirable proposition, both for suppliers and users. The load factor is a

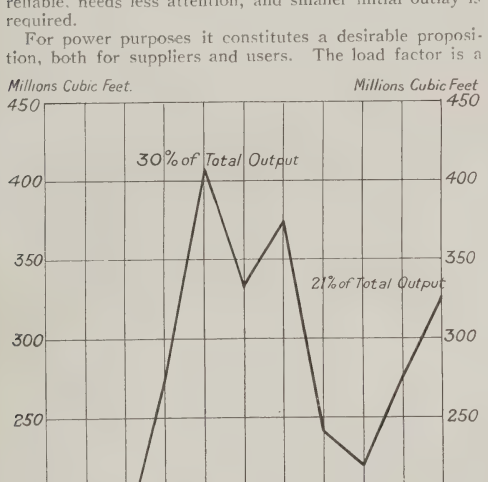


Fig. 2.—Derby Gas Light and Coke Company.

Chart showing gas used for Motor Power and Industrial Purposes, 1914-24.

good one; and it will pay gas undertakings to charge lower prices to encourage its extended use for power, to compete with oil and electricity. Severe competition will compel manufacturers to look more closely into production costs; and there are many industries where a modern type of gas engine will effect an appreciable saving over electric motors.

It is now over twenty years since the Derby Gas Company supplied and fixed gas engines on advantageous hire-purchase terms or sale outright; and the Board recently decided to let gas engines out on simple hire. The reduction in price charged for gas used in Derby for motive power and industrial purposes varies from 15 to 21 p.ct. (according to quantities used) below the initial price of gas. Fig. 2 indicates the large increase in the sale of gas for power and industrial purposes during the last ten years.

The decrease from the maximum of 407 million c.ft. in 1918 to 220 million c.ft. in 1922 was due to post-war effects. Output is now on the increase. Last year (1924) the quantity reached 326 million c.ft., so, notwithstanding continued trade depression, the increase during the last decade is 183 million c.ft. per annum, or 128 p.ct. In 1918 it was 30 p.ct., and last year 21 p.ct., of the total output. This indicates the importance of catering for power and industrial users. Both mean a regular demand all the year round.

In our case, the cost of gas for an engine of (say) 50 H.P. full load is only about one halfpenny per B.H.P. hour. I think you will agree this is cheap power, and that there is no necessity for the Government to subsidize power or other companies to enable manufacturers to obtain cheap energy, as the gas industry is supplying gas at prices which enable manufacturers to obtain power cheaply.

The reliability of modern gas engines, as compared with steam or electric, is at least equal, if not superior to, that of either.

The larger gas undertakings will be well advised to establish a power department under the charge of a skilled mechanic, competent to advise manufacturers, test, and carry out repairs and adjustments to gas engines. It cannot be expected that small gas undertakings can afford the expense of running a separate well-organized power department. I suggest that the larger works should co-operate with the smaller ones, so that the benefit and economy of using modern gas engines running on town gas may be extended over the country to the mutual advantage of producers and users.

I think it only fair to acknowledge that the great increase in the use of gas for numerous industrial purposes is due largely to the skill and enterprise of those who design and make gas apparatus, and to the praiseworthy propaganda work of the British Commercial Gas Association in making known the economy and advantages attending the use of gaseous fuel—work which is actively supported by gas undertakings. I am mindful of the excellent work done by the Society of British Gas Industries, and think this Institution and that Society might become more closely associated with advantage; an interchange of views must always be beneficial to both sides.

Smokeless Gas Coke.

The mild winter in Northern Europe and consequent diminution in demand for coke have led to accumulation of stocks throughout the country. Undertakings which in normal circumstances rely to a large extent on the export market for coke are naturally the hardest hit; but the seriousness of the coke position throughout the industry calls for united action with a view to promoting an increase in its use for industrial, as well as for domestic, purposes.

It is not sufficiently appreciated by industrialists, and especially by those who are genuinely concerned and anxious to mitigate the smoke nuisance, that, in addition to its valuable smokeless characteristic, gas coke, either by itself or in admixture with small coal or slack, can and does effect economy in steam raising. Whereas coal slack in normal every-day boiler practice will evaporate on the average about 6 to 7 lbs. of water per pound of slack, coke of good average quality will evaporate upwards of 9 lbs., and will in addition afford complete relief from the consequences of smoke emission.

Proof of the growing appreciation of the inherent advantages of gas coke as a fuel is evidenced by its extended use on the "Sandwich" system at electricity supply and tramway power stations. A contract recently concluded between the London County Council and the South Metropolitan Gas Company (who invariably lead the way) provides for supplies of coke to the Greenwich power station at a rate approximating 50 p.ct. of the total weekly fuel consumption of the station—viz., 3000 tons per week.

The practical consummation of the ideal of closer co-operation, in the national interests, with our electrical friends, is here clearly indicated; and a wider adoption of the "Sandwich" system, which has rendered the use of coke at power stations not only practicable but economical, as compared with coal alone, would tend not only to foster such co-operation in the interest of all concerned, but to remove, at least to some degree, the stigma that unavoidably attaches to the complete destruction of coal when used as fuel in its raw state for the generation of electrical power.

While the use of pulverized coal as fuel at power stations tends towards improved efficiency of combustion, it does not justify in the least the use of raw coal; and while the pulverized coal system may be regarded as an important development in power station equipment, the recent adop-

tion of the "Sandwich" system of coke firing at an important new power station (Barton) brings the latter system right abreast of modern boiler-house practice.

The promotion of domestic uses for coke will, however, appeal to most gas undertakings; and if constant and abundant hot water is admitted to be indispensable in modern domestic and personal hygiene, then a coke-fired boiler must be regarded as a necessary adjunct to the modern household. Herein lies an immense field for expansion.

I should like to commend the propaganda work of the London Coke Committee and their very able fuel expert, Mr. E. W. L. Nicol, Assoc.Inst.C.E., M.I.Mar.E. I think that provincial gas undertakings might with advantage combine to do something in the same direction. All gas undertakings should, by advertising in the local Press, and by circulars, draw attention to the merits of this solid smokeless fuel, and see that facilities are afforded for delivery in small quantities, by means of bags, &c. I observe from "Field's Analysis" for 1923 that the income from coke and breeze of the three Metropolitan Gas Companies was £2,738,108—equal to 2·445d. per therm, or 12·61d. per 1000 c.ft. on gas sold, which indicates the importance of this source of revenue, and the necessity for doing everything possible to promote and popularize the use of coke.

Proposed Government Assistance to the Electric Supply Industry.

I do not, as a rule, refer to a competitive industry; but the proposals put forward that Government assistance should be given to bring about the reorganization and expansion of the electricity supply industry by an issue of Electricity Bonds to an ultimate total value of £50,000,000, guaranteed by the Government, is so manifestly unfair, not only to the gas industry, but to many other industries, that I desire to enter an emphatic protest against any such one-sided scheme to which there are many objections, both on principle and as regards its application.

There is ample room for both gas and electricity in their own spheres; and before any legislation is introduced, the country ought to be made aware of the whole facts, and an answer given to the very important question: To what extent can power and heat and light be cheapened by the conversion as now practised of the potential energy of coal into electric current, or by the more logical way of distillation for separation into gaseous, solid, and liquid products?

It is an admitted fact that the highest thermal efficiency in the utilization of coal is achieved by the gas industry. The efficiencies of gas and electricity in production, distribution, and utilization are as follows:

—	Number of Heat Units Delivered to Consumer per 100 Heat Units in Coal Used — Thermal Efficiency of Manufacture and Distribution.	Number of Heat Units Converted into Useful Work by Consumer per 100 Heat Units in Coal Used.			
		For Heating Rooms.	For Heating and Boiling Water.	For Cooking by Oven.	For Power.
Gas: Average present practice	47·5	29	35	6·2	11·2
Electricity: Average present practice	9·5	9·5	4·8	2·1	8·65

From these figures, it is evident that the maintenance and development of the gas industry are essential in the interest of fuel conservation, apart from other questions.

The proposal for giving an artificial stimulus to the electricity supply industry by means of Government financial assistance should, I think, be considered as to the probable effect of this unprecedented departure:

(1) On national grounds.
(2) From the point of view of:
  (*a*) The electricity supply industry.
  (*b*) Municipal enterprise.
  (*c*) The gas industry.

(1).—National Grounds.

Artificial stimulus to any industry by means of State aid is without precedent, and is essentially contrary to the financial or fiscal policy of this country. State aid to any particular industry constitutes a form of domestic internal protection at the expense of other industries. Coal is our great national asset; and I have already shown that the highest thermal efficiency in the utilization of coal is obtained by high-temperature carbonization.

Cheap electricity is not a panacea for all industrial ills. I find that in most industries the percentage for power costs, as compared with total production costs for materials, labour, rates, and overhead charges, varies from 1 to under 5 p.ct. only—*e.g.*, engineering 2·95, motor cars 2·40, printing 1·90, and paint 1·95 p.ct. For malleable iron castings it is 3 p.ct. only of the total cost per ton. Hence, it will be seen that the plausible cry that industry will revive if only manufacturers can obtain motive power at abnormally low rates is misleading, and will only delude those who put their trust in doctrinaire promises.

It should not be overlooked that the gas industry itself employs five men for every one engaged in the electricity supply industry on the same amount of work done.

Government money spent on the development of electricity may be wasted on uneconomic and unremunerative schemes. The electrical industry itself is sufficiently prosperous to pay for any schemes which would result in a fair remuneration on the capital expended. The pre-war and post-war dividends paid by the Metropolitan and Provincial electric supply companies amply prove this.

Further, it is quite probable that within the next few years a gas turbine will be perfected which may render obsolete the most efficient methods for the generation of electricity in use to-day, and may well make long-distance distribution of electrical current an unnecessary and wasteful practice.

(2).—From the Point of View of the Electricity Supply Industry.

Great doubt is felt by a large body of electricians themselves as to whether any scheme of Government financial assistance can be to the ultimate benefit of the electricity supply industry. The inevitable result of any State-aided uniform scheme for the supply of electricity would be to stereotype and crystallize electrical practice. Future progress would be impeded, cheapness would be retarded, and the industry and the nation would alike suffer.

(3).—From the Point of View of Municipal Enterprise.

The setting-up of super-power stations by means of Government financial assistance must entail the closing-down of a large number of municipal generating stations, thereby depriving the municipality of the control of its own works. Financial assistance granted by the Government to the electricity supply industry must tend to jeopardize municipal enterprise in probably its most successful department—namely, that of gas supply. In this respect, it is noteworthy that about 40 p.ct. of the gas supplied in Great Britain is provided by municipal undertakings, which are justified in expecting that Parliament, which created them, will take no steps to hamper or harass their activities in the future.

(4).—From the Point of View of the Gas Industry.

On these grounds I submit:

(1) That no case has been made out for any subsidy being granted to the electricity supply industry.
(2) That if the Government is determined to adopt a policy of national subsidies, then all rival and competitive trades and industries should receive like subsidies on the same terms and conditions.
(3) That such subsidies should take the form of loans repayable with interest over a period of years by the industry or undertaking assisted, in a similar manner to loans (sanctioned by the Government) to municipal trading departments.

Conclusions.

In the foregoing remarks I have very imperfectly endeavoured to draw attention to some of the more salient matters, confining myself chiefly to those which seem to me to have the most bearing upon the future of our industry.

Labour-aiding appliances do not, as fallible prophets visualized years ago, result in reduction of employment, but in increased output. The descendants of these same prophets think they hear, in the hum of the big electro-turbo generators, the knell of our industry. They are mistaken. Like many other businesses, the gas industry really began to expand when it had to hustle for business. The possibilities in the use of gas are greater than ever; and

I look with confidence to a large extension in its applications both for industrial and domestic purposes.

Before I conclude, I desire to thank those who responded to my recent appeal for increased support to our Benevolent Fund, which really merits more support than it receives, and should rest on a wider basis of annual subscribers. There is a well-known saying, "Charity begins at home." It cannot better begin than in assisting to help those of our calling and their dependants who, through circumstances beyond their control, are no longer able to provide for themselves. I venture to put this before you, not as a duty but a privilege of those who possess the means to help those less fortunate.

APPENDIX.

Thermal Values of Gas Coals and Coke, and Thermal Efficiencies of Horizontal and Vertical Retorts, Blue Water Gas, Carburetted Water Gas, and Low-Temperature Carbonization, compiled by the Staff of the Fuel Research Station, by permission of the Director of Fuel Research.

Thermal Value of Gas Coals and Cokes.

The thermal value of coals varies with the nature of the coal. In gas coals from the same district the variation is normally small when reckoned on a dry ash-free basis.

—	Moisture.	Ash.	Gross Calorific Value.	
			B.Th.U. per Lb.	Dry Ash-Free Coal or Coke.
Coal—				
Durham	1·5	7·0	14,040	15,340
Yorkshire	1·5	7·0	14,030	15,330
Nottinghamshire, Derbyshire	Survey of this coalfield has not yet commenced, and figures are not available.			
Coke—				
Horizontal (1)	1·5	10·2	12,570	14,230
Vertical (2)	0·6	10·7	12,500	14,100
Low temperature (3) (Volatiles 8 p.ct.)	2·5	8·0	13,200	14,750

(1) Durham coal.
(2) Yorkshire coal.
(3) Since the ash in low-temperature coke becomes very apparent on combustion, this commodity is not likely to appeal to the average consumer unless care is taken to reduce the ash content of the raw material by washing, if necessary. The figure given is based on an ash content in the coal of 6 p.ct.

Horizontal Retort Practice.

DURHAM COAL.

	Therms.
Gas	71·8
Coke (total)	207·5
Tar	18·3
	297·6

Taking coal as 14,040 B.Th.U. per lb., or 314·5 therms per ton, the thermal efficiency is 94·5 p.ct.

The carbonizing efficiency, taking 32·0 therms of coke consumed on the retorts, is 84·4 p.ct.

Vertical Retort Practice.

In order to obtain the necessary 500 B.Th.U. standard specified, steaming to the extent of about 8 p.ct. only would be possible with (say) Yorkshire coal:

	Therms.
Coal	314·3 (ash 7·0 p.ct., moisture 1·5 p.ct.)
Coke (total)	186·5
Gas	90·0 (500 B.Th.U. per c.ft.)
Tar	20·0
	296·5, or 94·3 p.ct.

These are Fuel Research Station results; and it is not possible to allocate directly the amount of heat required for auxiliary operations. These can, however, be deduced from the Gas Institution results obtained at Uddingston:

Fuel to setting . . . . . 30·2 therms per ton of coal
Fuel to raise 8 p.ct. of steam . 2·9 ,, ,, ,,

In a modern plant equipped with a waste-heat boiler, sufficient steam could be raised to supply the retorts, the tar, &c., pumps, and probably the gas exhausters.

The net efficiency of the system would therefore be 84·7 p.ct.

Without a waste-heat boiler this figure would be reduced to about 81·5 p.ct.

Blue Water Gas.

The following figures are taken from Fuel Research Station experiments, with calculated allowances for fuel consumed in the process. Figures taken from the Gas Institution work are also shown for comparison, since these were obtained during the actual commercial operation of a plant.

—	Fuel Research Station.	Gas Institution.
	P.Ct.	P.Ct.
(1)—Efficiency of generator	57·81	50·2
Lost in steam raising	3·15	..
Power to blower—		
(1) Electric fan, 14 p.ct. efficiency	2·15	..
(2) Steam turbo blower	6 25	..
Net efficiency of plant—		
(1)	54·9*	
(2)	52 8*	46·3
(2)—If the plant be equipped with a waste-heat boiler, the following efficiencies arise—		
Efficiency of generator	62 4	53·7

* This net efficiency does not make allowance for extra services such as transport of coke, &c.

Carburetted Water Gas.

The following figures are taken from the report by the Gas Investigation Committee. The Fuel Research Station have no data on this process.

Efficiency of water gas generator (excluding steam). . 53·7 p.ct.
Efficiency of carburetted water gas production . . . 68·0 ,,

The efficiency of the "cracking" process was, in these experiments, about 76 p.ct. This agrees with figures supplied to us from time to time by other investigators.

The steam generated in the waste-heat boilers is sufficient to supply all requirements.

Low-Temperature Carbonization.

FUEL RESEARCH STATION.

Vertical Cast-Iron Retorts (630° C.).

	Therms.
Coal, 1 ton	280·0 (moisture 6·6 p.ct., ash 8·9 p.ct.)
Coke, 13·7 cwt.	192·2 (ash 11·0 p.ct.)
Gas, 6970 c.ft.	45·2 (648 B.Th.U.)
Tar, 14·6 gallons	24·9 (sp. gr. 1·07)
	262·3, or 93·7 p.ct.

(1) Fuel gas to setting, 29·2 therms (2500 c.ft. of water gas per hour, 0·25 tons per 4 retorts per hour).
(2) Steam to retorts (up to 10 p.ct.) from waste heat.
(3) Crushing of coal, 1·0 therms.

Net efficiency, allowing for (1) only . . . = 83·2 p.ct.
for (1) and (3) . . = 82·9 ,,

BARNSLEY.

	Therms.
Coal, 20 cwt.	305·5 (moisture 5·2 p.ct., ash 4·5 p.ct.)
Coke, 13·92 cwt.	214·0
Gas, 5620 c.ft.	39·6 (scrubbed)
Tar, 18·62 gallons.	32 7
Spirit, 1·78 ,,	3·1
	289·4, or 94·8 p.ct.

Fuel to settings was excessive during the Fuel Research Station test, and should be reducible from 41·8 to about 35 therms per ton. All steam necessary could be supplied from waste heat.

Net efficiency, 83·3 p.ct.

SOCIAL EVENTS.

THE PRESIDENT'S RECEPTION.

To the President and Mrs. Ferguson Bell some 600 guests are indebted for open-handed hospitality and entertainment at the reception and dance they offered at the Connaught Rooms, Great Queen Street, on the Tuesday evening. Mr. and Mrs. Ferguson Bell, with their daughters, stood for an hour receiving their many guests; and they had a smile and a word of welcome for all. Mrs. Bell carried a beautiful bouquet of yellow roses, presented to her by the Midland Association of Gas Engineers and Managers, and the Misses Bell had been the recipients of sheaves of carnations from Sir Arthur Duckham.

To mention the names of the many distinguished guests would overtax the space allowed in a technical journal for the recording of a social event; but it is our custom to select those who were present as representing the industry's organizations. They were: Of the Institution of Gas Engineers: Mr. C. F. Botley (then Senior Vice-President); Mr. John Wilkinson, O.B.E. (Junior Vice-President); Mr. W. E. Price (Hon. Secretary); and Mr. Walter T. Dunn (Secretary). Of the National Gas Council: Mr. Ernest J. Fottrell (Joint Manager). Of the British Commercial Gas Association: Mr. F. W. Goodenough (Executive Chairman) and Mr. W. M. Mason (Manager). Of the Society of British Gas Industries: Mr. B. B. Waller (Chairman of Council); Sir Alfred Mond, the President, was unavoidably absent, but communicated his deep regrets and good wishes to Mr. Bell. Mr. W. J. A. Butterfield represented the Gas Referees, and Prof. John W. Cobb, C.B.E., the University of Leeds. Mr. Hermann L. Shepherd, Lt.-Col. W. R. Glover, C.M.G., D.S.O., and Mr. James Bridge represented, as their W.M.'s, the Evening Star, the Murdoch, and the Northern Star Lodges respectively. There were present many Past-Presidents of the Institution, including Mr. Samuel Tagg, J.P., Mr. Bell's immediate predecessor; and the District Associations were strongly represented by their officers. "H. E. J." was sadly missed, but all found pleasure in greeting his son, Mr. Frank H. Jones, Vice-President of the South Metropolitan Gas Company. Mr. Reginald Clarry, M.P., was there; but the President of the Institution of Electrical Engineers was detained by the annual meeting of that body in the Midlands, and wrote expressing regret and the greetings of the sister Institution.

Mr. Ronald Glover, M.C., was assiduous in his duties as Master of Ceremonies, and the thanks of all are due to him, as to the following gentlemen who acted as Stewards: Messrs. E. J. Fottrell, H. H. Gracie (Edinburgh), H. D. Madden (Cardiff), W. E. Caton (Oxford), F. H. Robinson (Harrogate), P. G. G. Moon (Bournemouth), F. A. West (Newark), and J. D. Smith, J.P. (as the representative of Ireland).

In spite of the following of last year's excellent precedent of holding the reception at the Connaught Rooms instead of Prince's, the large company overflowed the great banqueting hall, and Mr. Ferguson Bell thoughtfully arranged to have the smaller reception room thrown open as a buffet and sitting-out room. Dancing began at 9 o'clock, and continued, with a short interval, till midnight; the band acquitting themselves nobly in rendering popular dance music with vigour unabating in spite of the warmth of the evening. Nearly everybody danced, and the whole proceedings went with a swing which culminated in an eightsome reel rendered by three sets with characteristic energy, and which reminded many of us Sassenachs that dancing in its truest sense is an art not totally obliterated.

Congratulations to Mr. and Mrs. Ferguson Bell upon the excellence of their generosity and arrangements!

THE LUNCHEON.

The President of the Board of Trade as Chief Guest.

At the close of Wednesday morning's session, a large party repaired to the magnificent premises in Pall Mall of the Royal Automobile Club, in response to an invitation by the President, Vice-Presidents, and Council of the Institution, to meet at luncheon the Right Hon. Sir Philip Cunliffe-Lister, K.B.E., M.C., M.P., the President of the Board of Trade. Many who are well known to all in the industry, and beyond it, were there; but of them it is possible here to mention only a few. The President (Mr. J. Ferguson Bell) occupied the chair; and on his right were Sir P. Cunliffe-Lister, Dr. Charles Carpenter, C.B.E., Mr. R. G. Clarry, M.P., Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., Mr. Henry Woodall, Mr. Thomas Goulden, Mr. Thomas Hardie, and Mr. H. C. Honey. To the President's left sat the Right Hon. J. H. Thomas, P.C., M.P., Mr. W. Woolley, Mr. D. Milne Watson, and Major-General Sir R. Luce, M.P. The vice-chairs were occupied by the Vice-Presidents of the Institution (Mr. C. F. Botley and Mr. J. Wilkinson). Among the visitors, also, were Presidents, &c., of kindred associations. After the Loyal Toasts had been honoured at the call of the Chair,

Four Square in Defence of the Empire.

The Right Hon. J. H. Thomas, who had to leave early to fulfil another engagement, said their Chairman and the President of the Board of Trade had consented to his toast taking precedence. As a matter of fact, it really ought to take precedence, because it was the toast of "Success, Prosperity, and Long Life to the Institution of Gas Engineers." Although "long life" was not included in the toast as printed, he had deliberately added it, as a sentiment to which they would drink with enthusiasm. He was really in some difficulty to know quite the reason that would warrant them in accepting him as a fitting person to propose the toast; but after all, it might not be hard to justify it. They were gas producers; while the politicians were gas distributors. [Laughter.] He was also one of the Members of Parliament for Derby; and whatever might be said about the gas undertakings in other parts of the country, they must believe him when he told them that Derby of necessity stood supreme. This was evidence of their wisdom in appointing as their President a Derby man. Now, he had been asked to propose "Prosperity to the Institution"—an Institution that was not only represented there by distinguished men in the profession, but that included in its membership people from overseas—in fact, from all parts of the world. He would say to the Overseas Dominions: "We welcome you among us as grown-up sons and brothers." Then he would say to their foreign colleagues who were represented: "We welcome you for what you can contribute to the world in science and knowledge." Because, after all, the real object of that Institution—the one thing above all others that justified its claim to support—was to encourage the acquisition by young men of fresh knowledge. This was why he thought it was the duty of all to give their blessings to the Institution. Referring to politics in this country, he would just like to say one thing to their Colonial and foreign guests—the failure to keep in mind which sometimes led to confusion of thought and difficulties that would be avoided if it were remembered. It was this: "Whatever may be the political differences—and they are many—whatever may be the political fortunes of parties, whatever may be the interests of class or creed, in this country, the past history of our country proves, and everything that we see to-day demonstrates, that there is no varying of the policy that, however much we may quarrel among ourselves, when the real fundamental issue of the Empire and its welfare is involved, they will always find us standing four square in defence of that Empire." ["Hear, hear."] Because the members of the Institution had an opportunity of meeting together, of exchanging views, of understanding one another better, and of pooling their knowledge (which was not knowledge of benefit to them alone, but must always be of benefit to the community), he was delighted to be present among them and propose the toast of "Success, Prosperity, and Long Life to the Institution"—with special emphasis on the words "long life."

Out for Efficiency.

The Chairman, responding, expressed high appreciation of all the kind things that had been said about the Institution and the gas industry by Mr. Thomas. Public utility services were not always appreciated as they deserved to be. The efficiency of their industry was what they were out for. They were out to serve the public by giving them an ample supply of gaseous energy at the lowest possible price. He ventured to think such social functions as the one they were then enjoying were helpful to all parties, because misunderstandings often arose through misapprehension of facts; and it was well that people should realize there were two sides to most questions. They were glad to welcome Sir Cunliffe-Lister, not only as President of the Board of Trade, but for his own personal sake. They were also pleased to have with them several other distinguished visitors. The Institution dated back to 1864, so that it was a fairly old one. An education scheme had been introduced, so that those who were to come after them might be suitably technically equipped to perform the duties that they would be called upon to fulfil. They as an Institution were anxious to maintain the gas industry; and, as he said, they were out to make it, if possible, still more efficient. The gas industry was full of vitality instead of being, as some people thought, in a state of decay; and he ventured to declare that the next few years would witness still greater development. He had referred in his address to the great development of gas in the United States of America; and the same could be said of the industry on the Continent of Europe and in other parts of the world. The gas industry of this country, with its allied trades, had a capital of something like £200,000,000,

and provided practically permanent employment to about 125,000 men—which in these days of unemployment was something to be proud of.

SELF-HELP AS A REMEDY.

Mr. D. MILNE WATSON said it was with great pleasure that he rose to give the toast "Trade and Industry," coupling with it the name of the President of the Board of Trade, Sir P. Cunliffe-Lister. They were very pleased indeed to have him among them. At the present moment the trade of the country was going through a very bad time, and unemployment was rife. It was three times what it was before the war, and everybody was looking for a remedy. Personally, he did not believe that any miracle was going to take place to help them out of their difficulty; to his mind the remedy for the present troubles was self-help ["Hear, hear"], coupled with lower taxation. If employers and employed were prepared to make sacrifices, he did not believe the country would be long in getting trade started again on a pre-war basis. The trouble was that everyone was looking for help from outside. It rather reminded one of the family in financial stress, who sat round a table to discuss matters. The son said: "My allowance must remain the same." The daughter said: "I must have my motor-car and horses as usual." And the father ended up by saying: "I must have cigars and wine as usual." There was nothing to be said about the mother; she was always self-sacrificing. What he had portrayed was very much the position of industry at the moment. No one—either one side or the other—wanted to give up anything. But he felt perfectly certain that, until this idea was got rid of, they were never going to get straight again in this country. No speech from him would be considered complete without some reference to Scotland; and he would like to ask them: "Do you think that little tribe north of the Tweed would have come into the position of being the rulers of the world if they had not been prepared in the early days to make great sacrifices for education—if they had not been prepared to work in the summer time at the harvest, in order, during the winter time, to be able to go to the school and college? Do you think they would be occupying the position they now do all over the world if they had waited for the Carnegie Trust for education?" In a little fable by Æsop, a farmer said to his sons: "I am going to leave you a field, and in that field is hidden great treasure. If you go there, you will find that treasure." The old man in due course died, and his sons got pickaxe and spade and started to dig over the whole field, expecting to find gold and silver treasure buried in the vineyard. They never found it; but after working and cultivating, they had the best vineyard in the country, and had their reward in bountiful crops. That was the moral for this country. They must not go looking for hidden treasure. It was by work alone that this country, and its industry and trade, would get right. They were thinking too little about self-help, and too much about what Government assistance they could get.

THE CASE OF ELECTRICITY.

Take this illustration of electricity. It was said by many learned professors and many politicians that too little electricity was used in this country, and that it was too dear; and they compared the amount of electricity utilized in this country with other countries, and found that in Switzerland the figure was 700 units per head, Canada 612 units, the United States 472 units, France 147 units, Germany 141 units, and Great Britain about 139 units. It would be noticed that a certain group of countries—Switzerland, Canada, Norway, the United States, and Sweden—used a large amount of electricity, and that the three countries he had last quoted—France, Germany, and Great Britain—consumed about the same quantity. What was the reason for this? That the first group had water power, and could use this to generate electricity; whereas in this country, Germany, and France there was coal, and these coal countries were developing on a line of their own. They were not only turning a certain amount of coal into electricity, but also turning it into gas, of which they used much more, because it was the natural way in which to utilize the resources of the country. The other point was that it cost too much in this country. Well, electricity in many districts of this country cost half what it did in Switzerland. Electricity on the North-East Coast was equal in price to Chicago—a startling figure; yet in spite of this they were told that, if they obtained Government assistance and organization for electricity they were going to have less unemployment and smokeless towns. As for less unemployment, with equal rates for electricity, in Chicago trade was booming, while on the North-East Coast it was more depressed than anywhere else. How could they think that electricity had anything to do with it at all? If electricity had been given away, it would not have preserved many recent contracts for this country. It was hunting a "will o' the wisp" to say that electricity was going to solve the unemployment problem of this country. They had been told at Barking that electricity was going to purify the air. Gas had already purified the air—that was his answer. Going along King's Road, Chelsea, he happened to pass the Fulham Gas-Works, and there the air was clear and bright. Near by was the Lots Road Power Station, with the chimneys belching forth smoke. So much for the purification of the air.

LOW-TEMPERATURE CARBONIZATION.

Next he came to the question of low-temperature carbonization. It had been stated in the papers that if only the Government would give £10,000,000 low-temperature carbonization would save the country. Did they seriously think that the manufacturers and the owners of private capital in this country were such fools that if they thought £10,000,000 could have made a commercial success of it, they would not have invested it in low-temperature carbonization? Yet, apparently, there were a large number of people who believed that £10,000,000 of Government money could make a desert blossom, whereas £10,000,000 of ordinary capital could do nothing.

BRITISH TAR FOR BRITISH ROADS.

Then there was another matter of which he had read in the papers that morning. When they had a man like Sir Henry Maybury, occupying a high position in the Ministry of Transport, referring to the use of bitumen for roads, and then going on gratuitously to say: "As for tar, it sticks to everything except the road," was this a helpful thing to British industry? ["No."] It was a scandalous thing. One of the highest officials in a Government Department deliberately crabbing one of the biggest products of this country, and throwing his weight on to the side of an imported substance which cost twice as much! If they wanted to help the trade of this country, why did not they say: "Use British tar for British roads"—except for the 4 p.ct. of roads which lay along trout streams, if they liked? Even in London, trying to make them use bitumen instead of tar! It was a scandal. Could they imagine any body of Germans or Frenchmen sitting round a

LEFT TO RIGHT at Top Table: Mr. Reginald Clarry, M.P., Dr. Chas. Carpenter, C.B.E., Sir Philip Cunliffe-Lister, Mr. Ferguson Bell, Mr. J. H. Thomas, M.P., Mr. Wm. Woolley, Mr. Milne Watson, D.L., and Major-Gen. Sir R. H. Luce, M.P.

table, who would scheme how to get a foreign substance used instead of their home commodity? He would not have referred to the matter in such a way had he not felt that this adoration of what came from abroad did more harm to British trade than anything else at the present moment. [Applause.] "I believe," concluded Mr. Milne Watson, "that if we would only put our backs into it—each one and everyone—employer and employed—this country would win through. I cannot believe anything else. I couple with the toast the name of Sir Cunliffe-Lister; and I hope he will remember that gas is especially entrusted to his care."

THE PRESIDENT OF THE BOARD OF TRADE REPLIES.

Sir PHILIP CUNLIFFE-LISTER, in response, said he was very glad they had given him an opportunity of taking some small part in one meeting connected with this most interesting and valuable conference. The members of the Institution were the High Priests of a great and successful industry—an industry which was the architect of its own success. This success was founded upon skilful management, upon constant scientific research, and upon not only the direct production of their main commodity, but on valuable, and increasingly valuable, bye-products. The industry was a model of good relations between employers and employed; and it was also a model in the service which it rendered to the public. He wished really that he had as little difficulty in defending many things as he had on the whole in defending Gas Orders. As he had said, the industry was giving good service to the public; and where the industry prospered, the public, or consumers, came in and shared both in the quality of the article which they received, and in the price at which they received it. This was really a public service; it was really being a public utility undertaking. Lastly, but by no means least, the gas industry was not lacking in what he believed to-day was a matter of the most vital importance, if Britain and British trade and industry were to get the fullest value out of their assets—namely, development. In the face of the increasing output of gas—doubling, trebling, quadrupling decade after decade—anybody would be a fool who said the age of gas had passed. There could be no possible question that there was not only a great need for this industry, but a great future before it. He could promise them that at the Board of Trade they would not be unmindful of the gas industry. But this was really quite an unnecessary undertaking to give to those present, because there were millions of consumers all over the country who were the real safeguards of the interests of the industry which had served them so well in the past. It appeared to him that a great deal of the suspicion that existed to-day—he was not going to make any pronouncement upon Government schemes, for he was not in a position to do that—rested upon a profound misunderstanding of elementary facts. There were many people always prepared to talk a huge amount of nonsense about subjects with which they were largely unacquainted. He had often seen a case damned by being put too high; and from some experience of the gas industry at the offices of the Board of Trade, and some small direct experience of helping to run electricity undertakings in different parts of the world, he said that, whatever politicians of one complexion or another might urge, facts had undoubtedly established that gas and electricity were not necessarily enemies, but that both, worked at the highest efficiency, were vital to any country. He thought those present, who certainly knew more of the gas side than he himself did, would probably bear him out in this: That if they took those parts of the United States where electricity had been most ably developed, they would find gas most ably developed side by side with it; and that the people whose evidence and experience were rightly taken in this country as showing the great strides made by electricity—the very men upon whose evidence and experience this was founded—were the men who had proved in practice that the two had to be developed side by side. So far in the past when Government aid had been given, gas and electricity had been treated on absolutely identical and equal terms; and he was quite sure that any representations which the gas industry might have to make with regard to any proposals that might be put forward, would be considered at their full value, both in Government circles and by the House of Commons. This was only fair play, which they had the fullest right, not only to ask for, but to demand. But they must not spoil their rightful claim by putting it too high. Do not let them, for example, say, if in some industry—whether electricity or anything else—there was some development which was economically sound and in the interests not only of the industry but of the country at large, which was in its character and its essence applicable only to that industry, that it ought not to be put in hand, and if necessary assisted, because an identical scheme could not be prepared by the gas or other industry. If they attempted to make a case of this kind they would be seriously prejudicing the very valuable claims they had on the Government and on the country. He looked forward with great confidence to the future of the gas industry.

SERIOUS TRADE POSITION.

The toast was not only to the gas industry, but to the trade and commerce of the country; and he wished he could take at this moment an equally hopeful view of all the other industries as he did of gas. If they could show the same advance and the same prospects, if they had only to face the same competition, he should be greatly more hopeful of their future than he was that day. The trade position was unquestionably serious; and it was no use blinking facts. It was serious because they were doing too little business—far too little business—for the population they had to support. There was something about the matter, too, that was not seen in any official return, but which every trader was aware of—and that was the diminishing margin upon which a great deal of this business was being done. In many cases it was at an actual loss; and this was serious. There was another thing that was serious—namely, the disparity between this country's imports and exports. The need was to develop new markets; and this meant that they must have more money to invest. The greater the deficit to be made up in the trade balance, the less there was to invest. This was why it was so tremendously important to restore that balance, and to show a more favourable margin at the end of this year than at the end of last year. This led him to refer to one matter that had been mentioned by Mr. Milne Watson. It was vitally important, whenever they were considering the use of any commodity in this country that was made outside this country, that they should count the cost of importing it, and see whether they could not make the article themselves. It was not only that they were giving more employment in this country by using the home article.

TAR OR BITUMEN.

In the particular case Mr. Milne Watson took, they were not only helping the gas industry, but they were helping coal, which was a most distressed industry. It was not only direct employment they were giving; but if they could diminish the imports, they would be increasing the trade balance, and giving themselves more money to invest. Therefore they should think, not once, but twice before giving preference to what had to be paid for by exports over the article which could be purchased at home. "Without expressing an expert judgment in this controversy," proceeded Sir Cunliffe-Lister, "I should like, purely for the sake of information, to know whether those roads of Kent, which were, I understand, the glory of that county, and the expenditure on which was such a good investment, and which have been the precedent for many great extensions and developments throughout our land, at no small outlay of public money—whether those roads did not attain to their perfection by the use of the despised tar, and not bitumen."

Dr. CARPENTER: I have been motoring for twenty years on the Kent roads. When Sir Henry Maybury was the Engineer upon these roads (on which he was one of the first to use tar), they were model roads. There are many who can speak in support of that.

Sir CUNLIFFE-LISTER (continuing) said he did think it was of enormous importance that a decision should not be come to in a case of this kind, where public money was involved, where employment of British industry was involved, without making quite sure that they could not get, by working to specification, an article which was for the purpose about as good as the thing which they would have to pay for twice over. He hoped that this question might be considered upon its merits, and with due regard to national interests; and that they would try to act, all of them—everybody concerned—in the best interests of the trade of the country.

WORK, AND WORK, AND MORE WORK.

To resume the main theme of his argument, he quite agreed that it was vitally important to-day that people should face facts; and he believed that really they wanted to be told the naked truth. He did not think they desired any concealment. They should have the courage to give British people and British industry the true facts. In every industry both parties were prepared to face facts with all the cards on the table. Difficult as the position was to-day, he was optimist enough to believe in the enterprise, initiative, and capacity of the British people—to believe that they could surmount all their obstacles. The Government would help in every way it could; but there were strict limits to what the Government could do. It could work for settlement abroad; but if stability abroad was important, more important still was settlement at home. It was necessary to avoid "stunts" and costly short cuts, and to study markets. "We have," Sir Cunliffe-Lister concluded, "the best raw material in men that any country has got. We have got to-day throughout our universities as good a training as you can find anywhere else for these men. Let us use those assets. Experience we have; credit we have, second to none. Quality, financial ability—tremendous assets for any industry and any country. Let us make the most of them. In a word, it comes back to what Mr. Milne Watson said—the greatest need for all is work, and work, and more work. We want goodwill and confidence, individual enterprise, and initiative, and at the same time everybody playing for the side." [Applause.]

KINDRED INSTITUTIONS.

Dr. CHARLES CARPENTER submitted "Kindred Institutions." He said he remembered fifty years ago his chemistry master and his old friend disabusing him of the idea that there was much honour to be attached to membership of learned societies. He said then that there was only one to which membership could not be obtained either by purchase or by favour. In the

half-century which had since elapsed, many changes had come about; and he thought they owed a great debt of gratitude to the parent society—to the Institution of Civil Engineers—who had so long lived up to that high ideal of membership as the result of examination. In other words, the application of a test to those desirous of passing through its portals. He was sorry, therefore, to find that his dear old friend the President of the Institution of Civil Engineers was not with them, so that some acknowledgment might have been made of the great work at which he had assisted in this direction. He (Dr. Carpenter) thought they might also take the opportunity of expressing their condolence at the lack of respect which the average public, the average press, and he might say the average authorities, gave to the leadership of the Institution of Civil Engineers. He could not think of any other civilized community among whom less regard was paid to the specialized knowledge of professional men than in this country. The fact of the matter, he thought, was that there were far too many amateur opinions being advertised to-day, to which a certain amount of weight and notoriety were being attached. For the President of the Institution of Civil Engineers they had an admirable substitute in their old friend Sir Dugald Clerk, to whom the gas industry owed a great debt of gratitude for the manner in which he had, clearly and fairly, set out the pros and cons of the coal question as applied to the distribution of energy. His only regret was that this work was not more widely known, or that the great store of facts was not more often drawn upon. They had also with them Mr. W. H. Patchell, representing the Institution of Mechanical Engineers. The foundation of the gas industry was mechanical engineering. It was by the knowledge of mechanical engineers that the business of gas making had been developed. It was perfectly true that now they called in more and more the assistance of the chemist in working out those problems the solution of which was so essential to their development; but even then the business was largely a question of mechanical engineering. They therefore owed very much to the Institution of Mechanical Engineers.

Sir DUGALD CLERK (Past-President and honorary member of the Institution of Gas Engineers, and Past-President of the Society of British Gas Industries), on behalf of the Institution of Civil Engineers, and Mr. W. H. PATCHELL (Past-President of the Institution of Mechanical Engineers), acknowledged the toast. The latter remarked that there was one man in the room —Mr. F. W. Goodenough—who had done more than anyone else in this country to make consumers realize that they were getting service.

THE VISITORS.

Mr. SAMUEL TAGG proposed "The Visitors;" remarking that if there was one lesson the war had taught them it was the value of publicity. With the growth of the gas industry, it had come to be realized that it was one of the essential industries of the country. It was dependent on other industries, and it was also dependent on securing the support of the community—support which could only be based on a knowledge of the work it was doing. Therefore they welcomed the presence of visitors with them that day.

Major-General Sir R. H. LUCE, replying, said he was glad to have an opportunity of telling them how much they appreciated Mr. Bell in Derby—not only as a first-rate gas engineer, but as a citizen who took the greatest interest in the town. Certainly they had a most excellent gas service. As a member of the Town Council, too, he put in very good work.

Mr. REGINALD G. CLARRY, who also replied, said he did not really regard himself as a visitor, but more as enjoying a happy re-union with some very old colleagues. His letter-bag told him that there was a great deal of apprehension in the gas industry as to what might take place in the future in the matter of State pampering of the rival industry. It seemed to him that the anxiety was justified; and it was better that anxiety should be manifested now than after legislation had been passed. Reference had been made to low-temperature carbonization. Though this was not at the moment what one might regard as a commercial proposition, yet developments were taking place. He would advise gas engineers to keep closely in touch with all developments of low-temperature carbonization of coal—particularly from the national point of view of the production of oil. Oil could be produced from coal by various processes; and he thought the right place for doing it was at the gas-works. ["Hear, hear."] If at the birth of electricity the gas industry had taken the view that the right place for its production was at the gas-works, the minds of the members would not have been filled with the anxiety that occupied them at the present time. The gas industry had rendered great service, and had a bright future before it; but whatever they did, they must not hide their light under the bushel of public misapprehension. They must let people know what they stood for—that the gas industry was the greatest industry for the conservation of coal—and then he felt sure they would maintain in the future the excellent record that they had set-up in the past.

AT DERBY—THE PRESIDENT'S HEADQUARTERS.

On Friday morning, just before 9 o'clock, the majority of the large contingent of *congressistes* and their wives assembled at St. Pancras for the last social event of the week—the visit to their President's town and its beautiful countryside, and enjoyment of the hospitality of the Chairman and Directors of the Derby Gas Light and Coke Company. The train was a "Wembley Special," and the accommodation thereon and the attendance provided left nothing to be desired. The two-and-a-half-hour journey was soon over, and the visitors found themselves marshalled into waiting tramcars, which conveyed them to the selected one of four destinations—the locomotive works of the L.M. & S. Railway, the carriage and wagon works, the gas offices and Cavendish Street Gas-Works, or the Royal Crown Derby Porcelain Works.

At the locomotive works there was a wealth of interest—the boiler and firebox plating and testing, the forging of link-motion parts, the erecting, and the immaculate painting and many other of the processes which combine to make the modern locomotive the thing of beauty which it is. At the carriage and wagon works it was difficult to imagine that the trade barometer is at its lowest, for they are turning out some 200 wagons a week, and the carriage shops are full. The rough tree sections were passing into the Canadian mill at one end, and the machined and fitted parts of wagons were being delivered in a continual stream at the other end; the sawn planks being subjected to a multiplicity of processes at almost incredible speed—such is the effect of intermediate mechanical handling and workman on piece rates! At the Royal Crown Derby Works the party, mostly ladies, evinced the keenest interest in the skill and precision which produce the world famous porcelain. They were surprised to learn that a piece is at least six weeks in the making, and that it is six times fired for 60 hours, to fix the beautiful colours which characterize it.

As for the works, offices, and showrooms of the Derby Gas Light and Coke Company, we must refer our readers for a description of these to the reprint of the handsome souvenir brochure and illustrations on page 956. In selecting our ticket for the visit, we noticed that it was planned to proceed from the carriage works to the Litchurch Gas-Works; but time did not permit of this, and several of the party were disappointed not to see certain installations—among them the new sulphate plant by the Chemical Engineering and Wilton's

THE PARTY WHICH VISITED THE LOCOMOTIVE WORKS.

Patent Furnace Company. This embodies several novel features, and the Engineer of the station, Mr. Fisher, is entertaining great hopes of its working.

The Luncheon.

The luncheon offered by the Derby Gas Light and Coke Company was served in the Drill Hall, as the Assembly Rooms, which were originally intended for the function, could not accommodate the exceptional number who accepted the invitation. No fewer than 390 sat down to a luncheon which was excellently served.

Mr. William Woolley (Chairman of Directors), with whom was Mrs. Woolley, presided; and with him at the table of honour were: Alderman W. Hart, Lt.-Col. G. A. Strutt, Mr. E. S. Johnson, Mr. M. Attwood (Directors); Mr. and Mrs. J. Ferguson Bell, Mr. C. F. Botley (President-Elect) and Mrs. Botley, Sir Albert and Lady Ball, the Lord Mayor of Manchester (Alderman F. J. West) and Miss West, Sir Henry Fowler, K.B.E. (Deputy Chief Mechanical Engineer, L.M. & S. Railway) and Lady Fowler, Mr. J. H. Follows, C.B.E. (Chief General Superintendent, L.M. & S. Railway) and Mrs. Follows, Mr. Frank Tatlow (late General Manager of the Midland Railway) and Mrs. Tatlow, the Mayor of Halifax, the Mayor and Mayoress of Derby (Mr. and Mrs. Allen Mycroft), Mr. G. Trevelyan Lee (Town Clerk), Dr. Brindley (Medical Officer of Health), Mr. J. W. Horton (County Surveyor), Dr. Laurie,

Mr. Bell Chatting to Mr. J. H. Follows, C.B.E., Chief General Superintendent of the L.M. & S. Railway.

Mr. and Mrs. Thomas Hardie, Mr. and Mrs. W. Doig Gibb, Mr. and Mrs. Madden, Mr. John Peacock, and Mr. W. Moore (President of the Derby Chamber of Commerce).

The Loyal Toast having been duly honoured, Mr. William Woolley rose to say that he had been pressed for a few words, although it had been arranged that there should be no speech-making. He was content to feel that by their very presence their guests thanked the Derby Gas Light and Coke Company for the entertainment. The Directors were exceedingly glad to welcome them, and it had been a real source of pleasure to do so—to know each other better—for they were all interested in one particular industry. He trusted that they had learned something from their visit to Derby Gas-Works, and to the great works of the L.M. & S. Railway, of which Derby was so proud. He felt sure that, when they departed that evening, they would carry with them the same high opinions as they had freely expressed that week in London of the Chief Engineer of the Company.

Chatsworth.

The afternoon drive was to have been to Haddon Hall, but owing to the regrettable fire which recently destroyed the tea-rooms and other parts of the property, the arrangements had to

MR. WILLIAM WOOLLEY.
Chairman of the Derby Gas Light and Coke Company.

be altered; and by the courtesy of the Duke of Devonshire, an intellectual and æsthetic treat was provided in the form of a visit to Chatsworth. The brilliant weather of the week held out, though a storm was threatening and there was a heat mist which impaired the view of this beautiful countryside. Highly qualified guides explained as much about the wonderful treasures of Chatsworth as time would allow; and then the motor coaches took us to Bakewell. Thence the special train journeyed to Derby, and then to London; and thus closed a memorable day.

One thing must not be forgotten—to record the gratitude which was everywhere expressed for the hospitality of the Derby Gas Light and Coke Company and the infinite pains which Mr. Ferguson Bell, his assistants, and staff must have taken in organizing the details of the excursion and looking to the comfort of everybody. In this regard we would specially mention Mr. Harry Clark, the Distribution Superintendent, which brings to mind that the Derby Company have this year provided a President not only for the Institution of Gas Engineers, but for the Midland Junior Gas Association, a fact of which they are duly proud.

MR. H. BULLIVANT, F.C.I.S.
Secretary to the Derby Gas Light and Coke Company.

LEFT TO RIGHT: Mr. C. F. Botley, Miss Bell, the President, Capt. H. M. Haywood (Chief of Police, Derby), Mr. W. E. Price, Mr. E. S. Johnson, Mr. W. T. Dunn.

LEFT TO RIGHT: The Mayor of Derby, the Lord Mayor of Manchester (Alderman Fred. West), Sir Henry Fowler, K.B.E., and the Misses Bell.

A LINK WITH THE PAST.

An interesting letter, including the following statements, has been addressed to the British Empire Gas Exhibit Committee by Mrs. Clara Branson, who before her marriage was Miss Heard:

> I trust you will pardon the liberty I have taken in addressing you; but I have been deeply interested in the reading of the statements made concerning the "Spirit of Coal," gas, in the Palace of Industry at Wembley—shown as a world-wide servant—and the benefits it renders in the home and in business. It plays a great part in providing the necessities, utilities, and luxuries of modern life, and in one-hundred-and-one purposes of domestic use.
>
> You may be interested to know that I am still living—a link with the past—at the age of 81, and am a daughter of Edward Heard, a practical chemist, who did such noble work, which has benefited the public life up to the present moment of time—he being the original discoverer of the purification of gas, which he patented in 1806. He was engaged by a Mr. Winsor, in the year 1804, to deliver lectures in the Lyceum Theatre in London, on "The Application of Coal Gas to the Purposes of Artificial Light." After a series of experiments, he discovered the cause of the offensive odour which (and its irrespirability) rendered coal gas unfit for domestic use; and having proved its efficacy, he took out a patent. This passed the Great Seal in June, 1806, he having been allowed six months to specify, which specification I still have in my possession, with other papers concerning it. It can be seen at any time.
>
> Some years ago my mother received a visit from Mr. Walter King, of Bolt Court, and Mr. Thomas Berridge, Gas Manager at that time at Leamington, who could (were they living) vouch for the truth of what I assert, and kindly placed a stone upon her grave at Kenilworth.
>
> I have given a brief note of a great service rendered to mankind; and although there have been progressive strides in connection with the said discovery, it still lives, and is appreciated in the world as one of the great masterpieces of science.

INSTITUTION BENEVOLENT FUND.

The Annual General Meeting of the Benevolent Fund was held on Wednesday morning, the attendance being very small. Mr. J. FERGUSON BELL was in the chair.

The minutes of the previous meeting were read and confirmed.

The HON. SECRETARY then read the following.

REPORT OF THE COMMITTEE OF MANAGEMENT FOR THE YEAR 1924-1925.

The income for the year ended Dec. 31, 1924, amounted to £534 10s., and was derived from the following sources: Subscriptions, £272 4s.; donations, £89 12s. 8d.; interest on investments, £138 16s. 2d.; interest on deposit account, £3 3s. 10d.; and recovery of income-tax, £30 3s. 4d.

In assistance to widows, orphans, and aged members the sum of £489 18s. was granted. Printing and stationery cost £31 0s. 6d.; postage, receipt stamps, &c., £7 14s. 7d., leaving a credit balance for the year of £5 16s. 11d. (as against a credit balance for the year 1923 of £236 4s. 9d.).

The response to the special appeal issued by the President of the Institution, Mr. J. Ferguson Bell, has resulted as follows:

New annual subscriptions	£10	3	6
Special contributions, or additional to annual subscriptions	47	11	0
Donations (including donation per the Redditch Gas Company of £25) ...	41	5	6
	£99	0	0

The Committee have already, for the year 1925, voted in grants the sum of £517. The corresponding amount for last year was £489 18s The sum voted, of course, is irrespective of any applications which may arise from new cases which may come in.

Indeed, just as this report was being prepared, a fresh application for assistance was received from an aged former member of the Institution, in response to which the Committee are voting the sum of £20.

A copy of the accounts for the year 1924, compared with those for the previous year, duly audited by Mr. S. Y. Shoubridge and Messrs. Wood, Drew, & Co., has already been issued to every member of the Institution.

The two members of the Committee retiring by rotation after the usual three years of service are Mr. Ralph E. Gibson, of Liverpool, and Mr. E. George Hutchinson, of Westgate-on-Sea. To serve in their places the Committee have nominated for election at the annual meeting of the contributors Mr. Ralph Halkett, of Sheffield, and Mr. C. S. Shapley, of Leeds.

The PRESIDENT: You have heard the Report of the Committee for the past year, and I think you will agree that on the whole it is eminently satisfactory. I should like again to express my thanks to those members who were good enough to respond to my appeal, which resulted in an immediate increase in the funds of £99. As I intimated yesterday, the Lord Mayor of Manchester has been good enough to say that he will give a donation of £100, and that is also to the good. This Benevolent Fund does an enormous amount of good work. We received only two or three weeks ago an application from one of our aged members who is in the infirmary and has had an operation; and the result was that we decided to send him at once £10 and a further £10 later on. We could multiply these cases almost innumerably, where the assistance given through the Fund has made all the difference between living reasonably and being on the verge of starvation. The Fund was established so that those who suffer from reverses through no fault of their own, or the dependants of those who are unfortunately taken away, may be assisted. I do not think there is any more beneficial fund of the Institution than this one, and I am extremely glad to know that the members of the Institution are realizing the good work the Fund is doing and that subscriptions are being increased. I would, however, like to emphasize this point. It is not every member who can give large sums, but all can give from 5s. upwards, and I should be extremely glad if every member of the Institution will say "I am going to be a subscriber to the Fund, even if it is only a small amount." The Evening Star Lodge, which generally holds an Emergency Meeting on the Monday evening before our meeting, have in their Charity Box subscribed £14 2s. 6d. I am sure that I am voicing the opinion of the members in saying that we are extremely obliged to them and to the other donors for their great assistance.

Mr. SAMUEL GLOVER: I should like to thank the Chairman for his kindly explanation of the position of the Fund. When the Secretary was reading the Report, he said that a sum of £20 had been given in a recent case, but the Chairman in the course of his remarks showed how this £20 is being given in a somewhat unusual manner. We as members are very glad to know that your kind heart and the kind hearts of those who with you have been looking after this Fund for us, has been warmed towards the work you are able to do in this manner. I know, Mr. Chairman, the very warm place which this Fund has in your heart, and how glad you are that the engineers who are able to do so subscribe to it, and so enable this good work to be carried on for the benefit of those who are in need. I hope that the Fund will continue to prosper. Perhaps I might ask how the £100 from our new honorary member, the Lord Mayor of Manchester, is to be disposed of. You said it was given as a donation, and I should like to know that it will be placed to capital account and will be treated as a source of income for the Fund and not be disposed of in grants. I again thank the Chairman for his very helpful review of the situation, and I have much pleasure in moving that the Report be adopted.

The CHAIRMAN: With reference to the £100 donation from the Lord Mayor of Manchester, at the meeting of the Benevolent Fund Committee this morning it was decided to invest it in War Bonds, so that about £5 a year will come in as income to the Fund.

Mr. WATSON: I should like the privilege of seconding the motion, and I do so with sincere feelings, because I appreciate the help the Committee have given in a case in which I have been interested during the past few months; and I know how much the grant which the Committee have given in that case will be appreciated. This is the second case in which I have been interested, and I do not think I have ever appreciated so much the peculiar necessities under which a past member of the Institution has been placed and has benefited from the Fund. I feel sure that, if such cases were brought in the abstract to the notice of the members of the Institution generally, we should get greater help, perhaps, than we are getting. In this connection I would like to make a suggestion. I do not know whether it will meet with the views of the Council of the Institution of Gas Engineers; but in view of the scanty attendance that we have here this morning, it occurs to me that it might be well worth while holding this meeting in the middle of the proceedings of the Institution itself ["Hear, hear"] about midway in one of the morning meetings, even if the Institution proceedings were suspended for ten minutes or a quarter of an hour. You would then have a very much larger attendance of the members of the Institution, and particularly of those members who are not subscribers to the Fund. I have much pleasure in seconding the motion for the adoption of the Report.

The CHAIRMAN: The report is now open for discussion.

As there are no comments, I will only say that since I entered the room this morning I have received a donation of £1 from Mr. M'Lusky, of Halifax, bringing the result of the Special Appeal up to £100. [Applause.]

The report was adopted.

The CHAIRMAN: We have now to appoint a Trustee in the place of the late Mr. H. E. Jones. The Committee looked round to see who would be the right gentleman to nominate; and there occurred to me the Governor of the Gas Light and Coke Company (Mr. Milne Watson), who is also President of the Gas Council, and, as you know, is very actively associated with all that concerns the gas industry. I approached Mr. Milne Watson, and asked him if he would be good enough to take Mr. Jones' place, and he said that, if it were the wish of the members, he would be very pleased to do so. I brought that before the Benevolent Fund Committee, and they unanimously agreed to ask Mr. Milne Watson to be Trustee. Mr. Dunn communicated that decision to Mr. Milne Watson, and he has written expressing his pleasure in accepting the nomination.

On the proposal of the CHAIRMAN, seconded by Mr. SAMUEL GLOVER, Mr. Milne Watson was unanimously elected a Trustee.

The CHAIRMAN then announced that Mr. Ralph Halkett (Sheffield) and Mr. Charles S. Shapley (Leeds) had been elected by ballot to succeed Messrs. R. E. Gibson (Liverpool) and Mr. E. G. Hutchinson (Westgate-on-Sea), who retire by rotation.

This closed the Benevolent Fund meeting.

EDUCATION SCHEME.

REPORT OF THE ADVISORY COMMITTEE FOR THE YEAR 1924-25.

Adopted by the Committee, May 12, 1925.

The year 1923-24 was fittingly described as a year of foundation laying. That of 1924-25 may be spoken of as one of steady, painstaking building. Brick has been added to brick, and a structure is beginning to take shape. Progress has been slow, but it is hoped all the more sure because of the care taken. Last year it was possible to report only 11 centres at which organized instruction in gas subjects was being given. This year the number has increased to 21 (as per list appended), while there are two other centres at which the earlier parts of approved courses are being taken.

Other applications for the approval of Courses of Instruction are known to be pending, so that it is hoped that the list may be extended in time for the session of 1925-26.

Last year, only 4 centres were in a position to present students for examination. This year 54 candidates are coming up from 8 centres.

The number applying for examination shows a gratifying increase in regard both to external and internal candidates.

The comparative figures are :—

	1923-24.	1924-25.
Internal Students ..	... 36	... 54
External Students ...	... 24	... 56
	60	110

Having regard to the increased number of centres at which courses under the Institution Scheme are now being taken, and to the fact that this will be the last year in which the educational work of the Institution and that of the City and Guilds of London Institute will overlap, it may be anticipated confidently that next year the numbers applying for examination under the Institution Scheme will be considerably increased.

An illuminating side-light on the great need there was for the Institution to take up this work is afforded by the fact that no less than 30 applications to sit for examination had to be refused owing to the students' lack of preliminary scientific training. The fact of these applications being made reveals a desire, on the part of the students, for the advantages the scheme confers, while it is most unlikely that so many would have had to be refused for the present had a satisfactory education scheme been in operation for a longer period.

In considering the applications in question, the Committee has been anxious to deal as sympathetically as possible with every case on its merits, while on the other hand maintaining the high standard which the times and the industry demand. It is satisfactory, therefore, to note that the decisions of the Committee in those cases, unwelcome as they have naturally been, have been loyally accepted, and that the students have seriously set themselves to repair those defects in their fundamental training which have been pointed out to them.

The year has been marked by several outstanding features of interest. It is gratifying to report that both the Ministry of Education for Northern Ireland and the Department of Education for the Irish Free State have accepted the scheme, have appointed representatives to the Central Advisory Committee, and have signified their willingness to co-operate in every way in applying the scheme in their respective areas of administration.

A development of great promise for the smooth working of the scheme is the appointment of Committees of Advice for both Wales and Scotland. These are intended particularly to assist and advise as to his best method of procedure the student who is situated at a distance from educational centres. Moreover, courses of instruction vary so much in the Technical Institutes and Science Schools of the United Kingdom that students are often in considerable doubt as to the best plan of study in their particular circumstances. These local and personal difficulties can undoubtedly best be solved by those familiar with the precise circumstances and conditions which give rise to them; and it is hoped that these Committees of Advice in Wales and Scotland will be appreciated and utilized by many students.

It is with satisfaction we report that a liaison has now been established between the educational work of the Institution and that of our Universities. A graduate possessing an approved degree in Gas Engineering taken in a British University is now exempt from the written portion of the Diploma examinations, but is required to submit a thesis, present himself for oral examination, and satisfy the Advisory Committee as to his professional experience.

Reference has been made to the elimination of the overlapping of the Institution's Education Scheme with the work of the City and Guilds of London Institute. This has been made possible by the thorough revision of the whole of the work of technical education within the industry. As a result of an interview between the Advisory Committee and representatives of the City and Guilds of London Institute, a Committee was set up to consider the whole question. This resulted in—

1. The adoption of a grouped Course for Gas Fitters;
2. The establishment of what have been designated Minor Grouped Courses in (*a*) Gas-Works Practice, and (*b*) Gas Supply Practice, for those unable or not desiring to take the "professional" Courses of the Institution Scheme.

In the establishment and operation of these courses—whereby the Education scheme has been extended so as to provide for all grades of those engaged in the industry—the Advisory Committee and the City and Guilds of London Institute are working in the closest co-operation. Complete syllabuses have been drawn up, and are now embodied with the particulars of the "Major" Courses in the Regulations issued by the Institution, copies of which may be obtained on application to the Secretary, 28, Grosvenor Gardens, Westminster, S.W. 1. The value of the certificates gained in connection with the "Minor" Courses will be considerably increased through their being endorsed by the Institution.

It was with great regret that early in the year the Committee received the resignation, owing to ill-health, of Mr. J. Wesley Whimster as one of the Examiners in Gas Supply. It was at the same time decided to increase the representation of the North on the Board of Examiners by the addition of another member. Mr. George Keillor, of Greenock, and Mr. R. B. Roxburgh, of Newcastle-on-Tyne, were therefore elected to fill the vacant positions.

APPENDIX.

LIST OF SCHOOLS AND COLLEGES GIVING "COURSE" INSTRUCTION UNDER THE SCHEME OF THE INSTITUTION OF GAS ENGINEERS.

Bath Municipal Technical College.
Barnsley Technical School.
Birmingham Municipal Technical School.
Coventry Technical Institute } For early years of Course only.
Wolverhampton Technical College }
Blackburn Municipal Technical College.
Bournemouth Municipal College.
Bradford Technical College.
Bristol: Merchant Venturers Technical College.
Burnley Municipal College.
Coventry (see Birmingham).
Derby Municipal Technical College.
Dewsbury Technical College.
Glasgow Royal Technical College.
Halifax Municipal Technical College.
Huddersfield Technical College.
Leeds Central Technical School.
London: Regent Street Polytechnic.
Westminster Technical Institute.
Manchester Municipal College of Technology.
Plymouth Municipal Technical School.
Portsmouth Technical College.
Salford Royal Technical College.
Stoke-on-Trent Central School of Science and Technology.
Wolverhampton (see Birmingham).

The PRESIDENT: I have the very greatest pleasure in asking our good friend Mr. Goodenough to present the Report of the Education Committee.

Mr. F. W. GOODENOUGH: In presenting on their behalf the Education Committee's report for the past year, I should like to call the attention of members to one or two points. First let me say that, while the Committee are glad to see the in-

crease in students presenting themselves for examination—namely, from 60 last year to 110 this year—they regard the latter figure as very far below the number they hope to see taking the examinations in years to come. One student for examination to 8 statutory gas undertakings in the kingdom—one to 14 of all the gas undertakings of the country—is a very low figure. It is certain to increase as the arrangements made for courses in Gas Engineering and Supply at the various centres get into full working order; and members will have observed with satisfaction the considerable increase in the number of centres at which such courses have been arranged. But something more than the establishment of courses at numerous centres is necessary before we can hope to get the number of young men there ought to be, throughout the country, qualifying themselves for promotion and fitting themselves for raising the standard of knowledge and efficiency in the industry. Gas undertakings everywhere should, definitely and practically, support the scheme of the Institution, adopt it as part of their own plans for building up staff, make it well known to everyone in their employment, and not only encourage, but assist, would-be students to take-up courses, both by liberal treatment in regard to travelling expenses and to time-off for attending the necessary classes, and by adequate recognition of success in the examinations. The industry needs, and as competition becomes more and more keen will more and more need, well-educated staffs—not only technicians and scientists in the works and laboratories, but also representatives with both technical knowledge and commercial capacity on the districts. Gas undertakings must create the demand for better human material by paying qualified men good salaries and by being prepared to pay still better salaries as men become better qualified. The machinery for assisting men to improve their qualifications now exists, and is being steadily improved as experience proves necessary—for we do not regard the scheme as stereotyped, but as open to amendment always. We believe the men exist who are anxious to qualify for advancement. It is for the industry to make it clear that better qualified men are wanted, and will be paid for according to value.

On this point of the men being willing or unwilling to work earnestly for their better qualification if they are encouraged to do so, I should like, if I may in passing, to enter a protest here against the sweeping attack on the present generation of young men made by Dr. Arthur Shadwell in "The Times" last Wednesday. Writing with that air of omniscience and authority so often assumed by the literary onlooker (who by no means always sees most of the game of business, because he has never played it, and knows little of those who do), Dr. Shadwell roundly states that "there is really something wrong with the present generation; they neither work well nor play well. They seem altogether lacking in energy and serious purpose. . . . And this holds good," he adds, "of all classes; they are all crazy for amusement and show."

Well, I am sure you will agree with me that it simply is not true that our young men neither work well nor play well. Of course they are not all paragons of virtue and diligence; but when we have large numbers of men working for us who are ready and willing to give up three at least and often more evenings a week to attend science and other classes, and travel considerable distances to do so, and many more are constantly putting in long hours on their companies' work without a murmur—keen on their business and on their studies, as well as keen on their sports—it makes one resent warmly such superficial criticism as that I have quoted.

And we in more responsible positions are regarded as decadents unworthy of our forebears, because we play golf on Saturday mornings—sometimes—or go away for the week-end on Friday nights. If some of our arm-chair critics could realize how the labour-saving machinery of modern business life has increased the hourly output of nervous energy by those in administrative positions, they would hold their tongues, or talk sense. Very few people probably realize the extent to which the telegraph, the telephone, the shorthand-typist, the dictaphone, the motor car, have combined to make it possible for a manager to-day to do actually three times as much work in an hour as could his most diligent grandfather, and how in so doing he uses up so much nervous energy as to make it imperative that he should have longer time for re-creation (using the word in its truest sense) than was necessary for the manager working at the lower pressure of former days.

This digression is, I suggest, not altogether irrelevant to my task of presenting our report on Education. If the present and future generations are both to work well and to play well, as we believe they wish and are prepared to do, and to carry this great industry through present contests to future victories, and to increase its power of serving the nation with satisfaction and profit, they must be given every encouragement to get themselves well educated under conditions that do not put upon them too great a nervous strain. We of the Committee are therefore anxious to arouse fully the interest, and enlist fully the help, of every member of the Institution in the steps that are being taken to make it possible for every man to get the education he needs.

This brings me to two other points we desire to stress. The first is that, to make the Institution scheme meet the needs of as large a number as possible of the men in the industry who feel the desire for further education, we have organized, and added to the scheme, what are called the "minor grouped courses" in Gas-Works Practice and Gas Supply Practice. These are designed mainly to fit the needs of those (and there are many) in the industry who do not aspire, or who are not able, either to become professional men of such knowledge and experience as would enable them to obtain Higher Certificates or Diplomas in Gas Engineering or Supply, or craftsmen as highly qualified as those able to pass the practical examinations in gas fitting, yet are keen to demonstrate that they possess a good general knowledge of the practical operations of the industry in which they are employed, and are thereby better qualified to perform the duties on which they are engaged, whatever those duties may be. We believe that by thus providing for three general categories of students—who may be classified as (*a*) professional men, (*b*) craftsmen, and (*c*) those who are neither the one nor the other, but should understand the operations of both—the scheme has been considerably improved; that it will draw to itself an increased number of students; and that it will secure the active interest and support of an increased number of the boards and committees, as well as managers, of gas-works throughout the country.

The other point we wish to emphasize is that we have done, and will do, everything we possibly can to make the scheme available for every man in the industry who desires to take advantage of it; but that our desire so to do must always be governed and limited by the paramount need of maintaining such a standard of study and instruction required from every student as shall ensure that the possession of certificates and diplomas granted by the Institution and endorsed by the Board of Education shall testify beyond doubt that the holders have reached definite standards of knowledge, training, and experience. Employer and employed alike must be able to feel confident that a certificate or diploma means, and is known to mean, something definite and practical in relation to the holder; or the scheme will fail of its prime object. So clear are the Committee on that point, so certain are they that, in maintaining—and, in the course of time, raising—the standard of value of the certificates and diplomas, they have the full support and mandate of the members of the Institution, that they are obliged to have that consideration always in mind in adjudicating upon the qualifications of students to sit for examination. Especially in these early days of the working of the scheme, the Committee are anxious to err, if they err at all, in favour of the would-be candidate; and they have accepted some on the border line who in later years they would certainly reject. This is what they desire that all members should know; and they desire to say that no one more regrets the refusal of admission to examination of a student than they do. The value of the certificate, however, now and in the future, must always be the prime consideration.

Those who represent the Institution on the Committee desire to put on record their great appreciation of the assistance rendered to them so readily and generously at all times by the members representing the Education Authorities. Those representatives could not be more devoted to the service of the scheme if they were actually engaged in the industry; and their knowledge and experience are invaluable. Finally, let me say that all members of the Committee appreciate, as I am sure all members of the Institution appreciate, the work done by the Board of Examiners, whose task is neither easy nor light, and who perform it in a spirit beyond praise—words equally true of our Organizing Secretary, Mr. Walter Hole, who lives for the scheme and for those it is designed to assist, and who spares neither time nor energy in its service.

I beg to move the adoption of the report.

Mr. Samuel Tagg: I have very great pleasure in seconding the adoption of the report. I need say nothing more than endorse the appeal which the Chairman of the Committee has made for the support and co-operation of the engineers and undertakings throughout the country to make for the proper utilization of the scheme which has been prepared and which has been designed, as far as possible, to meet every conceivable condition which obtains in different parts of the country. I should also like to endorse his reference to the invaluable work of the members of the Education Authorities on the Committee. I think there is no Committee of the Institution which has done more work than the Education Committee.

The President: The report is now open for discussion. I am sure we of the Institution feel very much indebted to the Education Committee—and especially the Chairman—for the great amount of work which they have put into this scheme. It is for the members of the Institution to show their appreciation of the work which has been done; and you can best do this by getting those connected with your undertakings to take advantage of the scheme. It is absolutely necessary, if we, as an industry, are to maintain our position, to have men trained technically; and this scheme has been thought out, as I mentioned in my Address, with this object in view. It is receiving the support of the various Education Authorities, and I do hope that members will support the scheme as it really deserves. The opening remarks of the Chairman of the Committee, Mr. Goodenough, have so completely covered the ground that it seems there are no questions to be asked.

The report was adopted.

THIRTEENTH REPORT OF THE RESEARCH SUB-COMMITTEE OF THE GAS INVESTIGATION COMMITTEE OF THE INSTITUTION OF GAS ENGINEERS.

I. AERATION OF LIGHTING BURNERS. II. DETERMINATION OF SPECIFIC GRAVITY OF GASES.

Adopted by the Gas Investigation Committee, May 21, 1925.

RESEARCH SUB-COMMITTEE.

Chairman: Emeritus Professor Arthur Smithells, C.M.G., D.Sc., F.R.S., Director of the Salter's Institute.

Representatives of the University of Leeds: Professor J. W. Cobb, C.B.E., B.Sc., F.I.C. (Honorary Secretary), Emeritus Professor J. B. Cohen, Ph.D., D.Sc., F.R.S., Mr. G. R. Thompson, B.Sc. (One vacancy.)

Representatives of the Institution of Gas Engineers: Messrs. J. Bond, O.B.E., T. Glover, C.B.E., M.Inst.C.E., H. Pooley, M.Inst.C.E., S. Tagg, M.Inst.C.E., and C. Wood, O.B.E. Mr. C. S. Shapley was co-opted a member of the Research Sub-Committee for the purpose and period of research work at the Leeds Gas-Works.

Research Chemists: James W. Wood, M.Sc. (Tech.), A.I.C., A. Parker, D.Sc. (Birmingham), M.Sc. (Manc.), F.I.C.

Research Assistants: H. Kerr, A.I.C., Diploma Fuel and Metallurgy (Leeds), G. B. Howarth, M.Sc., Gas Engineering (Leeds), A.I.C., and A. C. Monkhouse, Ph.D. (Leeds), B.Sc., A.I.C.

INTRODUCTION.

The constitution of the Gas Heating, Lighting, and Ventilation Research Committee has not changed during the year, and it has continued to act under the Chairmanship of Professor Smithells as the Gas Research Sub-Committee of the larger Gas Investigation Committee.

Work has been continued under the supervision of Professor Cobb in two main branches for which Mr. J. W. Wood and Dr. A. Parker have been immediately responsible. All the work this year has been carried out at Leeds, partly in a laboratory provided by the Leeds Gas Department at the Meadow Lane Gas-Works, and partly on the new Corbet Woodall Experimental Gas Plant now attached to the Department of Coal Gas and Fuel Industries at the University.

The principal work to which Mr. Wood, assisted by Mr. G. B. Howarth, has given up his time has been a continuation and development of those studies in the aeration of burners by injection which have already formed the subject matter of the 9th and 11th Reports. It may be recalled that after a certain amount of general preliminary experimental investigation had been carried out, some typical heating burners of the types used in ring burners and gas fires were examined, their behaviour under deliberately varied conditions of operation being studied and summarized. Then came the turn of the lighting burners, upright and inverted, and the careful investigation made of these during the past twelve months forms the subject matter of the 13th Report (Part I.). The methods of testing had to be modified because of the comparative compactness and delicacy of construction of the lighting burner, and the necessity for making all measurements with the very minimum of interference with the delicately balanced streams of gas which had to be examined.

A number of interesting points emerged which can be found in the report. We have again adhered to the plan of placing in the forefront of each report a special introduction explanatory of what was projected and a summary of the principal results obtained.

An interesting deduction made from a large number of observations was that the degree of aeration by primary air obtained in an ordinary lighting burner, working normally and satisfactorily, was less than half that necessary for complete combustion. This indicates the high order of importance attaching to the construction of those parts of the burner and its accessories which influence the supply of secondary air, which must be made effective if good illumination is to result.

One of the factors of primary importance in aeration is the specific gravity of the gas which determines its injecting power, and it has been plain for some time that for the better information and equipment of the gas industry it was advisable to place the experimental determination of specific gravity on a better footing. Some careful work has been carried out in this connection, and it has been shown that, if properly installed and used, apparatus described by Blackie (Fuel Research Board Report, No. 5) can be operated with great accuracy and reasonable celerity. The necessary precautions and corrections are indicated (13th Report, Part II.).

Notes have been prepared too by Mr. Wood and Mr. Howarth embodying the experience of the Research Staff during the last seven years, on some important points in accurate gas analysis, and these have been put forward in an appendix.

Dr. Parker and his assistants have been occupied in getting the Corbet Woodall Experimental Gas Plant into a proper condition for the carrying out of reliable experimental work by its use, and in the making of preliminary tests. This has necessitated careful study of detail and some modification of the plant. A description of what has been done is published in the 14th Report to serve as a record in the Transactions of the Institution of Gas Engineers of the form taken by this important addition to the equipment of the University of Leeds.

The Committee would like to acknowledge its indebtedness again to Mr. J. W. Wood and Dr. A. Parker, the Research Chemists in charge of the two branches of its work now reported upon, for the continuing zeal, ability, and initiative which they have brought to bear upon the work committed to them, with the valuable aid rendered by Mr. Howarth as assistant to Mr. Wood, and by Mr. Kerr and Dr. Monkhouse as assistants to Dr. Parker. The opportunity is also taken of thanking Mr. C. S. Shapley and the Leeds Corporation Gas Department for the greatly appreciated facilities which they have continued to provide at the Meadow Lane Gas-Works.

SUMMARY.

PART I.

1.—This report (Part I.) is concerned with the degree of aeration of a number of typical low-pressure upright and inverted lighting burners, suitable for domestic use and for street lighting.

2.—The tests have been conducted under a variety of conditions at pressures up to 4 in. water-gauge (w.g.), mainly with gases of sp. gr. 0·49 and calorific value 460-470 B.Th.U. gross per c.ft., the nitrogen content being 10 to 11 p.ct. The average total theoretical air requirement per c.ft. of gas for complete combustion was 3·9 c.ft.

3.—The curves obtained, connecting air-gas ratio and gas pressure, were all of the same general type, showing a rapid increase in aeration with pressure up to 2·5 in. w.g., above which the further increase in aeration was relatively small.

4.—The amount of air injected as primary air, when the burners were adjusted as in normal practice, was usually slightly less than half the total air required for complete combustion.

In most cases, with a pressure of 2 in. w.g. or above, this limit was imposed by the necessity of obtaining *with the gas, mantle, and burner in use,* a stable flame of suitable size and shape for yielding reasonable illumination, and not by inability of the burner to inject a greater quantity of air.

5.—The quantity of air injected in the inverted burners tested, when adjusted for best illumination with

gas of the above quality was 1·7 to 2·1 c.ft. of air per c.ft. of gas, at a pressure of 2·5 in. w.g., although some of the burners were capable of injecting up to 2·5 c.ft. of air per c.ft. of gas when the air ports were fully open. The corresponding figures were higher for the upright burner.

6.—The air-port area provided when the shutter was fully open was in no case so small as to account for a low air-gas ratio; and the degree of aeration was not proportional, even in the roughest sense, to the air-port area, after a certain size, dependent upon the design of the burner, had been exceeded.

7.—In lighting burners (as with gas rings and gas fires—9th and 11th Reports) the heating-up of the appliance when in use materially reduced the quantity of air injected as compared with the performance on first lighting-up, when the burner, gas, and air were all at room temperature. This effect was much more pronounced with lighting burners than with gas rings and gas fires, amounting at times to as much as a 40 p.ct. reduction.

8.—With an upright incandescent burner the use of a chimney exerted no appreciable effect upon the primary aeration of the burner; the improvement in aeration obtained by the use of such a chimney being apparently due to more effective secondary aeration.

9.—The discharge-pressure relations for a number of typical commercial burner nipples have been determined. They exhibit considerable variations among themselves, and over the range ¼ to 4 in. w.g. deviate appreciably from the generally assumed relationship that the discharge is proportional to the square root of the pressure. For the same gas and nipple, however, and for a range of (say) 1 in. w.g. above and below a working pressure for which the discharge has been determined (say, 2·5 in. w.g.), the error resulting from the application of the usual formula would in general be less than 1 p.ct.

PART II.

10.—Much attention has been paid to the determination of the specific gravity of gases. The differential column method described in Technical Paper No. 5 of H.M. Fuel Research Board has been carefully examined. Full details are given of the instruments and the methods we have adopted, and our results show that the method is convenient, rapid, and capable of yielding results correct within ± 0·002 with ordinary town gas (sp. gr. about 0·5).

11.—A critical review is included of the methods of gas analysis adopted in the course of our investigations.

PART I.

AERATION OF LIGHTING BURNERS.

Introduction.

This report is the natural continuation of the 9th and 11th Reports of the Gas Investigation Committee, dealing with the factors which influence the amount of air injected by gas burners. It extends the investigation to cover lighting burners, both upright and inverted, of types suitable for domestic and for public lighting.

In selecting the burners to be tested, care was taken that they should be good specimens of their class, each burner representing as far as possible a commonly occurring type, with some characteristic feature either in construction or mode of operation. Careful inquiry seemed to indicate that, but for one well-known exception, the use of a fixed orifice in lighting burner nipples was declining; and most of the experimental work in the present report was conducted with variable nipples of the needle-regulated type, shown in cross-section in fig. 6. As to the relative injecting efficiencies of single fixed orifices, multiple fixed orifices, and variable nipples, we are not yet in a position to speak; but of the adaptability of the latter for use with different grades of gas, and supplies at a variety of pressures, there can be no question. The results of an examination of a number of these nipples, in an attempt to obtain some discharge characteristics, are given later in the report.

So far as reporting the results of tests is concerned, these variable nipples present a serious problem, for there is great difficulty in conveying to a reader an idea of the precise adjustment of a commercial nipple, and even the experimenter himself may have difficulty in defining or reproducing a particular adjustment, while calculations of velocities of flow, &c., of the gas stream from the nipple become almost impossible.

Unless otherwise stated, the nipples have been adjusted as follows. Upon the basis of the results given in the 1st, 2nd, and 3rd Reports of the Gas Investigation Committee, there was selected for each burner a certain thermal rate which might be expected to yield a reasonable illuminating power and thermal efficiency. Knowing the calorific value of the gas, it was a simple matter to deduce the corresponding gas rate; and it was further agreed that the nipple should be adjusted to deliver this quantity with a pressure of 2·5 in. w.g. immediately behind the regulating needle. A margin of ± 5 p.ct. was allowed on this initial adjustment, because slight changes in gas quality, specific gravity, temperature, and barometric pressure would have rendered adjustment to a precise rate most difficult, and it is doubtful whether any particular advantage would have been obtained thereby. The nipple thus adjusted was then used for a series of aeration tests at different pressures without being further disturbed—*i.e.*, for the time being it became a "fixed orifice" of a particular design. This group of tests indicated to what extent further adjustment might be necessary to secure satisfactory behaviour of the burner.

In nearly every case the degree of aeration was determined in the first place with the gas unlighted. This enables one at the outset to pick out burners presenting a high resistance to the flow of gas and air, and provides a basis for estimating the relative importance of thermal and injector effects in determining the final aeration of the burner.

The tests have all been conducted with gases of a specific gravity not far removed from 0·5, and as a matter of convenience a works supply was used having a specific gravity ranging from 0·477 to 0·500. The gas for any particular series of tests was stored in a 200 c.ft. experimental holder, and drawn upon as required. The complete series of tests with any one burner usually extended over several days, and it was found impossible to keep the specific gravity of the gas constant for the whole series, even when working upon gas from one filling of the holder. There was a progressive lowering of the specific gravity of the gas when standing in the holder, which was indicated quite plainly by the differential column apparatus, and was consistent with the removal of CO_2 from the gas as shown by analysis of the portions used in tests on successive days. For gas of sp. gr. 0·5 a removal of 1 p.ct. of CO_2 would reduce the sp. gr. by 0·010—*i.e.*, by 2 p.ct.

The analyses given in Table 1 indicate the general character of the gases used, and where the specific gravity calculated from the analysis differs from that quoted in connection with any particular series of tests, the difference may be ascribed to the changes taking place in the holder between the times of making the aeration tests and gas analyses respectively. It was in this connection that the development of a rapid and reasonably accurate method of determining specific gravity was of the greatest service (see Part II).

The gases were all produced by steaming in vertical retorts, a certain amount of water gas also being added, and it will be noted that the nitrogen content is low, 10 to 11 p.ct. The average amount of air theoretically necessary for the complete combustion of 1 c.ft. of the gases used was 3·89 c.ft. and there was very little variation in the different samples. Due allowance was made for the small amount of oxygen already present in calculating this air requirement, which is the amount actually to be supplied either as primary or secondary air.

The air-gas ratios were determined in the manner already described for other burners—*i.e.*, samples were drawn from the burner at a point where mixing of gas and air might be assumed to be reasonably complete, and the CO_2 produced per c.ft. of the mixture when burned

over copper oxide was determined. This was compared with the CO_2 produced upon combustion in the same way of the gas in use. A small correction for CO_2 present in the air of the room was applied. All analyses were made in duplicate.

Lighting burners are comparatively small appliances and extremely sensitive to changes in the degree of aeration. Special care was therefore necessary to see that the sampling device and method of sampling, while securing a representative sample of the mixture, interfered as little as possible with the normal action of the burner. This necessitated a very small sampling tube, and the samples were drawn into a mercury sampler of 120 c.c. capacity through a steel tube of only 1 mm. external diameter ($\frac{1}{2}$ mm. bore), and from 4 to 6 min. were required for collecting a sample. Provision was made for maintaining a slow stream of the mixture to be sampled through a branch arm by a regulated "pull" from a water pump; but even had this not been done, the dead-space in the connecting tube (only 15 in. long) would have had little effect upon the aeration value. The steel tube was silver-soldered into a small brass bush which could be screwed into an appropriate place in each burner. The sampling points are indicated by arrows in figs. 1 to 9. In all cases the lighted burner was allowed to run for at least an hour before commencing aeration tests, and for about half-an-hour after any readjustment of gas rate, so that fair equilibrium should be attained in the thermal condition of the burner.

The tests with the various burners are not reported in the order in which they were made, and it will be noted that in a number of cases subsidiary experiments have been conducted to elucidate points of interest. As in previous reports, observed gas rates are given which have not been reduced to the usual standard temperature and pressure. In the case of unlighted burners, the gas and air would be at the same temperatures within 1° or 2° Fahr., and volumetric air-gas ratios would be unaltered on reduction to standard conditions. In the case of lighted burners it will be seen that the gas rate for a given pressure is often appreciably affected by heating-up of the nipple by conduction or radiation. There is great uncertainty as to the temperature of the air injected when it reaches the air ports with the lighted burners. Ordinary thermometers cannot be used for determination of its temperature, because any attempt to screen them from the effects of radiation would inevitably prevent the free access of air to the air ports of the burner. In the later types of inverted burners the incoming air is considerably heated. From the method of determination, the air-gas ratios calculated are the equivalent ratios on the basis of gas and air at the same temperature, whatever the actual temperature of either may have been during the test.

The tests were conducted at pressures within a few hundredths of an inch, $\frac{1}{2}$ in., 1 in., 2 in., and 4 in. w.g. for each series. On figs. 1, 4, and 7 two pipes are shown. The one nearer the burner is that to which the pressure gauge is attached, the pressure being determined with the burner in operation. The other is for the gas supply. The aeration results were carefully plotted for each pressure, and the values given in the tables were read off from the original curves to correspond exactly with the pressure quoted. Facilities were not available for combining accurate photometric determinations with the aeration measurements. In most cases where changes in illuminating power are reported, they were of such a character as to be unmistakable, while in others use was made of approximate determinations with the Lumeter.

UPRIGHT INCANDESCENT BURNER (No. 1).

The upright burner chosen for test was a recent pattern by a well-known maker (fig. 1). It was extremely simple in construction, and the body could hardly be made shorter than in this model (overall length of burner and nipple $3\frac{7}{8}$ in.). The principal resistance in the burner was undoubtedly the head of pierced refractory material, in which the total area for passage of gas was about two-thirds that of the minimum cross-section of the mixing tube. The burner was very similar to the simple burner designated "No. 1" in the 1st and 2nd Reports of the Gas Investigation Committee, or that described as "No. 3" in the Uddingston tests of the 2nd Report. It differed from both, however, in so far that a variable needle-regulated nipple replaced the fixed nipples of the earlier burners. The air ports consisted of slots in two concentric movable cylinders. The maximum air-port area with 8 slots fully open was ·50 sq. in., which was 3·4 times the throat area of the mixing tube. The sampling tube in this burner was screwed into the side-wall of the expansion immediately below the burner head, where it could not obstruct the free travel of the air-gas mixture.

(1) Only $\frac{1}{2}$ in. of mantle giving useful illumination.
(2) About $\frac{3}{4}$ in. " " " " "
(3) About half the mantle passably well heated. Much better general effect by closing all but one air slot.
(4) Mantle fully heated and burner slightly noisy. Slightly better result with only two air holes open.
(5) As with chimney, but partial closing of air holes renders results slightly inferior.

Minimum cross-section of mixing tube = 0·150 sq. in.

Fig. 1.—For aeration curves see Fig. 12.

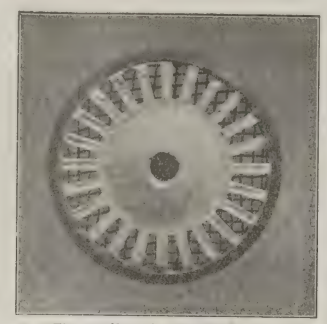

Fig. 2.—Head for upright burner.

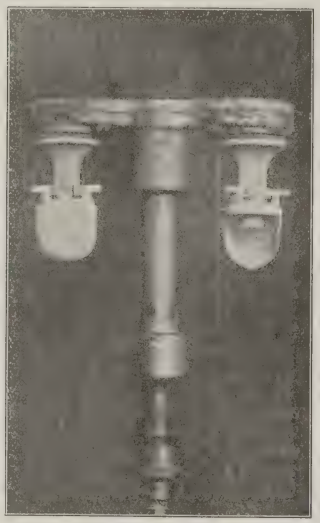

Fig. 3.—For aeration curves see Fig. 13.

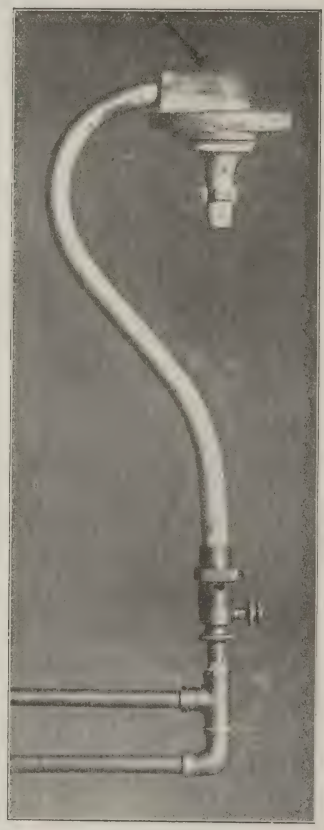

Fig. 4.—For aeration curve see Fig. 15.

The aeration curves for this burner were of a type which has become quite familiar, showing a rapid increase in aeration with pressure up to about 2 in. w.g., after which the further increase in aeration with pressure was relatively small (fig. 12). The degree of aeration reached with the unlighted burner was the highest attained in the experiments recorded in this report—viz., 4·41 c.ft. of air per c.ft. of gas, thus exceeding the amount of air theoretically necessary for complete combustion of the gas by 14 p.ct. Had the gas been one of 500 or 525 B.Th.U. gross per c.ft., however, and of the same specific gravity, exactly the same air-gas ratio would have been attained, but this same amount would then have represented a quantity somewhat short of that theoretically necessary for complete combustion. The aeration curve obtained for the lighted burner when fitted with the usual cylindrical glass chimney (6 in. high) was practically of the same shape throughout as for the unlighted burner, but the aeration had fallen to only 58 p.ct. of its former value; the highest air-gas ratio recorded being 2·56 c.ft. of air per c.ft. of gas at 4 in. w.g. pressure. Under these conditions, when burning gas of the quality indicated, at a rate of slightly over 6 c.ft. per hour, the mantle (usual "C" size) was fairly uniformly heated throughout, and the burner was just on the point of making the purring noise usually associated with full or over-aeration. While this degree of aeration may rightly be regarded as "over-aeration" for the purposes of combustion of this particular grade of gas in such a burner, it represents only two-thirds of the amount of air necessary for the combustion of the gas, and the remainder must be supplied as secondary air. As a matter of fact, the noise was eliminated and the illuminating power of the burner was appreciably increased by closing all but two of the eight air slots at this pressure, thereby reducing the primary aeration. (N.B.—This is by no means a reduction of the primary air to 25 p.ct. of its former value. See later). It would seem from observation of this burner that gas of the quality in question, when supplied with some 60 p.ct. of its theoretical air requirement as primary air, burns with a flame which is rather too conical to yield the best results with the usual type of cylindro-conical upright mantle, and it is necessary, especially at the lower gas rates, to enlarge the flame

Fig. 5.—Front view showing both mantles.

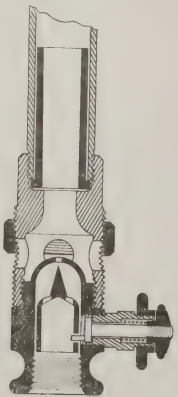

Fig. 6.—Detail of nipple, about full size.

by cutting down the primary air. A larger area of the mantle will then be heated, but the vigour of the combustion will be reduced. It is not possible to say, without resort to experiment, what part must be played by intensity, and what by illuminated area of mantle to secure the most efficient result in any particular case. It is certain, however, that regulation of the primary air gives us a means of controlling flame size and shape in the case of the upright mantle burner, and that so long as it is desired to obtain the maximum efficiency from the existing type of mantle and burner, this must be done by restricting the primary air to a quantity considerably short of that theoretically necessary for complete combustion of the gas. In these experiments, the highest degree of aeration, although considerably short of theoretically complete aeration, has definitely not yielded the highest efficiency and illuminating power. The third group of experiments in Table 2 was made with the chimney removed. (Points marked "x," fig. 12). In the 2nd Report of the Gas Investigation Committee, pages 291-293, it was pointed out that many upright burners were used in this state, and that the illuminating power was in consequence frequently lower than it might otherwise be. The beneficial effect of the chimney must be due almost entirely to the control which it exercises upon the secondary air supply and to conservation of heat in the neighbourhood of the mantle, for the above experiments indicated a practically negligible difference in the primary aeration figures whether the chimney was present or absent. The greatest difference was at 1 in. pressure, and this was due in part to the reduced gas rate consequent upon heating-up of the gas nipple because of a reduction in the cooling stream of air which the chimney develops around the burner body.

STREET LIGHTING BURNER (No. 2).

The burner chosen for test was one in extensive use for street lighting by the Manchester Corporation Gas Department, and was kindly supplied by the Superintendent of Street Lighting (fig. 3). It was provided with a single fixed orifice for gas delivery, the gas nipple being mounted above a small floating-plate governor which cut down the pressure at the nipple to about 2½ in. w.g. As it was desirable, for the purposes of our experiments, to test up to 4 in. pressure, the governor was removed. The stem of the burner was a plain parallel tube 5¼ in. long by ½ in. bore, provided with two five-sixteenth in. diameter holes for air intakes. The maximum air-port area was thus 0·78 times the cross-section of the mixing tube. The burner was fitted with a cast-iron superheater head carrying two Sugg fireclay nozzles for No. 2 (medium) mantles. In carrying out some of the tests with the unlighted burner, a sheet of tin 12 in. in diameter was mounted on the stem of the burner three-quarters of an inch above the air intakes, to prevent contamination of the air supply with gas discharged from the nozzles. With the lighted burner this precaution was unnecessary, as the draught generated by the burner carried the products of combustion away from the air ports.

The aeration-pressure curve for the unlighted burner was very similar to that for the upright burner, although the air-gas ratios are all much smaller (about three-quarters of the value for the upright burner), and the change in direction of the curve below 1 in. pressure was rather more pronounced.

4·00	6·57	1·82	100	48

Some additional tests were made to ascertain, if possible, the cause of these small air-gas ratios. Tests were made at 4 in. pressure (gas unlighted) with and without the mantles on the nozzles. The air-gas ratios did not differ by more than 1 p.ct. from one another or from those already obtained. The closely fitting mantles therefore were not the cause.

There was in the upper part of each nozzle a wire-gauze grid, about ⅝ in. dia. The area occupied by wires (20 per lineal inch, 28 S.W.G.) was approximately equal to that of the spaces between them—i.e., 0·152 sq. in. —which was nevertheless still twice that of the final outlet area at the tip of each nozzle—viz., 0·0767 sq. in. Comparative tests were made at 4 in. pressure with and without these gauzes in position. The air-gas ratio without the gauze was definitely the higher, but only to the extent of 2 to 3 p.ct. This, it should be pointed out, was for a new gauze. In practice these mixing and dis-

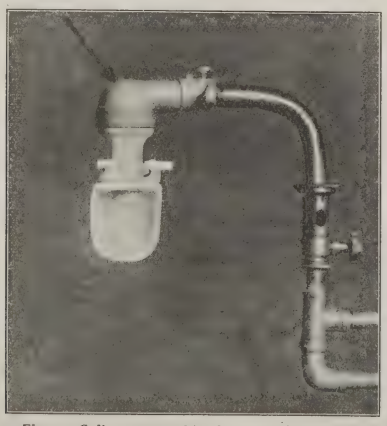

Fig. 7.—Gallery removed to show superheater and nozzle.

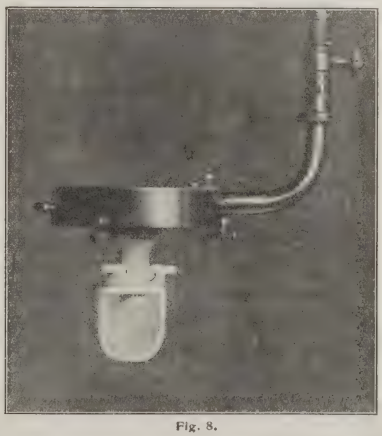

Fig. 8.

For aeration curves see Fig. 16.

tributing gauzes act as filters, and, particularly in domestic use, become corroded and covered with partially carbonized dust of a fluffy character, which may seriously restrict the area for the flow of the air-gas mixture, and consequently reduce the degree of aeration.

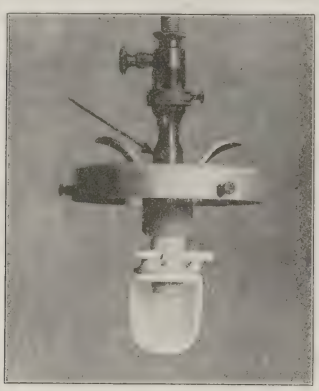

Fig. 9.—For aeration curves see Fig. 117.

The question naturally arose as to whether the air ports were of adequate size or not. The most convincing answer would have been given by repeating the tests with enlarged air ports. This was not practicable; but comparative tests were made at 1 in. and 4 in. pressure with the air ports fully open, and again, when only half open. The results indicated a reduction of the air-gas ratio to 83·5 p.ct. of the fully open value at 4 in. pressure, and to 79 p.ct. at 1 in. pressure. The mean reduction in aeration on half-closing the air ports of this burner was thus only about 20 p.ct., and it is reasonable to assume, therefore, that any practicable enlargement of the openings beyond their present "fully open" dimensions would have relatively little effect upon the air-gas ratio. In passing, it is of interest to note that the reduction in aeration was not a strictly constant proportion over the range of gas pressures used, and that a reduction of the air-port area to one-half affected the degree of aeration in a more marked manner than halving the effective area at the base of the nozzles by the insertion of wire gauze.

Fig. 10.

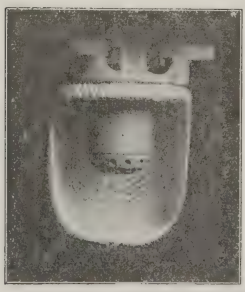

Fig. 11.

Enlarged views of alternative nozzles for above burner.

The tests with the lighted burner yielded an aeration curve of the same general type, with, however, a much lower degree of aeration. It approximated to 56 p.ct. of the corresponding values for the unlighted burner, and at its very best (4 in. pressure) was only 1·82 c.ft. of air per c.ft. of gas, or 48 p.ct. of the theoretical air requirement for this grade of gas. At 1 in. pressure, about one-third of the mantle was heated, while at 2 in. seven-eighths of the mantle was heated, and illumination might be considered just satisfactory. From 2 in. upwards, Lumeter measurements showed the illuminating power to be increasing approximately in proportion to the increased gas delivery. At the highest pressure the mantle was fully illuminated; there was no evidence of wastage of gas above the mantle; and the burner was just short of making a noise. Even if the burner had been capable of injecting a greater quantity of air, it is highly probable that the air shutter would have been closed to reduce the degree of aeration to about the above value, which seemed to represent almost ideal working conditions for the burner, mantle, and gas in use. (See also burner No. 3). It is clear, therefore, that the satisfactory operation of the burner was very dependent upon a secondary air supply. The reduction in the gas rate at a given pressure with the lighted burner was due to heating-up of the gas nipple by conduction and radiation. The superheater head was estimated to have a temperature not far removed from 200° C. at the highest gas rate.

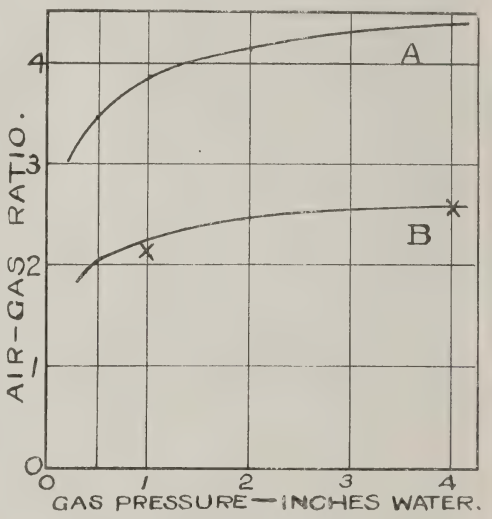

Fig. 12.—Burner of Fig. 1.

At 2½ in. pressure, the mantles being removed, the flames from the nozzles shot downwards to a length of 2½ in., with well-marked inner cones half-an-inch long. The observed air-gas ratio was 1·96, and is marked "x" on fig. 13. The increase in aeration above the corresponding pressure-point on curve B must not be ascribed to the removal of the resistance presented by the mesh of the mantle (see above), but rather to a reduction in the superheater and nozzle temperatures, the heat generated being less favourably placed for raising their temperatures than when generated in the confined space bounded by the mantles. It is noteworthy that at no time was any flame visible below the mantles, although removal of them would show long flames from the nozzles, and puncturing the mantles with holes of any size (say ⅛ in. dia. and upwards) always allowed flames to come through. Surface combustion on the mantle fabric with the aid of secondary air is probably, therefore, an important factor in determining the illuminating

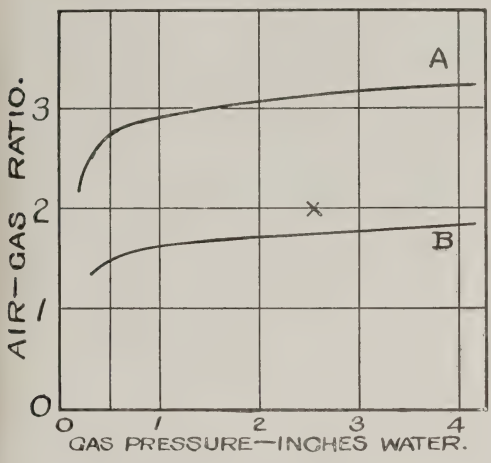

Fig. 13.—Burner of Fig. 3.

power. In this connection a careful exploration was conducted of the region around one of the mantles when the burner was operating at 4 in. pressure. Samples were drawn from the points indicated on fig. 14, and were at once analyzed for CO_2 in the large Haldane air-analysis apparatus. The dotted line, approximately $\frac{1}{4}$ in. away from the mantle, runs through points representing CO_2—concentration of 0·5 p.ct. As the undiluted products of combustion would contain about 12 p.ct. of CO_2, there must be an ample excess of air along the line thus mapped out. The method of sampling would not permit of closer approach to the surface of the mantle than $\frac{1}{4}$ in.; but it is plain that secondary aeration can play an important part in the operation of lighting burners, and that a considerable proportion of the necessary air can be effectively applied in this manner.

Street Lighting Burner (No. 3).

Burner No. 3 was a street lighting burner of a different type, but also fitted with a superheater head (figs. 4 and 5). It differed from the Manchester burner

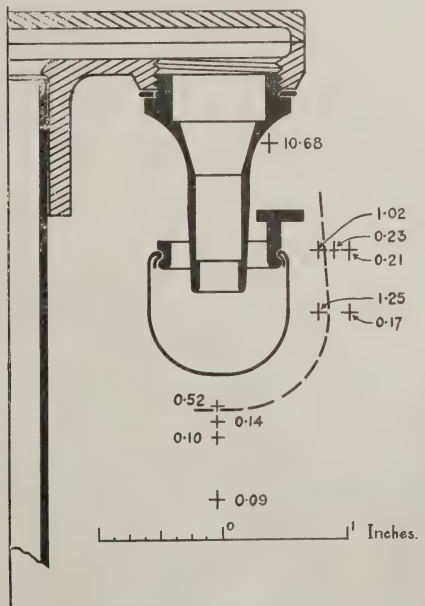

Fig. 14.—Distribution of CO_2 outside mantle. Figures indicate percentage of CO_2. (Burner of Fig. 3).

in being fitted with a variable nipple, and the long swan-neck bend of small bore ($\frac{3}{8}$ in.) connecting the nipple with the burner head might be expected to offer a considerable resistance. Immediately above the gas nipple the tube was still further contracted by a small funnel-shaped throat tube $1\frac{1}{4}$ in. long and only 9/32 in. dia. as shown in fig. 6. The two mantle nozzles were transferred from the Manchester burner to this one, so that the final outlet resistances should be identical for both burners.

The aeration curve for the unlighted burner was of the usual type, though not identical in shape with that of the previous burner. It will be observed that the gases used with burners Nos. 2 and 3 had about the same specific gravity, and that the gas rates at equal pressures were closely similar. The degree of aeration with burner No. 3 unlighted, however, was only about 90 p.ct. of that with burner No. 2.

The results obtained with the lighted burner (II.) presented a feature of interest, in so far that a maximum degree of aeration was attained between 2 and 3 in. pressure. This was not an unreasonable result, for with this burner unlighted, and with the other burners also, the air-gas ratio was increasing only slowly with pressure above $2\frac{1}{2}$ in. w.g. At the same time it was known that the heating-up of the burner caused a marked diminution in the air-gas ratio—with quantities so delicately balanced it was quite possible for the adverse thermal effect to exceed the injector effect and yield a reduced air-gas ratio upon increasing the pressure, and consequently the thermal delivery. An attempt was made to reproduce this phenomenon; but it was not exhibited by curve C, fig. 15, which conforms with the others.

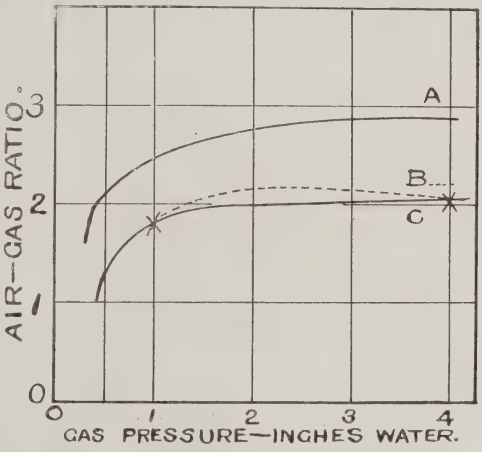

Fig. 15.—Burner of Fig. 4.

It was found that upon lighting-up from the cold this burner always went through the same cycle of changes. At first the burner was silent, and the velocity of the more highly aerated mixture of the cold burner was sufficient to maintain a stable flame. After some three minutes the nozzles and superheater warmed up, the air-gas ratio fell, the rate of flame propagation increased, probably to a greater extent than the rate of mixture flow (due to thermal expansion in the superheater and nozzles), and the burner became noisy and unstable.

Shortly after this, the illumination of the mantles would fall-off appreciably. The illumination could be restored by temporarily closing the air ports, afterwards opening them fully again, when good illumination would be obtained almost indefinitely unless some trifling hiatus in the action of the injector caused a resumption of the inferior illumination conditions, which then became permanent. Eventually it was discovered that when the illumination fell-off in this way the burner was operating in a partially " struck back " condition, the gas burning just inside the nozzle (or possibly as far back as the gauze), which became extremely hot. The effect of a

temporary closing of the air ports was to supply a mixture with a lower rate of flame propagation, while still maintaining a considerable rate of mixture travel. This brought the flame outside the nozzle, which cooled somewhat, and stable conditions were obtained—very delicately balanced, it is true—with the flame outside the nozzle. The point is one of considerable practical importance in burner adjustment, particularly when critical adjustment for maximum efficiency is being attempted. Thus, it is possible to allow a burner to become hot, and then adjust it on the photometer bench to maximum efficiency, apparently in a perfectly stable condition. If now the burner is extinguished and allowed to cool, it may not be possible for it automatically to resume its former illuminating power when lighted, owing to the necessity for passing through an intermediate condition on warming-up, which would give rise to the partially "struck-back" condition referred to above. At 4 in. pressure we have been able to obtain two air-gas ratios with this burner, a higher one corresponding with the flame outside the nozzle and lying above curve B (fig. 15), only obtainable by adjustment of the hot burner, and the other represented by curve B, corresponding with a partially "struck-back" condition. On the whole, curve C lies slightly below curve B; but this is in part due to the lower specific gravity of the gas used for the tests of curve C.

Burners Nos. 2 and 3 were used at about the same gas rates with the same mantles and nozzles. From comparison of fig. 13, curve B, with fig. 15, curve C, at say 3 in. pressure, it would seem that the difference between 1·8 and 2·0 c.ft. of air per c.ft. of gas, for gas of the quality used, represents the margin between safe working and unstable working due to "over-aeration," although even the higher figure represents only one-half the air theoretically necessary for the complete combustion of the gas, injected as primary air. It will be noted that the reduction in air-gas ratio of the lighted as compared with the unlighted burner is rather smaller with this than with the Manchester burner. This is doubtless due to differences in the design of the superheater and the disposition of the mixing tube.

A brief examination was made as to the effects of air-port adjustment upon the behaviour of this burner. It is plain that the air shutter is only one of a number of resistances to be overcome in working the burner, and much will therefore depend upon whether, in its fully open position, it constitutes the main, or any considerable proportion of the whole resistance of the burner. The air ports of this burner consisted of four holes 7/32 in. dia., with a total area of 0·150 sq. in. They could be closed by a threaded cut-off ring taking six complete turns to close the air ports entirely. As the ring was obscuring circular openings, the reduction in air-port area per turn was not uniform. The results of tests with three air-port adjustments are indicated in Table 4 (iv). The first result for the fully open air ports shows an air-gas ratio in good agreement with curves B and C already obtained. The burner was slightly noisy. Upon reducing the air-port opening by half (i.e., 3 turns of ring) the illuminating power was increased, and the air-gas ratio fell, but only by a trifling amount—2 p.ct. This may be contrasted with the 20 p.ct. change brought about by half-closing the air shutter of the Manchester burner. A further turn of the ring reduced the air-port area to one-third of its original amount, but the air-gas ratio had only fallen by 5 p.ct. in all, and the illuminating power of the burner was excellent. It is clear that for 6 turns—i.e., complete shut-off—the air-gas ratio would be nil. Practically the whole of the effective regulation of aeration, therefore, fell upon the last two turns of the ring; and if the original maximum air-gas ratio was low, it could clearly not be ascribed to insufficient air-port area in this case.

Further, these figures and those obtained with other burners show very plainly that the degree of aeration is *not* proportional to the area of air-shutter opening provided. Other workers also have shown that the relation between air-port area and degree of aeration for given conditions of operation must be determined for individual burners, and that the degree of aeration is not proportional to air-port area. Nevertheless, the contrary erroneous view, that aeration is proportional to air-port area, is still sometimes encountered.

UNIVERSAL REVERSIBLE INVERTED BURNER (No. 4).

This series of tests was conducted with a domestic burner designed to take the popular "universal" inverted mantle. The burner used is illustrated in figs. 7 and 8. The nipple points upwards, injecting into a tube of 13/32 in. bore, bent at right-angles, delivering into an aluminium alloy casting, which in its turn carries the refractory nozzle for the support of the mantle. Such burners are intended for attachment to brackets, etc., which previously carried upright fittings. The burner could also be reversed as shown in fig. 8. Illuminating power tests had already been made at Uddingston with this type of burner (2nd Report, Gas Investigation Committee, pp. 280-284, burners 5, 6, and 7), but the main reasons for its selection for aeration tests were that on account of its position the injector would keep relatively cool during operation of the burner, and the air supply was drawn from a region not likely to be mixed with products of combustion. In these respects it is in strong contrast to the type of burner next to be tested (see burner No. 5), although the latter is possibly the more common. The nipple used with the upright burner No. 1 was attached to this burner, and was worked at practically the same gas rates and pressures. As 6 c.ft. per hour may seem a high gas consumption for a universal inverted mantle, even with due allowance for the C.V. of the gas used (466 B.Th.U. gross), it may at once be noted that at this consumption there was no visible wastage of gas above or about the mantle, and

the gas rate might with advantage have been still further increased.

Exit of mantle nozzle ⅝-in. diameter—*i.e.*, 0·110 sq. in.
Diameter of globe gallery, 3⅜ in.

The aeration-pressure curve for the unlighted burner calls for little comment. It does, however, illustrate the difficulty of talking of the injecting power of a nipple or jet as a separate property. Comparing Tables 2 and 5, for example, we have the same nipple delivering gas under almost identical conditions as regards specific gravity and pressure, but into different burners. In the case of the upright burner, the air-gas ratio was 4·4 at 4 in. pressure, while for the inverted burner it was only 3·0, this proportion being retained approximately over the whole pressure range.

Owing to difficulties with back-firing, it was not possible to complete the comparative tests with the lighted burner and fully open air ports over the whole pressure range up to 4 in. w.g. The air ports consisted of two holes ⅜ in. dia. (total area, 0·220 sq. in.), and, for the pressures above 2 in. w.g., the available air port area was reduced to 0·165 sq. in.—*i.e.*, 75 p.ct. of its original value. From previous experience it was assumed that this would not reduce the aeration by more than 5 to 10 p.ct., but it permitted the gas to be burned effectively in the burner, and the aeration line with the ports

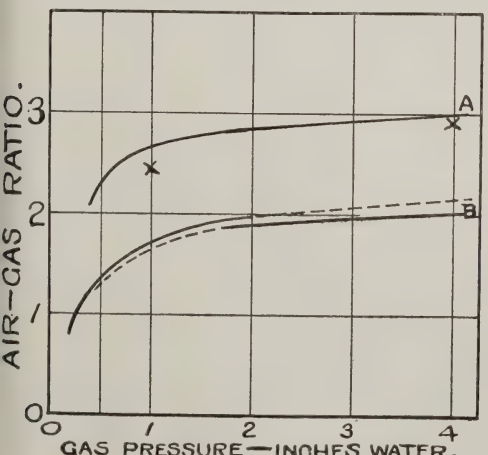

Fig. 16.—Burner of Fig. 7.

fully open (had the gas permitted it) would probably have been not far removed from the dotted line B on fig. 16.

In other respects the curves presented no unusual features. Once again, however, it was found necessary, in order to secure satisfactory combustion of the gas, to cut down the primary air supply below that which the burner was capable of injecting, and considerably (50 p.ct.) below that theoretically necessary for the complete combustion of the gas.

It was hoped to test this burner with the injector working in the inverted position as shown in fig. 8. From examination of the burner some little doubt existed as to whether the regulating pin would retain its exact location in the nipple when thus inverted, and the tests should preferably be carried out in the two positions with a burner injecting by means of a fixed orifice. For what they are worth, however, the results of two tests are indicated by "x" on fig. 16 for the unlighted burner injecting downwards. They are both clearly below curve A—a result which would be consistent with the extra load thrown upon the injector in working against the up-cast effect of the relatively light mixture which fills the tube between the mantle nozzle and the nipple. That the nipple becomes appreciably heated with this burner will be seen from examination of the relative gas rates at equal pressures for the lighted and unlighted burners.

INVERTED BURNER (No. 5).

This burner was of a type which probably represents by far the greater number of inverted gas burners in use to-day. The nipple was a variable one injecting downwards into a relatively short mixing tube, and a universal mantle was used.

The burner was a high-class article, and the injector was constructed of relatively few parts, all machined from the solid and carefully assembled. The general dimensions can be judged from fig. 9, the external diameter of the globe gallery being 3¾ in.

With this burner, alternative nozzles were used. The first was of the usual type with an outlet ⅝ in. diameter. It will be seen from fig. 10 that this nozzle projected only a short distance into the mantle. The second nozzle was of the more recent pepper-box type, perforated with 31 holes, each approximately 1/16 in. dia. The total outlet area was thus slightly less for the pepper-box nozzle than for the plain nozzle. It will be seen from comparison of figs. 10 and 11 that the pepper-box nozzle projected considerably further into the mantle than the plain.

The investigation of such a burner presented new difficulties, both in making the experiments and in interpreting the results. The injector, on account of its position, became very hot, as was shown by the difference in gas rate for equal pressures with the lighted and unlighted burner. Most manufacturers provide such burners with deflector plates, either of metal or of refractory material, immediately below the air-intakes. For practical and for æsthetic reasons such deflectors must be kept small; and it is doubtful whether they do more than protect the injector from flame with consequent firing of gas at the nipple, or from a very hot and concentrated stream of products of combustion. It is certain that a burner of this type draws its primary air supply from a region containing products of combustion. In considering injector efficiency, therefore, it may be necessary to credit the injector in the first place with all the mixture which it causes to circulate through the burner, irrespective of its composition. Of the quantity circulated, however, only part can be regarded as "fresh air" carrying with it the usual proportion of oxygen for combustion of the gas, and may be rightly regarded as the "air-gas ratio" of the burner for purposes of combustion.

These two quantities can be differentiated by determining, in the mixture samples, first the free CO_2 (partly derived from that already present in the unburned gas, and partly from admixed products of combustion) and secondly, the CO_2 produced on completing the combustion of the mixture over copper oxide. The calculations are indicated in Appendix II.

The first tests were made at 1 in. and 4 in. w.g. with the plain nozzle and the air shutter fully open, the gas

being unlighted. The results are indicated by "x" on fig. 17, and show a relatively high air-gas ratio, 3·7 to 3·8. The burner, however, would not operate with this degree of aeration, every attempt to light it being accompanied by a vigorous back-fire. The air shutter was therefore closed until the gas would burn with slightly noisy flames, which would ordinarily be described as "well aerated." The burner was allowed to cool down and the tests with the unlighted gas were repeated with the air openings thus restricted. The air-gas ratio was reduced to about 62 p.ct. of the value obtained with the fully open air shutter, although the air-port area was reduced to 20 p.ct. of its former value.

The burner was then tested with the gas lighted; the results being indicated by Table 6 (iii) or Curve B, fig. 17. The first point to observe is that, although the nipple was untouched between tests (ii) (gas unlighted) and tests (iii) (gas lighted), the heating-up of the burner in the latter tests was sufficient to reduce the gas rate by an amount ranging from 9 p.ct. at ½ in. pressure to 15 p.ct. at 4 in. pressure, the drop being progressive with increasing thermal development at the mantle. This type of burner, with the gas nipple immediately above the nozzle, exhibits the phenomenon to a more marked degree than any of the others. The temperature of the gas passing through the nipple might be roughly estimated from this drop in gas rate as about 100° C. Curves A and B, fig. 17, are of the same type, although the aeration falls away more rapidly and the shoulder on Curve B is less marked below 2 in. pressure, due to the modifying influence of thermal effects. The amount of air taken in as primary air with the burner in its normal working state was, as in previous examples, only about one-half the total theoretical air requirement of the gas. The air-gas ratios given are for air of normal composition. In the last column of Table 6 the amount of products of combustion taken in with the primary air has been calculated, and should be added to the air-gas ratio values to determine the total volume of mixture injected. From the analysis of the gas "M," Table 1, the products of combustion would have the following composition by volume, and the figures in Table 6, for the volume of products of combustion injected, assume the water formed during combustion to remain as steam.

CO_2. . . 10·4 p.ct.	H_2O (as steam) 20 6 p.ct.	N_2 . . 69 0 p.ct.

The amount of products of combustion drawn into a burner would be proportional to the quantity of air drawn in (*i.e.*, the air-gas ratio) and to the concentration of the products of combustion around the air-intakes of the burner. It will be observed that the amount of products of combustion injected in our tests ranged from 1 p.ct. of the gas volume at ½ in. w.g. to 8·4 p.ct. of the gas volume at 4 in. pressure, and this would have the same effects, so far as combustion is concerned, over the usual working range of the burner, as the addition of 7 to 8 p.ct. of inerts to the gas. As a matter of fact, it is possible to estimate the concentration of the products of combustion in the primary air supply, by dividing the volume of products taken in per c.ft. of gas by the sum of this quantity and the air-gas ratio. When considered in this way, and having regard to the proximity of the injector to the burning gas, the amount of admixture of products of combustion with the primary air supply is surprisingly small, amounting in these tests to only 2 to 3 p.ct. by volume of the air supply over the range 2 to 3 in. pressure. Actually, the figures show that the concentration of products of combustion in the primary air supply increases rather more rapidly than the rate at which gas is burned; but the quantities involved are so small that our determinations do not

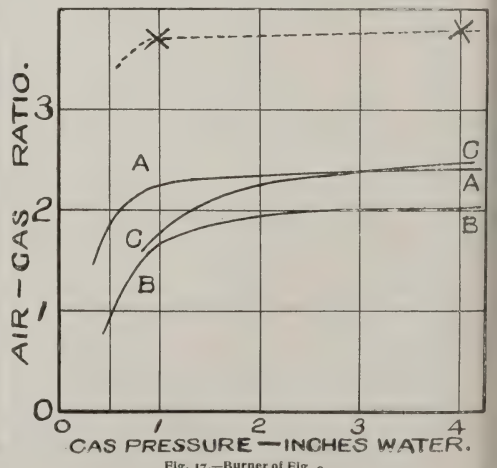

Fig. 17.—Burner of Fig. 9.

permit of more than a qualitative statement in this respect.
